First Four Centuries of Slovenian Vacuum Techniques

Author: **prof. dr. Stanislav Južnič**

Translation: prof. dr. Stanislav Južnič (DZTPS accredited Translator no. 216-301/20)

Proofreader: prof. dr. Stanislav Južnič

Editor: dr. Peter Panjan

Layout: dr. Peter Panjan

Publisher: Slovenian Society for Vacuum Technique

For the publisher: prof. dr. Alenka Vesel

Ackknowledgment: We thank Slovenian Research Agency (ARRS) for financial support of this edition

Kataložni zapis o publikaciji (CIP) pripravili v Narodni in univerzitetni knjižnici v Ljubljani
COBISS.SI-ID=44183043
ISBN 978-961-94431-1-8 (pdf)

<u>Cover photo</u>: The experiment of Guericke and prince Auersperg of Carniola with Magdeburg hemispheres conceived by the professor at the Zagreb Higher Real School Slovenian Ivan Tušek (* 1835; † 1877) two centuries after the first experiments in his translation of Schoedler's Physics in Ljubljana in 1869 on page 94, figure 111 (page 82 of original print in Braunschweig in 1865).

This book is dedicated to the teacher of us all, Jože Gasperič (1932-2019), who have played a decisive role in the education of Slovenian experts for vacuum science and technique

This treatise is published to celebrate the 350th anniversary of return of the first Slovenian experimental researcher of vacuum Janez Vajkard Auersperg (Turjaški) to Ljubljana-Žužemberk in 1669/70, and 60th anniversary of establishment of Society for Vacuum Technique of Slovenia (DVTS) and its journal Vakuumist)

Index of Main Topics

I. Prelude: Philosophical Beginnings of (Seemingly Impossible) Vacuum

II. Fugue: Pumping & Measuring of Vacuum Related New Materials

III. Intermezzos: Export of Vacuum Designs into Foreign Lands & Unexpected Uses

IV. Arias: Vacuum for Advanced Industries, Sciences & Entertainments

V. Finale: Organizing Vacuum Researchers & Backfired Philosophical Issues

Detailed Index as Table of Contents

Reviewer's Opinion

In the book Vacuum and Vacuum Techniques History, dr. Stanislav Južnič presents insights into the history of the vacuum research and history of the developments of the vacuum techniques he gained while studying archives both at home and abroad. The book is extensive, comprehensive, and it is intended for readers with a technical background who are also interested in the history of science. The contents of the book have mostly been published in the period 1993-2000 in Vakuumist, the bulletin of the Society for Vacuum Technology of Slovenia, and in three books written by dr. Južnič entitled History of Vacuum Research and Vacuum Techniques, Parts 1, 2 and 3, also published by the Society for Vacuum Technique Slovenia in 2004, 2010 and 2017. Some contributions were also published in some other publications.

Since vacuum techniques have been integrated into practically every field of the natural sciences until the 20th century, this work describes the whole history of physics, chemistry and related sciences. In his extensive work the author gives a historical overview of the world achievements in the field of vacuum sciences. He also provides a broad overview of the achievements of all those scholars who have worked in the region of present-day Slovenia in the last four centuries. Južič's conclusion is that these scholars did not lag far behind their neighbors and that they even exceeded them in many ways. Many of these scholars are described and documented in detail in this book, like who their teachers were, their classmates, from which textbooks they were learning, and what teaching aids they were using. Of course, we can find out what kind of books have been published in the field of vacuum techniques as well as in other areas. Dr. Južnič also describes who their friends, supporters and opponents were. Also interesting is the fact that, at that time, these scholars worked very intensively with their colleagues in the European area as well as beyond. This is especially true of the close collaboration of the first Prince Janez Vajkard Turjaški (Auersperg) born in Žužemberk with the inventor of the vacuum pump, Otto Guericke. Special attention in this book is given to an overview of the books related to vacuum, which were accessible and present in the Slovenia region. They were mainly available in the libraries of monasteries and some of them in private libraries. In this work is described an important role of Jesuits primarily engaged in science on the Slovenian region in the period from the 16th to the 19th centuries. The natural sciences were only part of their interest. However, the author of the book deals with their work in its entirety, so we find many interesting things in other fields of science where Jesuits were active. The author also described the importance of Slovenian Jesuits in the spread of European science to China and Japan, especially the significance of Augustine Hallerstein. The book also contains interesting descriptions of vacuum in period of Baron Zois, technology used by Janez Vajkard Valvasor, role of the Idrija mercury for vacuum barometers, measuring devices made by Tobias Gruber, brother of the better known Gabriel Gruber, builder of the Ljubljana Canal and General of the Jesuit Order and many other interesting matters. This book also contains numerous archival papers on Johann Philipp Neumann, the first professor of physics at the Faculty of Philosophy in Ljubljana and a pioneer of vacuum techniques in our space. Also interesting are the archival documents on the first Slovenian airplane and balloonist Gregor Kraškovič. His pioneering achievements in aviation, as well as in the field of vacuum engineering, can be our pride today. The vacuum related research performed by Jožef Stefan is also described and discussed in the book as well as the achievements of Baron Codelli in the field of the vacuum elements for television.

As basic phenomena related to vacuum were explored, the unprecedented evolution of technological use of vacuum also began, culminating in the 20th century in various industries, from metallurgy to electronics and aerospace, and basic particle research in high energy physics. In the book, the author describes the history of some of the most essential vacuum technologies used today (thin-film vaporization and sputtering, vacuum metallurgy, microelectronics, semiconductors, domestic household applications of vacuum, vacuum isolation, television... Among basic scientific areas related to vacuum author described topics like X-rays, electron microscopes, accelerators, plasma physics…… Especially in detail, the author of the book discusses the achievements of Nikola Tesla, in particular, those related to vacuum technology since Tesla spent a short period after his studies in Graz in Maribor. Today's experimental physics cannot be imagined without the use of vacuum technology. Dr. Južnič highlighted the achievements of Professors Peterlin, Osredkar, Blinc and Strnad, who contributed significantly to Slovenian science in the second half of the twentieth century. The author describes the events and the circumstances of the founding and the first years of operation of the Jožef Stefan Institute and some other Slovenian institutes and related organizations like the Institute of Electronics and Vacuum Technique and Slovenian Society for Vacuum Technique.

The author also presented the reflections of Slovenian philosophical physicists (Dolenc, Detela) who touched on "emptiness" in their works, including the author's interesting thinking about vacuum as limits. In the book is demonstrated the Toynbee-Kuhn-Juznic method to illustrate the development of vacuum techniques.

This book is a popularly written scientific presentation of the development of vacuum science and technology in the world and in our country. It should be mentioned that this work also contains many copies of documents on important vacuum devices in Slovenia and worldwide as well as a very extensive list of archival materials that the author has collected for many years in domestic and foreign archives. Access to the Vatican archives and other archives in Europe and America was made possible by the University of Oklahoma, which also supported his research.

The book Vacuum and Vacuum Techniques History, written by dr. Stanislav Južnič is a nice walk through the history of vacuum science in present-day Slovenia territory and the wider neighborhood. We can be grateful to the author who has put a great deal of effort into preparing the great book in a history of “vacuum”.

Prof. dr. Janez Kovač

Reviewer's Opinion

Stanislav Južnič physicist and historian, was born in San Francisco. After his schooling in Belgrade and Ljubljana, he graduated from the Department of Technical Physics at the University of Ljubljana and received his master's and PhD degree in the history department of the University of Ljubljana, Stanislav Južnič dedicates the life of the history of Physics and other natural sciences.

In the book *Vacuum and Vacuum Techniques History*, author presents insights into the history of the vacuum research and history of the developments of the vacuum techniques. The book is very comprehensive and extensive and is dedicated to teachers, students, and researchers with technical background. The book contents have mostly been published in Slovenian language in the period 1993-2004 in Vakuumist, the bulletin and Journal of the Slovenian Vacuum Society, and in three books written by Južnič entitled History of Vacuum Research and Vacuum Techniques, Parts 1, 2 and 3, also published by the Slovenian Vacuum Society (DVTS- Društvo za vakuumsko tehniko Slovenije) in 2004, 2010 and 2017, some contributions were also published in other publications.

His basic field of research is the physics of Carniolian Jesuits and their students seventeenth and eighteenth centuries. He is a researcher from the University of Oklahoma and the Scientific Research centre of SAZU, Ljubljana and examines the European books in USA. In the previous century, the Americans bought a huge amount of old European books, even the books of Galileo with his personal signature are in the library of the University of Oklahoma. Unlike the more advanced USA, there is no chair for the History of Science sciences in Slovenia. At Saint Louis University and at the University of Oklahoma Science Stanislav Južnič studied the worksof Carniolian Jesuit-astronome of Augustus Hallerstein in Beijing (2002), the scientific, military and freemastean activity of Jurija Vega (2003) and the extraordinary successes of the professor of astronomy Gabriel Grubert (2004). At the International Year of Astronomy, he completed his trilogy on the history of accurate science in Slovenia with Astronomy (Radovljica: didact: 2008), Physics, and Mathematics (2009). He is interested in the links of Ljubljana jesuites with their rich donators' princes of Turjak, Baroni Enberg and the scientific design of the Jesuit Janez Vajkarda Valvasor.

He has published over three hundred scientific works in Slovenia, Croatia, Poland, Serbia, Russia, England, and the United States. Južnič received the wider attention of the media in 2006, when in the Ljubljana National and University library discovered a valuable copy of the book De Revolutionibus of the Polish astronomers Nikolaj Copernicus of 1566, which due to the error in cataloguing was stocked and forgotten.

After the first two parts of the history of vacuum exploration and vacuum techniques with collected announcements from years 1993-2004 and 2005-2010, the author Stanislav Južnič prepared the third part of the trilogy: the development of vacuum research and vacuum techniques (at UNESCO-known year dedicated light and related technology, and at the four-century birth of the first Carniolian vacuum of Janez Vajkard of Turjak

The author described in detail the first three decades of Ljubljana experiments with vacuum techniques within the newly established higher physico-mathematical cabinet. The first in historinography was used by the partial Mihael Peternel's description of the initial Bernard Ferdinand Erber devices drawn before the second century, Gabriel Grubert's orders from 1768, the lists that Anton Ambschell signed in 1779 and 1785, and a list of new purchases between March 1781 and March 1782.

The author has thus emphasised the role of Carniolian society and the Society for Agriculture and useful Arts in the financial support of vacuum pumps and other research equipment purchases. From the dynamics of purchases then modern vacuum technology and related experiments and maintenance devices, he attempted to exfoliate the prevailing scientific tendencies and the direction of the holders of the Ljubljana School of Physical-mathematical sciences.

The author also describes the beginnings of the use of vacuum technologies in the Slovenian area of IJS and mentions the Society for the vacuum technique of Slovenia, which was co-founder of the Yugoslav Vacuum Society (in addition to France, the United states, Spain, Great Britain, Germany, Belgium, Japan, Sweden and the Netherlands) International Union for Vacuum Science, Technique and Applications - IUVSTA in 1958 and in 1962 in today's IUVSTA whose main areas are (see: http://iuvsta-us.org/iuvsta2/index.php?id=468) useful science on surfaces: Applied Surface Science (ASS), Bio Interface (BI), Electronic Materials (EM), Nanotechnology (NM), Plasma Science (PST), Surface Engineering (SE), Surface Science (SS), Thin Films (TF) and Vacuum Science and Technology (VST).

Monograph Vacuum and Vacuum Techniques History of the Slovenian author Stanislav Južnič is a historical representation of the functioning of Slovenian scientists and their cooperation with top scientists in the 17th century. and 18th century. At the same time, it shows excellent equipment with research infrastructure and scientific literature, which was collected by scientists in several private libraries. The monograph is fundamental to the further development of the scientific technical scientific area and the importance of presenting Slovenian science achievements in the domestic and international space as well as for the dissemination of new scientific knowledge and scientific culture.

The book contains many copies of documents on important vacuum devices in Slovenia and worldwide as well as a very extensive list of archival materials that the author has collected for many years in Slovenian and foreign archives. Access to the Vatican archives and other archives in Europe and United States of America was made possible by the University of Oklahoma, US, which also supported his research.

The book Vacuum and Vacuum Techniques History, written by Stanislav Južnič is review of the history of vacuum science in Slovenian territory and the west and central Europe. The book is important from the scientific and historian point of view and it worth to be published in English.

Prof. dr. Monika Jenko

I. Prelude: Philosophical Beginnings of (Seemingly Impossible) Vacuum

1 Foreword as Introduction

In front you, my dear reader, you may find a book that was created during the long decades between 1993 and 2020 following the Slovenian Independency. Its parts were published in Vakuumist, the bulletin of the Society for Vacuum Technology of Slovenia the newspaper for the vacuum technique and technology, vacuum metallurgy, thin films, surfaces and plasma physics. Some of the studies were adapted in a popular form for the magazine Life and Tech (Življenje in Tehnika) and others. While the tripartite Slovenian version of this book was published to promote the self-confidence of local Slovenian researchers and users of vacuum technique, the English language translation is here to promote the Slovenian merits worldwide after three decades of hard works.

There are lots of histories of research of vacuum published before this one. They focused technological or philosophical-theological aspects, or both. Why on earth do we need another one? There is one main reason: here, for the first time in historiography, we primary concentrate on the reception of vacuum-related issues in some limited geographical area. That area is called Central Europe, or, more precisely, Slovenia. There is also a nationalistic point in it: we wish to suggest, that all kinds of sciences including vacuum researches were never exclusive domain of Anglo-Saxon part of humans. In this stage of research, it is not quite possible to determine all the merits of non-European people, while the Slovenian contributions are much clearer. And they are not at all some minor obscurities, as the following narration tries to prove. Regretfully, at this point there is not much to be narrated about the probable vacuum techniques of Aborigines, Pacific Islands people and Sub-Saharan Africans, while just some sporadic information are provided about the Native American lyophilization or lapis nephriticum, Near Easterners' development of Hellenic vacuum and overpressure technologies or the Far Eastern Oriental ideas about vacuums and zeros focused on Kerala areas in India. A little more is provided about Chinese and Japanese early borrowings of European designs of vacuum technologies and luminescence. Those faults are not just the consequences of our Eurocentrism, but also a regretful consequence of the lack of historical research and data about the Non-Europeans worldwide up to now.

Let us introduce the author. As a future physicist and historian, he was born and raised in San Francisco as a typical Frisco kid. The white one with a colored heart. After studying in Belgrade, Ljubljana and Minsk, he graduated from the Department of Technical Physics at the University of Ljubljana at the class of an academician prof. dr. Robert Blinc. He received his master's degree and doctoral thesis at the Department of History of the University of Ljubljana by the academician prof. dr. Vasilij Melik. His postdoctoral positions were all in his native USA. He dedicated his life to the history of physics and related natural sciences. His basic field of research is the physics of Carniolan Jesuits and their students of the seventeenth and eighteenth centuries. He loved to be a researcher at the Universities of Saint Louis and Oklahoma, of the Ljubljana institute of Mechanic, physics and mathematics and the Scientific Research Center of the SAZU as well as the interpreter of Slovenian cultural heritage for Slovenian government as the chief of Slovenian Jesuitical archives. He enjoys studying European books in America as the head of the archives of the Jesuit province of Slovenia and as the interpreter of cultural heritage of Slovenian government. In the previous century, the Americans picked up the huge decisive amounts of old European books, and even Galileo's books with his personal signature are in the library of the University of Oklahoma. In Slovenia, in contrast to the US, there is no chair for the history of natural sciences.

The fiftieth anniversary of the death of Slovenian inventor of Codelli's Television and the 350th anniversary of the famous Guericke's vacuum experiment in cooperation with Slovenian prince Auersperg was a real opportunity to present our work to the Slovenian readers in 2004. We tried to cover as wide research area as possible, of course, a piece of each of it. For every direction of modern research of vacuum, we have searched for its roots in the past, so there may have been some repetition and intertwining.

We have repeatedly tried to highlight the important contributions of Slovenian researchers. The chapters about individual areas in the book do not follow the chronology of the papers published in Vakuumist journal. We decided to prefer the historical method, because the entropic time arrow is a master of us all. Thus, the technical part of this book begins with a longer chapter on the development of vacuum technologies, like pumps and meters, with special emphasis on Slovenian researchers. Then follow the fundamental discoveries in individual fields of research: "cathode ray", vacuum metallurgy and thin films, vacuum balloon, radiometer, thermos flask, bulb, X-ray cathode ray tube, electron microscope, accelerator, cathode ray tube in television, transistor, plasma, and much more. Apart from the radiometer, balloons, thermos, luminescence and few other chapters, everything else is closely related to the use of the vacuum discharges leading to cathode-ray tubes. We discussed the luminescent substances only in so far as we use them for television or computer screens.

After the first part of the History of vacuum research and vacuum techniques in which we collected publications from 1993-2004, its advanced path was available at the second part. We kindly ask you for a blatant benevolent reading.

The second parts of this story were published in 2004-2010 in Vacuumist of the Society for Vacuum Technique of Slovenia, the Journal of Vacuum Science, Technique and Technology, Vacuum Metallurgy, Thin films, Plasma Surfaces, and Plasma Physics. Some surveys were published in a popular form for the magazine Life and Tech; others were published by the Japanese Historia Scientiarum and many other newsletters in all continents. But most of the collected texts have not yet been able to see the light of the world in a book form in English language. Therefore, it may seem right to pick them up here in one place. The 400th birthday of the first Slovenian vacuumist, Prince Janez Vajkard Auersperg, is perhaps the right opportunity for this kind of reading.

Two of the discussions in Vacuumist were published in cooperation with Vinko Nemanič and Andrej Pregelj. All papers were proofread by Jože Gasperič and edited by Peter Panjan and Miha Čekada. Franc Jurkovič, Albin Wedam and Branko Ozvald told us much about Codelli's television. Most of our ideas were critically examined and supplemented by the oldest Slovenian vacuum researcher, Alojz Paulin. When searching for the right words, I always used a help of my daughter Urška. The Society for Vacuum Technique of Slovenia arranged the printing of our books. Money for research and print was given by the Ministry of Education, Science and Sport of Slovenia and the Mellon Foundation of the Universities of Saint Louis and Oklahoma. For our great encouragement, we are a part of the game which we researched, a kind of guests of honor of inner circle vacuum scientists. We are deeply grateful to everyone. Without their help, the world would be empty as a vacuum.

The vacuum has always been disturbed by cunning people, because the empty space is not something that we can see or touch. Vacuum is also not a completely abstract concept, as it can be pumped out, and we must attribute to it certain physicochemical properties.

In perceiving the vacuum, theoreticians and philosophers on the one hand and practitioners like experimenters, engineers or technicians developed completely different approaches of dealing with each other. For the first, the vacuum is a completely empty space, without any material particles. Thus, about 400 BC, Democritus, whom the Europeans treat as the founder of atomism, taught that all events in nature are an eternal movement of atoms in an empty space. In his statement, the knife cuts the bread because a vacuum is cut out between atoms.

The opposite view was that of Aristotle almost a century after Democritus. In every object, even in the innermost part of matter, Aristotle saw the presence of God; maybe a devil was in the space without substance. The dogma, that nature does not allow the devilish vacuum, sounded nice for the medieval Christian Church. That dogma ruled the mainstreamers until the end of the 16th century. It was reversed by Torricellian famous experiment towards the real vacuum under the influence of imported Indic concepts where vacuum was never a taboo.

For researchers and technicians, however, the vacuum is a state of diluted gas. We can talk about a vacuum when the pressure is lower than atmospheric pressure at the sea levels. By using vacuum pumps, only a "better" or "worse" vacuum can be achieved, since all traces of gases can never be completely removed from the vacuum receiver. The vacuum is evaluated by the pressure or by number of molecules in the volume unit.

Although in the atmosphere, which is the basis for the existence of life on Earth, there are wonderful observable things like wind, rain, cloud formation, lightning, the mysterious atmospheric pressure remained hidden from European perspectives for a long time. It was measured only by Torricellian experiments in 1644. A few years later, the famous Pascal completed Torricelli's experiments and laid down the laws which rule the air pressure. He sent his brother-in-law for the first measurements of the height of the hills with a mercury thermometer-barometer by comparing the pressures at the foot and at the top of the mountain.

In 1654 the German Otto Guericke demonstrated a famous experiment with Magdeburg hemispheres with the help of Žužemberk-born prince Janez Vajkard Turjaški-Auersperg. Around 1737, the Swiss D. Bernoulli explained the gas pressure in a container by the collisions of particles with the vessel wall, thus laying the foundations of the kinetic theory of gases. Significant great progress in the field of vacuum science took place in the second half of the 19th century. Many eminent European scientists of that time tried to discover the elementary particles of electricity by trying to discharge in evacuated tubes. The results of these experiments were remarkable. In 1852, during the exploration of discharges, the Welshman Grove noticed the sputtering dispersion of metals - i.e. the method of evaporation of metals, which in the form of thin films condenses on a cold basis. In 1892, the famous Edison used this sputtering process for metallizing matrices to make the gramophone records. In 1895, Röntgen discovered X-rays. Two years later, J. J. Thomson “discovered” an electron, and in the same year Braun's cathode-ray tube was born which soon became the basis for television. The last three discoveries were rewarded with Nobel Prizes while Edison or Tesla got none because the technically minded community sharply divided itself into moneymaking inventors and academicians with just sporadic actors active in both areas as William Thomson lord Kelvin. The gap separating scientists from engineers might not be that deep as the Charles Percy Snow’s dual cultural gap between sciences and humanities but it is evidently deep enough for unwanted divisions.

The carbon filament lamps, manufactured by Edison in the United States since 1879, produced a powerful impulse for the advancements of vacuum technology. The result of glow discharge research was also a fluorescent lamp, which enjoyed its commercial use only after 1938, on the outskirts of WW2. An important invention in the field of vacuum technology was also a Seebeck-Peltier’s thermocouple which gradually replaced clumsy Torricellian mercury thermometers. Dewar designed his first “thermos” flask in 1873.

After the First World War, the quick violent development of electronics began. In the mid-1930s, the use of vacuum expanded into metallurgy. After the Second World War, vacuum technology was an essential tool in the separation of uranium isotopes with thermo-diffusion and in the development of nuclear reactor materials. Vacuum technology was also indispensable in the development of accelerators and electron microscopes. In the 1960s, vacuum technologies enabled the development of lasers, optics, optoelectronics and microelectronics.

Research in the vacuum also made possible many fundamental scientific achievements: detection of isotopes by mass spectroscopy, confirmation of kinetic theory of gases, measurement of photoelectric emission (photoelectricity), confirmation of wave properties of electrons by observing their dislocation, etc.

New insights about the history of vacuum research and vacuum techniques came from archival studies. Since the 20th century, the vacuum techniques have been practically applied to all fields of natural science and engineering described in this work, in fact throughout the history of physics, chemistry and related sciences. In the first two parts of the trilogy published in Slovenian language, the emphasis was placed on the history of worldwide achievements in the field of vacuum science. In third part, we limited ourselves to describing the achievements of all those scholars who have worked in today's Slovenia in the last four centuries. All of this and much more filled our first two books of the history of vacuum research and vacuum techniques. In the third book, we describe the achievements of those scholars who have worked in today's Slovenia in the last four centuries and who used vacuum in their research. During the review of archival material at home and abroad, we reached many unpublished documents to prove that in today's Slovenia, until the middle of the 19th century, the researchers had developed strong technical intelligence, which was not overshadowed behind their neighbors, but in many ways even overcame them. The secret desire is that these Slovenian scholars, who were mostly members of the "foreign" nobility, would again be declared as "ours". We all think that Slovenian embracement could be right for them. And as the reader of this book can find out, there were many of them. The conclusion is that until the middle of the 19th century Slovenian scholars were not far behind the neighbors and they even exceeded them in many ways. In the turn of political struggles in 1848, the elite, from which they emerged, the nobility, was declared non-Slovenian, therefore a great brain-drain soon began. One of the purposes of this book is that the scholars who worked in the field of modern Slovenia must be once again declared as the Slovenians. This is especially true of the close cooperation between the first prince Auersperg and the inventor of the vacuum pump Otto Guericke, since the prince was born in Žužemberk and spent the autumn of his life in his Baroque palace on the site of today's NUK in Ljubljana.

We do not only talk about who these Slovenian scholars were and what were their achievements. We described and documented them in detail. We learned who were their teachers, classmates, from which textbooks they were taught and what teaching aids they used. Of course, we can find out which books in the field of technology (as well as other areas) they published. We even know who their friends were, who supported them and who were their opponents. It is also very interesting that those scholars already collaborated very intensively with their colleagues on European soil, and even in the wider areas. At the time from the 16th to the 19th century, mainly the Jesuits dealt with science on the Slovenian soil. The natural sciences were only part of their interest. However, this book deals with the whole aspects of their work which is why we are also interested in other areas of science. Since they filled first barometers and thermometers made in Florence in the 17th century with Idrija mercury, we also described in detail who led the Idrija mine at that time, what technologies they used and what kind of education system they had in Idrija. The first vacuum experiments were carried out in Florence with Idrija mercury. We must know that the authorities in Vienna sent the best experts to Idrija to improve the process of obtaining and processing Idrija ore. For example, Inzaghi as the manager of the Idrija mine at the 18th century and his close relative Alessandro Volta among the first supported vacuum novelties in the territory of today's Slovenia. The heads of the mine, especially Abondio Inzaghi and his descendant Franc Janez Inzaghi, the second cousin of the mother of Alessandro Volta, played an essential role in the distribution of Idrija ore. Franc Janez Inzaghi employed his first-class collaborators, including Janez Anton Scopoli, B. Hacquet and the Bohemian pharmacist Ernest Freyer. Alessandro Volta contributed to the progress of the Idrija mine with his exploration of gases. Volta’s relative Franc Janez Inzaghi, for his reimbursement, delivered to Volta a hefty amount of Idrija mercury required for production of barometers and thermometers at Volta’s new physical laboratory of the University of Pavia, where he received his chair two years after Scopoli. With their knowledge of the distillation and vacuum procedures for the cleaning of Idrija ore, the experts in Idrija also contributed to the good supply of Volta’s and Dutch vacuum pump manufacturers, including Musschenbroek who collaborated with

Herman Boerhaave, a teacher of many leading scholars at the Viennese court. The consumption of mercury for scientific purposes was not very great, but it greatly contributed to the prestige of the Idrija mine. Franc Janez Count Inzaghi achieved the decisive success at the end of his leadership of the Idrija mine due to enormous Spanish orders for amalgamation in Mexican and other Latin American silver mines. Due to connections with Inzaghi's relatives, Volta's rechargeable electrophorus and Volta's pistol eudiometer for measuring the quality of air spread remarkably fast, also into a collection of Ljubljana's higher education physics-chemical cabinet. Inzaghi stayed in touch with Volta even after his return to Graz, especially when Volta's wedding took place in 1794.

Our book also contains interesting descriptions of the vacuum measuring devices of Tobias Gruber the brother of the more famous Gabriel Gruber, the builder of the Ljubljana canal and General the Jesuit order. We also examined Tobias' scientific works as the vacuum gauges of his own production at that time were so reputable that he was repeatedly elected as president of the Bohemian Scientific Society, the forerunners of today's Czech Academy of Sciences. The younger brother of the general of the Jesuits Gabriel Gruber was the famous scholar-vacuumist Tobias. We presented Tobias inventions of vacuum measuring devices that were adapted for the field measurements. Tobias' scientific work, and especially handy vacuum devices of his own production, received such a resonance that Tobias was chosen three times for the president of the Czech Science Society. Early in 1804, Tobias Gruber renewed his vows as a Jesuits under the direction of his brother General Gabriel. He researched in Ljubljana and the wider Carniolan areas for four years, together with his brothers Gabriel and Anton who were more closely related to the city of Ljubljana.

We also published many archival documents about Johann Philip Neumann, the first professor of physics at the Ljubljana Faculty of Philosophy who wasn't a monk. He the pioneer of vacuum techniques in Slovenian areas. In addition to scientific discussions, he also wrote several textbooks, and he raised many successful successors. His best student was Janez Krstnik Kersnik (the grandfather of the known writer Janko Kersnik), who later conducted chemistry-physics lessons in Ljubljana for almost half a century. It is also interesting that Neumann was a close collaborator of the famous composer Franz Schubert. Among the professors of Ljubljana and researchers of vacuum techniques, Neumann is by far the most notable online and in the literature. Therefore, we can only agree that Neumann deserves a kind of memorial in Ljubljana or at least a street with his name.

The archival documents about the first Slovenian aeronaut and balloonist Gregor Kraškovič, published in this book, are also amazing. His pioneering achievements in aviation, as well as in the field of vacuum technology, make Slovenians proud even today. We described in detail the first Slovenian astronaut and beginner of ballooning Gregor Kraškovič. We emphasized the early Kraškovič's experiments on the implementation of a half-century-old idea promoted by A. Kircher's student Francesco Lana Terzi of Brescia focused on the flight under vacuum balloons. The first Slovenian balloonist died in the then suburb of Dubrovnik immediately after the new year of 1823. Complications with his will reveal the complexity of his private life, and even more so his scientific interest in vacuum technique. Although after the completion of higher studies he never fully returned to Carniola, the Slovenians are undoubtedly proud of his achievements.

One chapter of the book is dedicated to the famous physicist Ernst Mach. His father was a landowner in Veliki Slatnik of today's South Slovenia between 1858 and 1879. Ettingshausen's students reshaped many aspects of vacuum techniques, among them Stefan and Mach. Mach designed the first use of flash photography of supersonic missiles, which was carried out for him by Peter Salcher, a student of K. Robida, S. Šubic and A. Toepler. Robida was a pioneer of metal sputtering, while Ettingshausen and Toepler developed modern scientific photography. Both these achievements are used today to take photographs of complex plasma turbulences during sputtering of thin films with a magnetron. Mach's achievements in the photography of supersonic missiles enabled today's studies of plasma turbulences with the fast cameras, which researchers at the IJS developed together with American colleagues.

The teachings of Slovenian scholars, who in the past centuries marked Slovenian physics, were in steady mutual exchange with westerner advancements. Today's experimental physics without the use of vacuum technique is practically unimaginable. We particularly emphasized the achievements of professors Sirk, Peterlin, Osredkar, Blinc and Strnad as the leaders of others. Nor did we avoid the Slovenian philosophical physicists like Dolenc or Detela, who in their works touched the "voids". We included the interesting thinking about vacuum as a limit. The use of Toynbee-Kuhn-Južnič's method for illustrating the development of vacuum techniques is also a novelty. When we explained the use of vacuum in industrial production, we even included the history of vacuum technology for the preparation of dishes and cleaning. The book contains a very comprehensive list of archival documents collected for many years in domestic and foreign archives. Access to the Vatican archives and others in Europe and America was facilitated by the University of Oklahoma, which also financially supported this research. The book is very conscientious about the Slovenian and English naturalistic technical terminology. The technical terminology was updated to fit this kind of work. We use a juicy language, so the book is well readable. Sometimes we go into a detailed description of some of the peripheral events, which gives the narrative extra authenticity and consequently makes it no less professional. If we limit ourselves to a factual description of professional achievements, the book would have lost much of its readability. The narrative unveils many attractions. So, for example, we find that in 1894, chemist Swaty put into operation a Maribor grinding plant and that Kager metal workshop from 1737 was the predecessor of today's Maribor Foundry. We also learned that the Ljubljana watchmaker and electro-mechanic Josip Geba installed his phone in the fire monitor tower of Ljubljana castle at the premises of the Ljubljana Fire Brigade on 14 January 1882. Interestingly, the famous prof. Simon Šubic then boldly doubted this novelty. The book also tells us that Jožef Murko's money loans, mediated by the law student, later military priest Milan Panajotović, pushed Tesla into depts which ruined Tesla's studies in Graz. We deal with the achievements of Nikola Tesla, especially those related to the vacuum technique. Tesla was "appropriated" by Slovenes because he spent in Maribor a shorter period after his unfinished studying in Graz.

We also learn from the book that in the 18th century, the "Réaumur Degrees" was used to measure the temperature, and the line unit (approximately 2.2 mm) was used for measuring the length, while with the eudiometer (which measures the change in the volume of gases during the chemical reaction) our academic ancestors measured the "goodness" of the air. This research is a wonderful walk through the history of science in the space of today's Slovenia and beyond. We can only be grateful to those who made a lot of effort in preparing the book because they enriched us for many insights that we would not be able to grasp otherwise.

We studied the works of the Carniolans including the astronomer Hallerstein's successesin Beijing (2002), Jurij Vega's scientific, military and masonry activity (2003) and the extraordinary success of Vega's professor of astronomical-nautical sciences Gabriel Gruber (2004). At the International Year of Astronomy, we completed another trilogy on the history of exact sciences in Slovenia with Astronomy (Didakta, Radovljica, 2008), Physics, and Mathematics (2009). We are interested in the connections between the Jesuits of Ljubljana and their wealthy patrons, the Auersperg princes, Erberg barons and the scientific ideas of the Jesuit student Janez Vajkard Valvasor. We published over one thousand scientific works in Slovenia, China, Japan, Hungary, Croatia, Poland, Serbia, Russia, England, Austria, Germany, Italy, Australia, Spain, Catalonia, and the USA. In 2006, we discovered the second edition of Copernicus' book, which for centuries lay forgotten in Ljubljana.

After the first two parts of the History of Vacuum Research and Vacuum Techniques with collected publications from 1993-2004 and 2005-2010, the third part of the trilogy was finally available with all their English translations included. That book contained eight chapters: (1) Introduction to research and concept of vacuum; (2) Reflections on the voids among Slovenes once and today; (3) Experiments in vacuum for the first time; (4) Vacuum pumps as standard experimental tools for enlightenment; (5)

Vacuum becomes part of the electrical industry; (6) vacuum for modern Slovenes; (7) Vacuum Philosophy; (8) The leading Slovenian vacuum researchers.

Hopefully, the third part will not lag much behind his predecessors. The stories of third book were mostly published between 2011 and 2016 in Vakuumist, the newspaper of the Society for Vacuum Technology of Slovenia, the Journal of Vacuum Science, Technique and Technologies, Vacuum Metallurgy, Thin Films, Surfaces and Plasma physics. The versatility of Vakuumist editors dr. Peter Panjan and dr. Miha Čekada, the President of DVTS dr. Janez Kovač and the reviewer Monika Jenko was decisive. For this edition, we sorted our published articles into a convenient timetable, interconnected them, and tried to conceive them so that the reader receives the impression of the desired integrity of the events and their connection with the modern everyday life. We dedicated the third book to the 250th anniversary of the birth of the vacuum balloonist Kraškovič with his pioneering achievements in aviation, as well as in the field of vacuum technology. They still delight us today.

We proudly described the life and work of the first Slovenian vacuum researcher, Janez Vajkard Auersperg, and his Ljubljana disciple Janez Vajkard Valvasor. We detailed the teenage years of a poly-historian Valvasor, described his teachers and important scholars who participated in the research, especially their books published in the field of technical sciences. We especially emphasized the most important Jesuits of Ljubljana in networks of Janez Vajkard Prince Auersperg, who completed his basic education in Ljubljana and continued his studies in Germany and then in Italy. We presented the work of his teacher Ferdinand Montegnana, who also studied in Italy. Further advances of the Slovenian share in the research of early steamships were conducted under the leadership of the Jesuit Gruber. We also extensively described the work of Rudjer Bošković, who characterized his physics with a description of the vacuum and visited Ljubljana at least on three occasions. We described the operation of Kobencl's Carniolan-Gorizia family with a special emphasis on their cooperation and friendship with Bošković and the collection of books on vacuum techniques and the establishment of private libraries. All this and much more was achieved by the penultimate generation of Kobencl led by the Brussels-appointed Minister for the Habsburg Netherlands, Janez Karl Filip Kobencl. His first-rate Brussels library with technical-vacuum manuals and the Janez Karl Filipe Kobencl's collection of paintings paved the success of his pursuits in the line of Freemasonic freethinkers of the then Europe, whose interests were close to the vacuum, especially after the ballooning of Freemasons Montgolfier. Janez Karl Filip Kobencl did not read his books about the vacuum as his secretaries read and commented the novelties for him. We described his actions and failures at a time when good and timely information increasingly conditioned his correct economic interventions in the vacuum and other technologies of today's Belgium and Luxembourg, which Ljubljana native Kobencl managed for a decade and more under the name of the Habsburg Netherlands. We described in detail the first three decades of experiments with vacuum techniques in the newly established higher education physics and mathematical cabinet of Ljubljana. As the first in historiography we used Michael Peternel's partial description of the initial collection of devices of Bernard Ferdinand Erberg, compiled a quarter of millennia ago, commissioned by Gabriel Gruber in 1768, updated and signed by Anton Ambschell in 1779 and 1785 with lists of new purchases between March 1781 and March 1782. We thus emphasized the role of the Carniolan Society for Agriculture and Useful Arts in the financial covering of the cost of vacuum pumps and other purchases. From the dynamics of procurement of modern vacuum technology and related devices for experiments and from their maintenance, we learned all about the prevailing scientific tendencies or orientations of the holders of the then Ljubljana teaching chairs of physics and mathematics.

We described the beginnings of the use of vacuum technologies in the Slovenian space at the Jožef Stefan Institute and at the Society for Vacuum Technology of Slovenia, which was a co-founder of the Yugoslav Vacuum Society and (together with France, the United States, Spain, the United Kingdom, Germany, Belgium, Japan, Sweden and the Netherlands) of the International Association for Vacuum Science and Applications - IOVST in 1958 and of today's IUVSTA named on 8th December

1962. The main areas of IUVSTA are: the Applied Area Science (ASS), Phase Boundary with Biological Material (BI), Electronic Materials (EM), Nanotechnology (NM), Plasma Science (PST), Surface Engineering (SE), Surface Science (SS), thin films (TF), and vacuum science and technology (VST).

The development of vacuum and vacuum techniques provides a historical overview of the operation of Slovenian scientists and their collaboration with top scientists in the 17th and 18th centuries. It shows contemporary excellent equipment with the research infrastructure and scientific literature collected by the then scientists in several private libraries. This monograph is of fundamental importance for the further development of the field of history of science and technology and is important for the presentation of Slovenian scientific achievements in the domestic and international space, as well as for the dissemination of new scientific knowledge and scientific culture.

The vacuum has always been the central concept of mathematical-technical sciences, and it has since been a puzzle of philosophers and theologians. The modern astrophysical theories are full of vacuum, just like most of their predecessors. Years ago, my undergraduate and postgraduate professor Andrej Ule said: "For me, there is still a question, the vacuum is the absence of - what? Once we know how to respond, we really will know something. Until then, we have only assumptions." The vacuum is nothing in its own way, and somehow it seems empty. At the same time, however, the vacuum remains a relatively popular puzzle of the last millennia, while its usefulness is sufficiently recent, quite clear and of utmost value. Just over ten generations separate us from the first barometer that has emerged as a surprise outside the circle of Galileo's students and especially among the Jesuits: although it was not clear what is in it, it became obvious how useful and even funny can be that supposed zero matter in a vacuum. For two centuries, a useful vacuum was limited to scientific meters and gauges. Therefore, it may not have been so ennobling in the eyes of the Chinese Emperor as other European novelties, which were largely brought to him by Hallerstein from the sunny sides of Alpine mountains of Carniola. The vacuum technology has indeed worked out in steam engines, where the lowered pressure of vacuum was turned into an overpressure. Then, with the improved glass technology, the electrical engineering suddenly gave birth of electrical discharges turned in the cathode-ray tubes' electronics, which in the following decades developed tools for quantum-mechanical discoveries ranging from the electron and X-rays to accelerators. On the other hand, this emptied tube became the foundation of modern lighting, storages of food, productions of new materials, nanotechnologies and the entertainment industry from television onwards. A century ago, people became aware that mercury from the barometers was unhealthy dangerous and recently the empty vacuum was removed even from the most of modern displays. Only in bulbs this congestion of vacuumed zero is still almost untouched, since only the light bulb remains like that of Edison's for century and a half, probably just because Edison was such a genius himself. Also, the vacuum increasingly protects our food. Above all, vacuum somehow searches for and finds many new areas of application. It is nothing, but it should not be given for nothing or even to despair.

2 Reflections on Emptiness among Slovenes Once and Today

Contrary to modern economic problems with always stronger doubts about the ability of Slovenes, the areas inhabited with Slovenes used to be active part of the scientific pursuits in past centuries. If the perspectives are not the best today, it was not so in the previous centuries. The past inhabitants under the southern slopes of the Alps were not far behind their neighbors who today earn much more than the Slovenian economy permits. Once the inhabitants of modern Slovenia even surpassed their neighbors. The merits of Slovenian ancestors seem to be hidden, especially because many of them are somehow inadvertently declared as foreigners. With their gradually lost democratic elections after the Spring of the Nations, in the aftermath of the year 1848, one of the worst brain drains damaged these southern Alpine neighborhoods, worse than those of Črtomir, Protestant, Jesuit Gruber, the emigrations of the poor to America in 19th century or in modern days. In the spirits of political struggles whose first victim is always the truth, the noble elite of territory settled by Slovenians was suddenly declared as foreign. This unreasonable proclamation then became even more silly when applied to the ancestors of Slovenian political opponents, and thus the Slovenes not only remained without their nobility, but even without the scholars of the past centuries, which can be much more painful. This book serves its purpose also by re-proclaiming the former inhabitants within the boundaries of modern Slovenia as Slovenians, since they are not guilty of anything even if their great grandchildren were subsequently expelled as the Slovenian "ethnic national enemy".

The national colors are only one side of the present work, by no means the most relevant. Much more fresh wind brings the search for legitimacy of the development of vacuum technologies as a model for the development of all sorts of sciences. The penetration of scientific and technical innovations into the space between the Adriatic, the Alps and Pannonia, their acceptance and their feedback return effect, especially focused on Slovenian western and northern neighbours, is already well and thoroughly studied in this book, so that it can be used for the development model of all sciences as concisely described in the concluding chapters as a Južnič-Kuhn-Toynbee model.

3 No Experimental Tools for Vacuum

3.1 Vacuum: Concept Development

The issue of vacuum was important in ancient and medieval philosophy. In last four centuries, the technology of vacuum developed from the limited laboratory interest to a strong research and technological tool for nanotechnologies. In modern theories, the vacuum takes basic role. Therefore, the new millennium is surely an opportunity to see the way out from the questions: "What the hell we are missing inside the vacuum?"

3.1.1 The Vacuum in Antiquity - Introduction

The modern name of the empty is derived from Latin and not from the Greek "kenon (κενός)", although the roots of modern terms in science are mostly Greek. The reason for the exception may be in the wrong sound of the Greek word or in the prevailing rejection of the existence of a vacuum in ancient Greece.[1] Above all, there might be a very simple ignorance in the background, since many early practical vacuum explorers in the 17th century did not know Greek language well enough.

3.1.2 Aristotle

Aristotle's teacher Plato defended the existence of invisibly small atoms without describing the vacuum between them, contrary to Democritus or Epicure. The Platonists had a vacuum for the element of disorder, which the great Demiurge (δημιουργός dēmiourgos) did not use in his organization of nature.[2] It should therefore be a possible but non-existent element. A similar approach was used by the Jesuits later in their disputes against the vacuum in the barometer. The omnipotent Demiurge of Jesuits was certainly able to create the vacuum, but did he bother to do it?

Aristotle denied the existence of an empty vacuum,[3] much like his teacher Plato and before them Parmenides. The properties of the moving body and the properties of the medium influenced the speed of movement in Aristotle's system. In the same environment the body with a greater "force of motion" achieved its working space faster on its way through the substance, which allowed it to increase speed. In an empty substance, there is no resistance of the media agent. Therefore, in emptiness, all bodies should move equally fast regardless of the "force of motion"; but this did not seem clever to Aristotle. That is why he rejected the emptiness, which does not resist the movement, as he saw the possibility of infinitely high speed in it. He designed four basic elements with the natural direction of movement upwards or downwards, depending on their density. Unfortunately, in a void, the poor philosopher did not find a point of reference, according to which he could define the difference in the direction of motion.[4] So, his strange hostile vacuum rebuffed him on that side. He criticized the defenders of the empty including Leucippus, Democritus, Eleatics Melissos of Samos (Μέλισσος ὁ Σάμιος), Pythagoreans, and the Pythagorean from Croton (Crotone) in South Italian Calabria Xuthus alias Bouthus.[5] Later, the physical and philosophical atomists of the 19th and 20th centuries cited primarily Democritus and Leucippus.

Peripatetic from the Jesuit schools declared the vacuum to be a contradiction by itself. So, it sounded especially to them in their medieval Latin; they baptized vacuum as the locatum sine loco, which was certainly deeply illogical. The modernized Galileo's Italian physicists preferred Italian language in Florentine court to avoid such a language conflict which was severely dissected by Valeriano Magni with the title of his work "Locus sine locato" in 1647. This was supported by Galileo, who likewise loved to distort the thoughts of the great teacher Aristotle. Such semantic games were never alien in the histories related to vacuum with the English language light-weight attached to the light of optics included. The language which we use determines our perceptions: the best way to stay objective is to use several different languages.

3.1.3 Ancient Researchers after Aristotle

The physicist Strato of Lampsacus lived between 340 and 270 BC in Aristotle's Athens, where he listened to Aristotle's peripatetic lectures in Lycée. He described a process for obtaining a vacuum; contrary to Aristotle, he ignored the assumption of two types of vacuum. Heron of Alexandria, a contemporary of Jesus Christ nearby somewhat in eastern side, focused on the engineering scholarship. He made a "steam turbine" for sputtering the water vapor in the temples. He followed Aristotelians to assume that there was no empty space in nature. Nevertheless, in two parts of his "Pneumatics (Πνευματικά)", Heron has practically and theoretically proved that a vacuum can be created in closed containers; human products should be subject to different laws than the products of (God's) nature.

Around the year 1300, the term "horror vacui" began to scare common folks. At the same time, Aristotle's active role of the media in the motions aroused serious concerns in Paris and Oxford in the fourteenth century.[6]

3.2 Early Thinking about Empty among Slovenes

3.2.1 Empress's Thin Films

The westernized peripatetic ideas about vacuum and their criticism quickly penetrated in the areas inhabited by Slovenes. Not just ideas: even the practices of producing new substances and thin films soon became common among the wealthy on the southern sunny slopes of the Alps. The empress Barbara of Celje was the very best of them all. As an able pioneering researcher of new materials, she begins our story with her wit, while the other excellences of her gender will end it about thousand pages further. Between them, most of our subjects are men.

Herman of Carinthia opened the door into Mid-European minds for Eastern wisdom's expansion, but many centuries passed before folks knocked on them. The locals were much too busy by keeping themselves alive. No times for contemplations. Enters Barbara. Wealthy. Adorned in public. Backbit in shadows. Herman's doors of knowledge opened widely for her grace never to close again.

No matter what's ones' opinion about her husband, Melania Trump seems to be the last among Slovenian-raised rulers. This is the story about the first ones named Anna (1380/88-21. 5. 1416) and her sister Barbara (1392-11 July 1451) of Celje (Cilli), who ruled six centuries before Melania. The reader is to decide which one was better.

All three chicks were the natives of Lower Styria where they grew up. The first two were a stepdaughter and daughter of the ambitious upstart Hermann II count of Celje (1365-1435), but they soon surpassed him as the girls with their own strong minds, as well as with their own powerful courts.
Slovenia never had a king of its own, but that same land certainly nursed a handful of successful queens, empresses, or great governesses even if Slovenia not really looks like the feminist or Amazons' country. Why?

Because of the total lack of their own kings, the Slovenians borrowed the Hungarian one Matthias Hunjady Corvinus transformed into Slovenian king Matjaž. The king Matjaž is supposedly residing in a Carinthia Peca Mountain with his huge beard growing around the hills in Archimedean spirals while he is waiting for his new opportunity to save his Slovenes (again). Matthias helped his brother to kill Barbara's nephew Ulrich while Ulrich became the very last representative of Barbara's Celje house. Matthias and Celje princes were sworn enemies, but they both became the leading heroes of Slovenian glorified faked past. There was nothing Slovenian in Matthias except that he successfully fought against his contemporary Habsburgian ruler which makes Matthias a kind of local oppositional leader. His Slovenian fake story is typically domestic for Balkan, just like the one of the heroic prince-king Marko (Mrnjačević) whose two younger brothers Andrijaš and Dmitar migrated to serve under Barbara's husband in 1394, while Marko remained the Turkish vassal.

[6] Asimov, 1978, 22; Podolny, 1986, 23; Sparnaay, 1992, 14.

The centres of knowledge change. They pick up one place for a while, get exhausted, and transfer their networks to the places which seemed very barbarous just a moment before. The spreading of science is a kind of democratic process although no contemporaneous literati were ever aware of that because they imagined that their central position in erudite networks might be eternal. It proved not to be.

The Styrian settlement of Celje was such a centre once despite of Piccolomini's critiques. The settlement nursed its privileged position for about a century, and, suddenly, its times were over.

3.2.1.1 Celje (Cilli)

The thousand inhabitants of the market Celje were glad when their rulers moved from the huge southeast upper castle to their more comfortable lower city castle. They used to tell each other in secret when their rulers were not at sight: "Well, if I had to pay so much taxes to make my landlords fat, it is still much better to have them around to watch their bellies grow, than to let them stay in that hill castle and see them once a month." The folks laughed: "You are certainly right. Now that we have our wealthy landlords here among us, they are much more like ones of us." Some suspicious guys did not agree very well: "Take care about your wives and daughters, my dear fellows. The sexual appetites of those landlords of ours has no limit, and now that they live so close to us, there is no obstacle to stop their megalomaniac wishes… Many of your offspring might have the blue noble blood suddenly!"

For the teenager kids and especially daughters of the landlord Herman II of Celje the funny busy market called Celje was far more interesting than the huge boring castle on the nearby hill. All eight of them kids used to play together despite of the dozen years of difference between their ages. There were no apparent competitions between Herman's legitimate, illegitimate, or adopted offspring. The oldest Frederik was the leader of them all including two kids named Anna, two Hermans, Elizabet, Ludvik, and the youngest Barbara. They loved to play on the banks of Savinja river and in the old metallurgical areas nearby. Barbara was always finding the exciting pieces of minerals in the pebbles she passionately collected: "Look at those! What a nice pebble. The sun shines through every detail of its structures to make its surface shine like a thousand broken mirrors. What might be the composition of the pebble which makes it so strange? Which compounds does it contain? Please help me to carry all those pebbles back home to our Celje castle and I will ask our father's personal astrologer to perform some alchemistic analysis of the structure of the pebbles. It is quite possible that some precious metals are involved! Those Celje jewellers could put the pieces of those pebbles in my diadem for my birthday present, don't you think?" Frederik laughed, while he was getting used to the extravagancies of his little sister.

Anna lost her father very early while her mother Anna quickly remarried with Ulrich duke of Teck in Swabia.[7] Barbara of Celje was born around 1392 in Celje as the youngest daughter of Hermann II, Count of Celje, and Countess Anna of Schaumburg. Barbara's own mother Anna von Schaunberg died when Barbara was only four years old. Anna von Schaunberg's widowed husband Herman II refused to remarry because Anna gave birth to quite enough of his offspring and he preferred to keep as many mistresses as possible. The feminine mother's hand was missed in the developing worldviews of his children which had huge consequences on their future sexual affairs. Barbara was sad as an orphan: "Dear Anna, you've lost your father as a little kid, and I also have lost my mother before I barely knew her. You are luckier because our father Herman adopted you and he is like a real father to you. Me, I have no such luck. There will be no mother to adopt me, that's out of a question, just look at the eyes of our father Herman and you will easily find up why. He's not going to find us a stepmother, that for sure. I'm orphaned, eternally orphaned, deprived of my mother's care, and you are not you are naughty happy princess of Poland!" "Do not get upset, Barbara. You are not orphaned at all. If you wish, I could play you mother for a while. It's going to be fun."

[7] Ulrich duke of Teck died in 1432 (Lukanc, Maja. 2016. Ana Celjska. Celje: Pokrajinski muzej, 12); http://genealogy.euweb.cz/baden/baden1.html

3.2.1.2 Krakow

The new century proved to be the turning point for both youngsters. The widowed Polish king needed Anna's royal genes to legitimize his rule. The widowed Hungarian-Croatian king needed the support of Barbara's father to get the Bohemian and imperial crown. Both grooms were a quarter of century older than their brides, but the call of politics was far stronger than any love scruples even if the Polish king did not find Anna particularly attractive. In 1401 both girls left the banks of Savinja river forever. Their dog Urs was extremely sad because he was not allowed to accompany his beloved girls to their new destination. With his deep instinct, Urs even felt that he would not be very welcomed in his hut by the lower Celje castle without his girls and their mutual care. To avoid his dangerous destiny, Urs wandered around the market Celje a lot. Urs was barking sadly while the Celje counts Herman II and his eldest son Frederik accompanied their Anna and Barbara to Krakow. The summer was there while they rode northwards some 750 kilometers in a huge wealthy caravan. They passed Graz and Vienna with prolonged stays and had a lot of fun. They arrived in Krakow on July 16, 1401. By the city gate the Polish king Władysław II Jagiełło and his suiters greeted them. Władysław II Jagiełło used to be in eternal quarrel with Barbara's fiancé the Croatian-Hungarian king Sigismund of Luxemburg who tried to get Polish throne previously. Władysław was therefore not extremely happy to greet the fiancé of his former sworn enemy Sigismund together with his own fiancé,[8] but the Celje counts had their own interests in playing the intermediate to soften the royal quarrel.

In any case, Barbara urged her fiancé Sigismund of Luxemburg to marry her as soon as possible because Barbara just couldn't stand the fact that Anna outrun her in marriage and children productions. In November 1405, probably in Croatian city of Krapina of the possessions of Barbara's father,[9] still teenager Barbara married Sigismund of Luxembourg, the king of Hungary with Croatia included. Soon afterwards she was crowned as the queen of Hungary. The grandchildren were not Barbara and Anna's primary concern although Barbara's only grandson Ladislaus V the Posthumous later became the famous medicine-man as king of Croatia-Hungary and Bohemia, adorned with his court astrologer Georg von Peuerbach[10] who predicted almost all royal motions. Barbara's favourite was George Gemistus[11] with his heretical Platonist teachings based in Florence, but she preferred to get her astrological predictions based on then popular twelve houses fundament from Johannes Gmunden and Heinrich von Langenstein.

Anna went to Krakow monastery of the nuns of Poor Clares (Order of Saint Clare) of St. Andrew the Apostle to learn Polish language for the needs of her traveling fiancée,[12] while Barbara was also educated as the traveling fiancée of her eternally journeyling royal groom. Barbara and Anna's grooms decided to travel as much as possible.

Among Barbara and Anna's Krakow classmates in Krakow academy recently restored by Anna's husband was John Cantius[13] who studied the impetus of Parisian university erudite Johannes Buridanus.[14] They liked to have their joint long discussions although they were not all on the same frequency with their thoughts.

Their mutual teacher Andrew Wezyk nicknamed Serpens[15] sometimes joined their debates in their Krakow headquarters. Serpens got his bachelors' degree in Prague in 1397 and he upgraded it with his masters' degree of arts in Krakow in 1402. Serpens was the clear total supporter of Averroes and Buridanus, while Serpens later became a Dominican. Andrew the Serpens was much more on the side of John Cantius during their quarrels, but he was clever enough not to oppose the almighty queens: "Do not get upset, my dear queens. John Cantius has his right path and you also have your own. John Cantius'

future is the future of the truth-seeker, just like mine. We are researchers. The destiny of a queen is to rule, not to research. The knowledge is the highest goal of them all, but John Cantius' path to the wisdom is not the only one. You, the queens, you have your own pursuits to knowledge you need, but please be so kind to provide the material support for us, the poor lovers of sciences."

Barbara and Anna understood well Andrew Wezyk Serpens' applications and tried to help. The great opportunity soon emerged. The young queens clearly realized that Barbara and Anna's Krakow knowhow was based on the optical teachings of the Paduan University student the Pole Witelo.[16] What the Krakow university needed was a strong well equipped group of professional astronomers who could support Barbara and Anna's thirst for astrological knowledge based on their model Herman of Carinthia. That was not all they needed, also the observational astronomy should be practiced just like elsewhere in Europe, and as they recently heard, also in Ulugh Beg's Samarkand and in China. The young ladies made a great plan to search for the wealthy local individuals why would be willing to pay the price which was by no means the small one. Barbara and Anna courted well the wealthy Krakow burgher Jan Stobner[17] who graduated in Prague in 1379. "Dear Jan Stobner, we are so pleased to have you in Krakow. So much pleased indeed. There's a way to make your name known for eternity, for all Krakow citizens to come. Please be so kind and put some money on disposal of our new planned university chair where the secrets of astronomy and astrology will be hunted in mathematical ways!" Jan Stobner's soul quickly melted on those nice female sounds, and the accompanying secret additional unspoken beautiful girl's promises: "My honourable ladies! A man must be made of stone not to fulfil the demands of such a nice bunch of young queens as you are. All I have is on your disposal, my ladies, all my possession down to the last coin in my treasuries. We will make the Krakow mathematical stars-researchers the best worldwide, I assure you!" Jan was so pleased with the funny girls and their astrological pursuits that he donated his own funds for the Krakow Chair of Astronomy and Mathematics. In 1402/1405 his generosity founded the prestigious chair which soon attracted many scholars,[18] just like Anna and Barbara planned.

Besides astronomy, there was another important point that made Krakow university extremely attractive as Barbara and Anna soon figured out. Together with many others of their social class, Barbara and Anna initially supported the ideas of Jan Hus. They sounded nice, just like all ideas do, until they are endorsed by the massive movements of all kinds of folks. The nice sounds of Hus's ideas suddenly become something very subversive which questioned the very fundament of their queens' networks and that aspect of Hus' teaching soon confused and feared Barbara and Anna. The great new advantage of Leipzig and Krakow university was its ability to oppose Jan Hus' novelties which attracted Hus' learned enemies from Prague who were not quite fans of Hus' priorities put on Czech language. One of the best of them was Andrew of Kokorzyn.[19] He studied in Prague to get his bachelor's in 1399 and masters in 1402 under the dean of faculty of arts and the rector in 1402-1403 named Jan Hus.[20] In 1402-1403 with final split on 18 January 1409 John Wycliffe' teaching in Hus' interpretation alienated literati who were not Czechs from Prague Charles' university. Hus was not Andrew's favourite, therefore Andrew left for Krakow where he became the dean of the faculty of arts. He lectured about physics in 1406-1407 and commented Aristotle's achievements.[21] Andrew shared his feelings with Piotr Wysz Radoliński Leszczyc[22] who studied in Prague and Padua. From 1391 Piotr served as a chancellor in the court of the queen, and he was appointed Bishop of Krakow on 4 December 1392, soon after Barbara's birth. In 1397 he co-founded the Department of Theology in Krakow and served as the first chancellor of the university established in 1364. Stanisław of

Skarbimierz[23] was the rector after him as he took over his ruling rector's stick in 1400, while their colleague Paweł Włodkowic[24] also used to be a distinguished scholar, jurist and rector.

Barbara's best Krakow astrologer was the sympathy of her royal mother and friend of Anna's stepson the Bohemian and Hungarian-Croatian king Władysław III.[25] His name was Henricus Bohemus[26] which indicated that he was a kind of Czech. Henricus Bohemus was experienced in geomancy but he got imprisoned for several years in Krakow as a Hussite and possessor of necromantic books. The similar evil destiny dogged Barbara's Krakow acquaintance Gajusz as well.[27]

3.2.1.3 Prague

Their Krakow drunken scholarly funny parties all to soon ended for Barbara and she had to leave Anna. Barbara had to join her royal groom and to settle in the appropriate queen's castles of the nearby kingdoms of Bohemia and Hungarian North Croatia. Once settled in the golden Prague, Barbara quickly learned Czech language and became much more popular in locals Czech speaking networks[28] compared to her husband who was widely seen as the traitor of Hus in the Council of Constance. Barbara did not support the extreme Taborite wing of Hussite parties, but she was able to find supporters among the more moderate Hussite folks of their Utraquists' party. Barbara preferred to use her royal Bohemian or Hungarian-Croatian titles to the imperial ones which she never consumed;[29] that choice also made her popular in the areas where she was the crowned queen. She was no Hus' traitor herself, she spoke Czech language fluently, and most of all, she was beautiful. All that combined with her wealthy occult researches provided the basis for her extreme popularity among the common folks as well as among the leaders in Prague. Her alchemistic networks in golden Prague became the prototype fulfilled two centuries later in the Prague court of Rudolf II with his employees including Tycho Brahe and Johannes Kepler.

Barbara missed Anna a lot. To fill up Anna's place in Barbara's heart, Barbara's main Prague female friend became the widow of her husband's stepbrother Vaclav of Luxemburg.[30] Her name was Sophia von Bayern-Munich[31] and she was a decade and half Barbara's elder. Sophia also supported Jan Hus together with her husband until the pope banned Hus in 1410 to prove to all the infidels that there might be something subversive in Hus' seemingly good-mannered teachings. Sophia used to accompany Barbara during her travels as the somewhat special member of Barbara's court.

Barbara's alchemistic research lead her interests into the investigations of all kinds of substance including the gunpowder used for warfare and especially deeply misused by her husband's sworn enemy Žižka's Hussites. Barbara's favourite warfare expert used to be Konrad Kyeser[32] who inscribed his nicely illustrated Belli Fortis full of alchemistic and magic visions to misguide the enemy in 1402-1405. Konrad wrote down his ideas during his spare times when Barbara's husband exiled him from Prague to his hometown of Bavarian Eichstätt north of Munich and Ingolstadt. Kyeser's novelties failed to distinguish himself during Barbara's husband and father's lost battle of Nicopolis in 1396 which made Kyeser quite unpopular,[33] but Barbara still admired his prophecies.

Barbara was the youngest daughter of Herman II of Celje and Anna of Schaunberg, and Anna was her

adopted sister as well as her second cousin, daughter of Herman II' first cousin Wilhelm who died in 1392.[34] As all other Herman's children, Barbara too had a very special place in his scheme for the rise of the Celje dynasty. However, her father probably never imagined she would go all the way to become the wife of the Sigismund of Luxembourg, the Holy Roman Emperor. Herman II of Celje most likely started to put together the pieces of the marriage puzzles of his children soon after his king's defeat against the Ottomans in the Battle of Nicopolis (Никопол, 1396), which could have ended tragically for king Sigismund without help of the Count of Celje. Numerous proofs of gratitude (estates and honours) followed, all leading to the marriage between Barbara of Celje and the widowed King of Hungary Sigismund of Luxembourg in 1405. Thus, the Counts of Celje won an "ambassador" and promoter of their interests in the very top ranks as Barbara wholeheartedly supported her husband's graciousness towards his father-in-law and the Counts of Celje in general. Among other favours, Herman II, Barbara, her daughter, and Frederik II of Celje were admitted to the Order of the Dragon, and the Counts of Celje became the Princes of the Holy Roman Empire.

Barbara liked Prague and she even more loved the success she had in the city as the admired queen. She liked to talk to the folks in Czech language which was somewhat linked to the Slavic Slovenian dialects which she used back in her good old Celje headquarters. Almost no other ruling member of the nobility spoke Czech so good, often, and with pride like Barbara and her late father-in-law Karl IV did. The locals knew very well how to admire that nice Barbara's habit although she never really got used to the fact that the Czech called her Barbora instead of her preferred name Barbara which she liked so much: "Well, every Sun has its sunspots, and I will become Borbora if I must", she told the locals jokingly. She even began to drink the local beer after the pope recently allowed the breweries outside the monasteries and the Bohemian beer slowly penetrated to Bavarian headquarters.

Nothing was so fancy in Barbara's Prague as the incomparable clock-astrolabe which soon became her favourite destination. The oldest part of the Prague Charles University hosted Barbara's beloved Orloj, the mechanical clock-astrolabe and astronomical dial. In 1410 Vaclav (Wenceslas) IV's imperial clockmaker Mikuláš of Kadaň (Kadaně) made the famous clock on design of Jan Šindel.[35] Jan Šindel studied philosophy in Prague for his M.A. in arts. After his lecturing in local parish school he became the teacher of mathematics in Vienna where he also studied medicine and learned a lot from Viennese astronomers and astrologers. Vienna was not his favourite, therefore he returned to Prague as a professor of mathematics and astronomy in Prague Charles' university, the Doctor of medicine, and rector in 1410. Jan earned even more as the personal astrologer of Vaclav and Vaclav's stepbrother Barbara's husband Sigismund. Barbara soon found that Jan Šindel is far the best of all experts whom she could afford: "Sir Jan Šindel, you are the very best literati in all our Golden Prague. I have learned some twelve houses astrology back in Krakow in my times, but your knowledge is far deeper, as I'm fully aware. Please share with me some of it but be aware that I have no patience for all those boring mathematical formulas. Therefore, please let me go straight to the point where I would be able to cast my own horoscopes, if you please." Jan Šindel was respectful but at the same time he also liked to be real: "My highly respected queen my ruler of all rulers! I love your Czech spellings and I also respect the careful support you are giving to the moderate part of our Hussite movement, which is Czech in its fundament, as you well know. I must disappoint you. There is no royal way into mathematics, just as my Alexandrian model Euclid liked to tell to his royal patron Ptolemy I Soter (Πτολεμαῖος Σωτήρ). If you want to know the stuff, you must learn it with all the efforts and sweats involved, if you'll be so kind to excuse me for that strong unroyal expression. No sweet road into the mathematics, just the sweat one. On the other point, it's nice to hear that you want to cast your own horoscopes. Nice, but also frightening in the same time. I must admit that point, as I can see the consequences very clearly. That's very unfair concurrence because you will deprive of the jobs all of us, the poor astrologers. The God invented

[35] Jan Šindel (Jan Ondřejův, Iohannes Andreae dictus Schindel, Joannes de Prague, abt. 1370 Hradec Králové-1455/1457).

astrology to enable us astronomers to earn some extra money, because otherwise we could get hungry. And now, you are up to deprive us of that funny profitable job?” Jan Šindel drank a glass of royal wine to clean his throat because he noticed that Barbara evidently got upset: “I’m just kidding, my beloved queen. We will make the greatest astrologer and horoscope caster out of yourself because you are far the cleverest queen we ever had here in Prague. Considering the royal path into that funny mathematics, we’ll invent something which will spare your time, with God’s fairy help. If I’ve got the right idea, your nice shortcut into mathematics will fly on the wings of astrolabes and equatorium…”

Together with Barbara’s networks, Jan Šindel initially supported his namesake Jan Hus, but Jan Šindel never abandoned his Roman Christian faith while he preferred science over the religious disputes. The Hussite wars forced Jan Šindel to abandon Prague for the safer Olomouc. In 1423-1437 in Nuremberg he worked as physician while he was also acting as the personal physician of Barbara’s husband the emperor Sigismund after 1432. After Sigismund’s death Jan Šindel became the dean of Vyšehrad Chapter (Vyšehradská kapitula) in Prague where he was in frequent touch with Barbara who lived in the nearby royal castle of Mělník. In his later years from 1445 to 1447 Jan Šindel friendly corresponded with the future pope Pius II, the humanist Enea Silvio Bartolomeo Piccolomini. Enea was the enemy of Barbara’s nephew Ulrich in the times when Barbara also got alienated from Ulrich over their diverse disputes on the heritage of imperial crown. Jan Šindel used to tell Enea: “Your critique of Barbara is far to sharp. She might be from that funny Celje heritage of mixed Bosnian Germans, but her personality is far better than those of her relatives. It is true that she uses her sex-appeal to achieve her political goals, but she also used her charms to advance sciences which is not bad at all. She is not a whore, far from that, she just loves to play with the masculine hearts while she keeps her lovers on distance from her bed, at least in most occasions. The sciences she promotes are certainly not the best of them all because she prefers the prophecies of astrology and the alchemy of new materials, but at least she is up to some mathematical kind of knowledge. Therefore, she needs to be distinguished from most of the other crowned heads whose owners never read anything except the political pamphlets. Be so kind, dear Enea, and try to reformulate your critiques of Barbara into some jokes and funny stories. I have heard that you had the unsuccessful love affair with Barbara, but that’s the destiny of all us men whom Barbara turns around her fingers with her soft promising voice all the time. Forget that, that’s a kind of hobby of Barbara and please try to see the funny side of it. She’s great and you must admit it, sooner or later.” An important Viennese humanist Piccolomini, the later Pope Pius II, convinced the future generations that the magnates of Celje relationships to humanism was relatively dull, at least if the people believe Piccolomini’s memories written from the political party opposed to Ulrich of Celje. Jan Šindel tried to be the peace messenger between Barbara and Piccolomini all the time, because Jan Šindel had wide interest in the networks of the both parties in seemingly eternal quarrels. In his younger times, Piccolomini even visited the court of Celje, but he did not create excessively high opinion about the folks there who were certainly also his political antagonists. Shortly after the year 1442 Piccolomini came to the Viennese court of Frederik III where he was crowned as the poet laureate under the auspices of the emperor's chancellor Kaspar Schlick. In 1445, the emperor sent Piccolomini to Rome, while in 1447 Piccolomini became the Bishop of Trieste. In that times his sharp words against Barbara already softened a little bit because of Jan Šindel’s frequent suggestions. Still, Piccolomini never stopped his sarcastic comments of Barbara and emperor’s repeated splits. Enea Silvio Piccolomini used to be the worst Barbara’s critic also because his voice was heard very far despite of its deeply rooted political colors. Piccolomini was certainly a top humanist and then he also became a pope. As a youngster, Piccolomini did not hesitate to pick up a girl or two of them, and he even did not try to hide those facts from the posteriorly readers in his memories. In his best days, Enea Silvio Piccolomini even tried to court the dozen years older Barbara but he was not encouraged at all which damaged his pride a lot and made him a lifelong opponent of Celje house whose peril he finally witnessed several months before he got the tiara.

Jan Šindel was aware of most of the affairs of his friend Enea, but Jan Šindel still tried to shut up or at least calm down Enea's critiques of Barbara which Jan Šindel considered to be inappropriate and harmful for the advancements of the humanistic sciences worldwide. Jan Šindel's astronomical tables were good enough even for Tycho Brahe two centuries later. Two centuries are a great space of time, which proved that Jan used to be a great observer. Despite of Jan Šindel's warnings, Barbara wanted to pave her own royal path into astronomy-astrology anyway and the astrolabe was her tool to avoid the boring difficult geometrical calculations. She wished to learn how to get at least the approximate positions of the stars with her astrolabe which became her daily companion in its golden execution of the very best Prague goldsmiths. The design of the astrolabe in use was a clear status symbol of those days, therefore Barbara got the best of the best of it.

Besides the stars, Barbara additionally also needed to find out the positions of planets while the Sun and the Moon figured as something special in both networks. While the astrolabe covered the daily needs for the approximative position of the stars, she also needed an instrument to show her the yearly approximative positions of planets, which was based on far more sophisticated geometrical theories and did not really figure as the status symbol because the most of folks found it to hard and complicated to use. The instrument used to show to Barbara the approximative positions of planets over years was certainly much more complicate than her astrolabe. Barbara's astrolabe was the best appreciated within a single day while the information which astrolabe provided repeated after one year. Barbara's instrument which show her the approximative positions of planets over years was called with its Latin name equatorium in contrast to the Ancient Greek-based name of the astrolabe. The Latin was used because the equatoria gained their popularity much after astrolabes. The Latin name equatorium meant something like a correction because of the bettering that she needed to make to convert a planet's mean position to its actual position. On Barbara's demand Jan Šindel developed sophisticated equatorium called albion which not only predicted the positions of planets, Sun and Moon, but also estimated their mutual eclipses. Barbara demanded: "Dear Jan Šindel, you might be right in your Euclidian statement that there is no royal way into mathematics, but we could invent the queens' path into it anyway. My nice planetarium is one of the components of that path designed by the secret Byzantine Antikythera mechanism and somewhat bettered with the new contemporary ideas of Campanus of Novara.[36] As you know very well, I'm also in the possession of the excellent astrolabe which I'm very proud of. The astrolabe is not enough for me even if I have the possession of the best of them worldwide because my instrument is based on the Al-Andalus work of the Moorish al-Zarqālī.[37] My astrolabe gives me the very good approximations of the motions of stars, but I also need to know my astrological relations to the planets. Therefore, I need the equatorium, precisely the English abbot Richard of Wallingford's (1292–1336) form of it nicknamed albion which not only predicts the positions of planets, Sun, and Moon, but also predicts their mutual eclipses. I need the predictions of eclipses very urgently because I want to astonish the folks by telling them all about the eclipses they could expect in future. Not just the eclipses of Sun and very usable eclipses of Moon while the blockings of Moon are frequent enough to earn me the admiration of folks worldwide. I also need the accurate predictions of the eclipses of planets which will provide the good opinions about my knowhow among learned literati. Therefore, be so kind sir Jan Šindel and provide the nice albion for me as soon as possible." Jan Šindel was honoured with that royal demand, but he was also somewhat worried in the same times: "My dear noble queen, that will be the honour for me. I'm good and I learned a lot in my times, but the albion is clearly an extremely sophisticated instrument for me to manufacture it, as well as for you to use it. I know, you are the most clever of all queens of the world and you will be able to learn how to use my abion in no time. There is the other problem which I certainly must report to you. Me alone, I'm still not good enough to make the best of all abions which is the one you need. Please allow me to form the team of designers for that royal task. I will like to share my ideas with in the collaboration with the Viennese

[36] Campanus of Novara (1220-1296).
[37] Abū Isḥāq Ibrāhīm ibn Yaḥyā al-Naqqāsh al-Zarqālluh, Al-Zarkali, Ibn Zarqala, Arzachel, or Arsechieles (1029-1087).

professor astronomer Johannes z Gmundenu[38] who is now a kind of Viennese replacement of Sorbonne educated Heinrich von Langenstein.[39] As you certainly heard of, Heinrich von Langenstein began to lecture on theology and astronomy in Viennese university in 1384, soon after it was established in 1365 and I had learned a lot from him there. As you know very well, Heinrich von Langenstein was instrumental in development of astronomical tower of Viennese university where he served as the University rector in 1393/94 in the times when I was also lecturing in Vienna. Gmunden was his best student although Gmunden got his masters after Heinrich von Langenstein's death in 1406 and substantially immediately became the very first Viennese professional lecturer of mathematic, physics, and astronomical sciences in German speaking areas[40] in the times when I already left for Prague. Me and Gmunden now work in different universities and in different cities. He is more like a German, and I'm more like a Czech. But the science knows no national borders of such kinds, so we kept ourselves in friendly mutual relations. That's why I will be very glad if I could employ Gmunden as I need his help to design the very best abion for you." Barbara smiled with her best deeply promising royal smiles: "It's up to you, my dear Jan Šindel. I'm the queen Barbara and I assure you that I like them both, Gmunden and Langenstein, although I'm not as frequent guest or visitor in Vienna as I would like to be. I was there much more often before my unhappy quarrels with my own daughter and my Habsburg son-in-law, as you certainly had heard about."

Jan Šindel was glad and he immediately put himself into sophisticated networks to fulfil the queen's demands. Despite of Barbara's recent reservations because of her sad family quarrels, her Celje relatives were traditionally very generous to the Viennese literati especially after they bought the expensive building in the prestigious part of Vienna. Gmunden's work was soon advanced in the hands of Georg von Peuerbach who was promoted in Vienna after Gmunden's death. Peuerbach studied in Vienna before he journeyed to Italy to meet Bianchini and Nicholas of Cusa. Soon after Barbara's death no later than 1453 Peuerbach came back to Vienna. In the following year Peuerbach became the court astronomer of Hungarian king Ladislaus V Posthumous, whom Barbara's nephew Ulrich of Celje supported with wealthy hands. Thus, the Celje magnates also greatly supported Peuerbach and the Viennese astronomy-astrology as the network of literati. Despite of Ulrich's generosity and the wide astrological-alchemical interests of the empress Barbara, the magnates of Celje relationships to humanism was relatively shallow because Herman and Ulrich just used the humanism for his political goals and not vice versa. Many professional humanists found their views somewhat frustrating. But that is the reality: only rare rulers really love wisdom more than power like Ulugh Beg who was two years Barbara's younger eastern ruler or later emperor Rudolf II. Both lost their power to their closest relatives who knew better all the dangers around the position of vulnerable king philosopher.

3.2.1.4 Barbara's Worldwide Networks

The only real convinced humanist among the Celje magnates and maybe even among all the crowned heads of her times was Barbara. The golden Prague was the pearl of them all, but Barbara also figured as the Hungarian-Croatian queen and had to spend the considerable portion of her times in those Hungarian-Croatian headquarters which were suffering more and more under the Turkish threats and frequent raids of the Muslim or pretended Muslims from the nearby southern areas. The Hungarians tried to form some university level studies in Hungary proper or in Bratislava, but the fear of the Muslims' raids made all those projects somewhat short-lived until about twelve decades after Barbara's death. Compared to Krakow, Vienna, or Prague full of the traveling humanistic literati like Piccolomini, Barbara's Hungarian-Croatian erudite circle was far less advanced. Her courtiers were even surpassed by the later astrological reigning court of the brother of the murderer of Barbara's nephew, Matthias Hunjady Corvinus.[41] Just the young Hungarian-Croatian generations were slightly better

with the Barbara's decade and a half younger acquaintance John Vitéz de Zredna[42] who studied among others in Vienna to become the prominent politically oriented archbishop, mathematician, astrologer and astronomer. For his scientific pursuits, John Vitéz de Zredna used his deep connections with Pier Paolo Vergerio the Elder[43] whom he met in the court of Barbara's husband together with Veronika Deseniška. John Vitéz de Zredna became the tutor of the future Hungarian king Matthias Hunjady Corvinus whose brother Ladislaus Hunyadi (László) killed Barbara's nephew Ulrich in Beograd. The astrologer and physician of John Vitéz de Zredna and of the king Matthias Hunjady Corvinus used to be Regiomontanus' collaborator Polish canon Martin Ilkuš-Olkusz.[44] Martin Ilkuš-Olkusz manufactured the instruments for the Krakow university and after Barbara's death he lectured on astrology in Bratislava based short-lived *Universitas Istropolitana* as the colleague of Regiomontanus, Vitéz, and Galeotto Marzio.[45]

The newly popular astrology as the mathematical part of astronomy was a segment of the spread of humanist tendencies of Francesco Petrarca,[46] and his friend-correspondent Giovanni Boccaccio's *Il Decamerone* written in 1349-1353. Both of those were Barbara's favourite writers although she had some trouble with their Italian language which was not her best and no translations were at hand quickly enough.

Arnold de Villa Nova[47] published his *Nova opera medica et chirurgica* which pleased Barbara a lot. There was a lot of alchemy there which she deeply wanted to master. Still, Barbara remained the fan of Franciscans and their medical alchemy including her favorite experimental-technological-philosophical basis of the South Italian Franciscan Paul of Taranto of Apulia alias pseudo-Geber. Paul wrote incognito his Aristotelian alchemy almost a century before Barbara's birth, but Paul's deep insights into the alchemical Ars magna secrets made his works readable for many generations to come. The Krakow education of the Franciscan order of Poor Clares (Order of Saint Clare) finally brought fruits in Barbara's mind because the Saint Clare nuns proved to be her straightforward connection with Franciscan alchemy. The Franciscan William Ockham's[48] Quaestiones[49] were among Barbara's bests although Barbara as the fulltime mystic did not always follow the limits of Ockham's razor. William Ockham has taught in Oxford and London, the places Barbara never visited in person. His new logic was separated from the ancient Aristotle while his understandings connected the time and the movement.[50]

Figure 3-1: Barbara's Samobor castle.

Barbara loved to play the Goddess in her mystic alchemic-astrological ways which brought her very close to Al-Biţrūjī-Alpetragius.[51] Barbara fully approved Al-Biţrūjī-Alpetragius' statement that people can solve supernatural questions, which was at odds with the opinion of Aristotle, Averroes, and other scholars, although Al-Biţrūjī was a member of

[49] Under number 221 of Glonar's catalogue of the monastery of Stična books (J.Glonar, Iz stare stiške knjižnice. In: *Glasnik Muzejskega Društva za Slovenijo* (1937), 125).
[50] Donnini, 2004, 124.
[51] Al-Biţrūjī-Alpetragius (Nur al-Din ibn Ishaq Al-Biţrūjī, * Morocco; † around 1204 Sevilla (J. Ziegler et all, *In C. Plinii De naturali historia librum secundum commentarius*, Basileae 1531, 29, 32-35)).

the Spanish school of Aristotle's fans.[52] Barbara certainly felt as the queen of all queens. She was sure that she could solve supernatural questions. Her way into astronomy was certainly a kind of different from Al-Biţrūjī's because the study of astronomy took Al-Biţrūjī by surprise after he saw some antagonism between Aristotle and Ptolemaic teachings. Al-Biţrūjī asked himself why Ptolemaic teachings objected to Aristotle's philosophical attempts, although Al-Biţrūjī essentially took all the parameters of the Almagest.[53] Of course, Al-Biţrūjī quoted the Quran (Koran) to support his ideas. The clever Al-Biţrūjī was aware that all those astronomical novelties were not at Muhammad's disposal when he dictated his Quran (Koran). The Quran (Koran) does not mention the eccentric spheres, but Al-Biţrūjī felt rightfully that they cannot be ignored. Based on the Quran Al-Biţrūjī rejected all spheres except seven of them. He equipped his manuscript with illustrative drawings, but they were not too close to the later N. Frischlin's pictures.[54] Copernicus mentioned Al-Biţrūjī's work on the order of the planets, but Regiomontanus refused Al-Biţrūjī because of the supposed Al-Biţrūjī's erroneous interpretations. Al-Biţrūjī took over the computations of Levi ben Gerson († 1344) and other Jewish astronomers. Al-Biţrūjī and his fellow Moorish genius al-Zarqālī were among five Muslims whom Copernicus quoted[55] after Barbara's death, which was also a kind of consequence of Barbara's promotions of Al-Biţrūjī's merits.

As the reigning queen, Barbara was not a great fan of Roger Bacon's anarchistic in-jailed worldviews of the marvelous poverty needed for the sound scholarship, but she liked Bacon's practical astrology needed for the contemporary judicial predictions. In fact, that was the same kind of astrology which Barbara practiced. Roger Bacon's praised optics as a new academic discipline to be introduced in curricula on behalf of his informal teacher Robert Grosseteste of Franciscan Oxford school. Roger Bacon's promotion of optics as the new research field was the very first one in the row

Figure 3-2: Barbara's Samobor castle from inside: what was left of her lab?

which later promoted magnetism, electricity, heat phenomena, chemistry, and so on. Barbara with whole heart supported the claims like that, while her support was in some senses much more important that the opinions of the professional literati because Barbara was their wealthy patron as well as the renowned practitioner of the alchemy-astrology focused on new materials. Barbara was not interested just in experimental part of Bacon's optics, but she wished to learn more about the nature of light for her transmutations of metals where the colors of the changeable products played the prominent rule. Barbara's favorite therefore became the Franciscan Thomas of York with his studies of the nature of light.[56] In her practical astronomical-astrological pursuits Barbara needed optics, but the somewhat occult forces of magnetism were even more important to her. Roger Bacon's teacher and friend was his fellow French Franciscan Pietro di Maricourt[57] who announced the *Epistula de magnete* of eternal impact in 1269.[58] Barbara liked the stuff and used huge magnets in her Samobor alchemic lab in tight connection with enterprises in her nearby mines of copper. Her unconventional behavior earned her a dangerous funny title of black queen, probably connected with her widow's black suits or with her alchemical dark arts. The vampire legends of her black witchcraft whereabouts never ceased to

be told in Samobor, nearby castle of Medvedgrad, and the nearest city of Zagreb.[59]

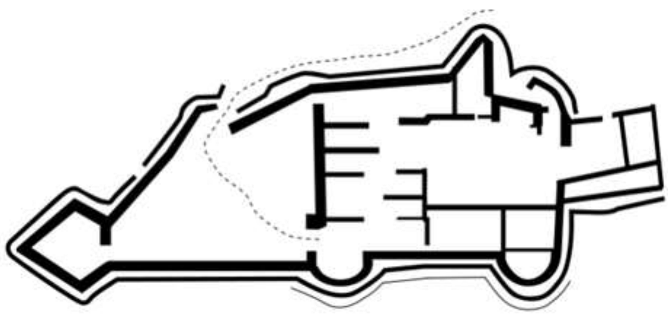

Figure 3-3: The layout of Barbara's Samobor castle with the lab in the cellar.

Barbara's fascination was the motion which she observed in her touchable Ars magna transmutations as well as in the remote motions of the heavenly bodies. Her inspirations were again the Franciscans, among them Richard of Mediavilla.[60] In his theory published in *Calculatores* he set the new perspective of physics. Richard of Mediavilla argued against the fundamental principles of Aristotle's physics-metaphysics.[61] The English Franciscan of Augustinian orientation Roger Marston[62] was a Parisian student of the Franciscan optician John Peckham (1230-1292) who died as the Archbishop of Canterbury. In 1328 the later Archbishop of Canterbury secular priest of Oxford Merton college Thomas Bradwardine (c. 1300-1349) wrote his *Tractatus proportionum, seu de proportionibus velocitatum in motibus* where he studied the relationship between resistance and speed. He rejected Aristotle with his own rate of velocity as the ratio of an exponential increase of the driving force to resistance as the first Western author to introduce the exponential growth in the equation of physics. Bradwardine's velocities vary arithmetically, while the ratios of force to resistance vary geometrically. Bradwardine's theory of isoperimetric figures (having equal perimeters) was widely used.[63] The Englishman Gualterius Burlaeus of Oxford and Parisian professorships wrote about the theory of impetus in his comments of Aristotle's physics published later in 1589.[64] Gualterius Burlaeus used the arguments of logic in the newly advanced fields of physics. He was among the first who focused Barbara alchemistic interests on the newly bettered theory of heat. Gualterius Burlaeus used logical argument to promote the idea of the singular substance of heat in contrast to the opposite idea of the separate substances used to describe the coldness and the warmness. Gualterius Burlaeus claimed that contrary forms, such as hot and cold, belong to the same ultimate species because logically things equidistant from an extreme are of the same species. By Aristotle Gualterius Burlaeus argued that if a cooled body is immediately reheated, at some instant, *B*, preceding the first instant when the body is cold, *A*, it will have a degree of heat, and at some instant, *C*, succeeding *A*, it will have a degree of cold, both of which degrees will be formally equidistant from maximum heat and thus of the same species. This argument also reflects contemporary debates over the latitude of forms, the intensive range of possible degrees that a quality may possess. It also reflects the first and last instants of change. Gualterius Burlaeus might have been Ockham's classmate and the student of John Duns Scotus in Oxford as a part of the once huge British Franciscan scientific networks which Barbara admired so much. As a lecturer in Paris Gualterius Burlaeus quarreled with the Oxford lecturer Ockham over their different forms of peripatetic physics.

Barbara was equally interested in North Italian contributions to the knowledge which suited her. As the reigning queen and the wife of the emperor, she certainly supported the fans of her husband called Ghibellines in Apennine Peninsula. The employee of Emperor's fans Ghibellines Guido Bonatti[65] first studied law, until he was converted with the mathematical muse. He became a professor of mathematics at the University of Bologna, occasionally even in Paris. Bonatti became one of the leading astrologers and astronomers of his time,

he was perhaps even the most important astrologer of 13th century.[66] He correctly predicted a victory of the Ghibellines' army of Siena. Federico Guido Novello helped the defeat of the Florentine Guelphs in the Battle of Montaperti in 1260, after the victorious Ghibellines occupied the city. Barbara supposed that they maybe won precisely because the Bonatti's prophecy uplifted their extra courage, as Bonatti himself opposed Guelphs and the Pope, which was certainly also the option of Barbara's husband, the emperor. At the court of Emperor Frederik II Bonatti collaborated with the polyglot famous for his Arabic-Hebrew-Greek knowledge named Michael Scotus,[67] even if Bonatti did not quote Scotus' adaptation of Johannes de Sacrobosco's[68] *Tractatus de Spraera*. Bonatti's reputation grew after his success in providing a proper prophecy for the count Guido de Montferrato (Montefeltro) whom Pope Martin IV together with French allies besieged in the city of Forli. On 1 May 1282 Montferrato escaped and won the unequal battle despite numerous wounds. Bonatti derived his knowhow from the Arabic knowledge and added his own experiences. He was the first to explain the importance of astrology. He carefully considered the positions of planets, their impact on the Earth, conjunctions, and the like.[69] Bonatti died in a Franciscan monastery. Despite the long-standing conflicts with Franciscan, as an old man he dressed himself in a Franciscan habit which pleased Barbara a lot.

The other Barbara's window towards the eastern wisdom was Pietro D'Abano[70] who had embarked on a longer visit to Constantinople (Istanbul) where he read the works of Galen, Averroes, and Avicenna in original. After returning home he acquired a reputation as a translator. He has taught medicine, philosophy and astrology at the University of Paris, and since 1306 in Padua as the main supporter of Aristotle and a friend a few years elder Marco Polo.[71] Both won Barbara's sympathies although both spent their times in prisons and D'Abano even died there as the captive of Inquisition because of his magic.

The North-Italian Humanists' frames were soon upgraded from eastern sources which Barbara preferred because of her Bosnian networks of Barbara's Celje grandmother Katarina Kotromanović and Bogomil's networks related to Hus which Barbara's husband sadly destroyed during his bloody crusade.[72] Katarina Kotromanović was the first cousin of Bosnian-Serbian king Tvrko I Kotromanović who was closely related to the legendary prince-king Marko (Mrnjačević). Despite of turbulent times of wars they used to have the first-hand knowledges of Byzantine and Muslim sciences which expanded mostly through land routes of those times. Barbara was interested in philosophical aspects of the alchemistic research in India, and she was as well extremely upset with the very first supposed perpetuum mobile. The device was constructed in India by Bhaskara II[73] for more religious aspects, while the Arabic traders transferred that wonder to Barbara's nearby European headquarters as the very first of its kind. In Europe, Bhaskara's tool lost its religious-philosophical meaning which was essential for its whereabouts in India. The Christians with Barbara included had no way to understand the Indic religious philosophy, therefore they just employed the technical aspect of the imported item, as they did with so many other knowhows which they imported from India including the infinitesimal calculus. The great figure of Barbara's contemporary new eastern knowhows was Madhava[74] with his major work of 1403 in Sanskrit based on his Indian predecessors of Kerala school. Madhava was not that much interested in gnomons, while he preferred the mathematical part of astronomy called astrology with the disputed rotation of planets included. He bettered the calculation of the number pi, the series expansions, as well as the integrals. Those mathematical details were not the ones which Barbara liked and understood the best, but she certainly enjoyed each part of Indian patina in her astrological predictions.

Further east, the orphaned kid of Muslim origin was captured by Chinese-Han Ming rulers after his father was killed. Under his eunuch name Zheng He,[75] the orphan led the prolonged expeditions to South Seas and Americas. Most important of those Easterners was Barbara's peer, the grandson of Timur (Tamerlane) called the sultan Ulugh Beg.[76] After his lost Nicopolis battle Barbara's husband and father considered Tamerlane as a kind of ally since Tamerlane had stopped the Ottomans for a while after Tamerlane defeated and captured Bayezid I in Ankara (Angora) in 1402. Therefore, the Catholic Europeans also supported Tamerlane's grandson and student Ulugh Beg, but Ulugh Beg proved to be entirely casted from the different kind of mould as a kind of Plato's philosopher-ruler, actually the best of that kind which ever existed although Barbara resembled Ulugh Beg in her somewhat narrower networks. Barbara never had a real observatory of her own, although she always wished to erect it. Ulugh Beg established his observatory in Samarkand with his excellent employees including al-Kāshī[77] and Ulugh Beg's student reformer of Aristotelian astronomy-mechanics al-Qushji.[78] The enterprise worked nice like a kind of heavenly clock, but those heavenly knowhow were never designed to work in the frames of the naughty evil greedy humans. The great Ulugh Beg's observatory worked just until Ulugh Beg's own son found the earth more promising compared to his murdered father's stars a year and half before Barbara's own death.

Barbara and her networks of humanists Platonists soon rediscovered their Balkan-Byzantium headquarters with the distant Ulugh Beg included as soon as the Byzantines began to migrate westwards from their collapsing Greek-speaking traps threated by the Turkish Ottoman Muslims. Many of those eastern refuges joined Barbara courts long before the most famous of those Byzantine lecturers from Constantinople named Johann Agyropolus[79] fled to Italy to teach Leonardo da Vinci and the Medici about Vitruvius' art. As all his erudite Byzantine fellows, Agyropolus knew the ancient Greek language which enabled him to translate a lot of Aristotle's Physics inter alia. Agyropolus got his additional doctorate in Padua during a diplomatic mission, lectured in Padua until 1471, in Florence and then in Rome. Barbara liked the golden colors of the Byzantine whereabouts and tried to get as many Byzantine refuges in her court as possible to learn more about their alchemy.

3.2.1.5 Principal-Counts of Celje, not to Speak about their Veronica of Desenić

Barbara liked to use her royal status to advance the Counts of Celje. With Sigismund, she founded the Order of the Dragon[80] just before Christmas on 13 December 1408. The funny order brought together the closest imperial confidants and the biggest, wealthiest, and the most important European rulers of the time. Barbara and her daughter were the only females of that famous elite order, whose members included Herman II and Frederik II of Celje. Barbara was proud: "That Order of the Dragon of ours is the real achievement! Very good indeed also because it seems that I'm the only real woman in charge there besides my lovely daughter Elizabeth.[81] Never mind the feminism, but that membership of mine makes me more than equal of all the men involved including my husband, father, brother Fredrik, and brother-in-law Nikolaj II Gorjanski (Garai). My grandmother's relative the Serbian despot poet Stefan Lazarević or the would-be Transylvanian ruler are somewhat obsolete founding members of our order, but there is still something great in that funny Order of the Dragon of ours. The insignia of the Holy Grail are there and everything I need for my astrological-alchemical work."

In 1411 Barbara of Celje's fiancée Sigismund was elected as the king of Romans (*Romanorum Regina*, *Römisch-deutscher König*), as the ruler in-waiting of the Holy Roman Empire of German nation, and he was crowned King of German nation in Aachen on 8 November 1414. He exercised the right to have his wife crowned alongside him, and Barbara of Celje thus became Queen of Romans (*Römisch-deutscher*

Königin), which legitimately placed her at the very summit of her contemporary state authorities. The Germany of those times had not much in common with German national or linguistic boundaries because it also included Denmark as well as North Italy, Croatian Istria, Carniola, Styria, Bohemia, and other Roman or Slavic lands.

Figure 3-4: Barbara in Constance as noted by Ulrich of Richenthal

The coronation to the Queen of Romans (*Römisch-deutscher Königin*) in Aachen (1414) and Barbara's glorious accompanying of her husband to the Council of Constance (1415) which was not Jan Hus' favourite were the highlights of Barbara's marriage to Sigismund. The king Sigismund soon became somewhat upset: "My dear Barbara, you have no right to cry over the destiny of that crazy prophet Jan Hus. The prophets are only good for ordinary folks, but we are the rulers and we do not mess with those ugly smelling folks. You are going much too far with the astrology and alchemy of your beautiful face." The king's warnings were in vain because Barbara was just too much extravagant for her time and place. It was never quite certain what Barbara did in Constance (Konstanz). The chronicler Constance native Ulrich of Richenthal[82] mentioned her only rudimentarily, because Barbara did not participate in the Council. Church matters were a kind of menaced men's affairs, and like the other queens who came to Konstanz during the Council, Sigismund's Barbara was not allowed to attend the meetings. But Barbara had her own ways to promote herself.

The rumors about Barbara's crazy alchemistic-astrological ways soon proved to be much to harmful for her husband's networks. Their honeymoons were accelerated into strange orbits followed by their break-up because of Barbara's destructive midnight shouting and Constance escapades. Very quickly there was their royal couple's first (informal) separation in 1419 while Hus's fans led by former chamberlain of Barbara's friend Sophia of Bavaria named Jan Žižka[83] fought down Barbara's poor husband in every battle of theirs. Žižka promoted the use of gunpowder and his newly invented movable field artillery which soon made the Bohemians prominent in artillery business until the industrialization of that field in Napoleonic wars. Barbara's model the Franciscan Roger Bacon was among the first to promote gunpowder in Europe, but Barbara certainly disliked Žižka's making any profit of that discovery. Barbara commented to her furious royal husband: "My favourite Chinese alchemist Wei Boyang[84] described the substances needed to produce the gunpowder mixtures long ago. He was the descendant of a long tradition of Chinese magicians-alchemists while he composed the earliest book on alchemy and the first document on chemical composition of gunpowder worldwide nearly thirteen centuries ago. You are stupid my dear husband, it was not clever to let that one-eyed Žižka of Cyclops' sort to be the first to use such an old invention in Christian European lands. If you ever bother to listen to your wife's alchemistic advices, you could have been much earlier user of gunpowder provided in my alchemy labs." But the facts went beyond Barbara's possible interferences: the combative Czechs Taborites of Žižka's camp were a kind of peoples' army like the French revolutionaries four centuries later and no crowned head was their match.

[82] Ulrich of Richenthal (died about 1438).

[84] Wei Boyang (Wei Po Yang, 魏伯陽).

Figure 3-5: Barbara during the Constance Council as noted in the chronicle of Ulrich of Richenthal.

The split of the royal couple was short-lived because Barbara was just too clever to be left behind and the king certainly needed her charm, as well as her alchemy and astrology. Barbara of Celje was an important representative of the Counts of Celje in the highest circles of European nobility. Barbara used to tell her husband: "Well, honey, it really seems that you dislike my midnight hysterical shouting, which I deeply regret. The shouting is not all I know. My connections with Krakow Polish court of my beloved sister Anna are deep and therefore please employ me into your diplomatic service. I will become more than useful there, you can bet on that." Sigismund looked at her eyes after another night during which he was unable to get any sleep at all and at the first sight wished to call Barbara names because of all that night suffering she has provided for him. He just began to shout, but he suddenly realized that Barbara might have a right point, at least in that diplomatic whereabouts. Soon Barbara played a major role in establishing peace between the Polish crown and the Teutonic Knights, and in the alliance between the Grand Duchy of Lithuania and the kingdoms of Poland and Hungary because the Polish kingdom was the biggest European country of those turbulent times.

Barbara of Celje was one of the most progressive and free-thinking women of the age. She was a genial diplomat; she knew how to make money, spoke several languages, and argued in favour of new artistic and social developments. Most of all she had a strong interest in astrology and alchemy. She was often depicted negatively during her life and later by jealous historians, but more recent studies are presenting a more objective image of her.

Barbara was the secret shadow behind the disgusting legend about her unwanted sister-in-law Veronika Deseniška. She tried to learn some Veronika's alchemistic secrets, but Barbara didn't have the guts to oppose her father Herman's will. Barbara was also very instrumental to smoot her father's seizure of Ortenburg's heritage. Ulrich duke of Teck[85] was the brother of Margaret Teck.[86] Their parents were Frederik IV Duke of Teck[87] and the countess Anna. Margaret Teck, the wife of Otto's son Frederik III of Ortenburg[88] helped a lot to advance Barbara's networks. Margaret Teck's only son died young and her marriage with Frederik of Ortenburg proved to be the unhappy.[89] On April 28, 1418 in Leibnitz[90] a nice lady Margaret Teck, the relative of Anna's stepfather Ulrich of Teck, gave the other half of poisoned apple to her unsuspecting husband Frederik III who became the very last Count Ortenburg a moment later. After that sad family quarrel Margaret's relatives, the mighty Counts of Celje, took over Gottscheerland and other former Ortenburg property in 1420. Barbara's father count Herman II of Celje, the son of Herman I,[91] inherited the Ortenburg areas with Gottscheerland included by their mutual contract of 1377 and sly counts of Celje kept the property until their abrupt princely end in 1456. Margaret's other unlucky brother was the patriarch of Aquileia Ludwig II/IV duke of Teck who lost his Aquileia lands to the Venetians and resettled to Herman's Celje court, which was a great blow to her pride. But she was strong and powerful,

[91] Herman I of Celje (1333-1385).

and she did not hesitate to offer her poisoned half of an apple to her husband to enable her Celje relatives to get his heritage. The son-in-law of Herman II of Celje became her relative the future emperor Sigismund of Luxemburg,[92] and that was the power of all powers. Sigmund betrayed the Czech priest Jan Hus to bring a war and with it the new settlers from disturbed Bohemia to her lands all along the Upper Kolpa river basin. The Thuringians might also provide new migrants for her Upper Kolpa areas. Her dreams have come true. The land of hers was fertile and inhabited, although her husband was now buried and the former Ortenburg areas passed to her relative Herman II of Celje.[93]

Before Barbara's birth, in 1388 Count Herman II of Celje engaged and around the year 1405 married his eldest son Frederik II († 1454) with Elizabeth Frankopan, the daughter of Stjepan I Frankopan of Modruš and of the island of Krk. Stjepan was a prince between 1360 and 1390, and he married Katarina, the daughter of Franjo Carrara, master of the Paduan Town.[94] The diligent bride Elizabeth Frankopan did not hesitate too much and quickly gave birth to Ulrich II. She brought the dowry of the prosperous Bakar town harbor to Frederik II because the Counts of Celje dreamed about their accession to the seaside. The city of Bakar became the principal harbor for the smuggling trade from the central Carniola because before the collapse of Zriny-Frankopan Conspiracy (1670) the town of Bakar was not subordinated to the regulations of Habsburg imperial customs officials. Herman II prosperously married his daughter Barbara of Celje[95] with the king Sigismund I of Luxemburg.[96] Herman became Croatian, Slavonian, and Dalmatian Ban.[97] Herman also found the suitable high positioned husbands for his daughters Elizabeth and Anna: Elizabeth got the bed of the fifteen years old teenaged count Majnard Henrik of Gorica (Gorizia, * 1385; † 1426) in the year 1400, and somewhat later Anna married the palatine Nikolaj II Gorjanski whose sister was a second wife of the prince Nikola IV Frankopan.[98] Around the year 1445 Herman's granddaughter Margaret († 1480), the daughter of Herman III, married for the second time and her choice was Vladislav († 1463), the son of the Silesian Duke Cieszynsko-Glogovski. Herman II used to say to his family members: "Well, I've done all possible to make you a great family. Probably I cheated a little bit and ruined a person or two on that way to the top, but that's eventually the price you had to pay if you want to become a real successful ruler. Our focus of expansion is now shifting from the northwest to the southeast, from the overcrowded networks of Renaissance rulers to the Balkans. To succeed, we need the Byzantine collapse, which is at hand, but we need even more to defeat the Ottomans, which we failed to do altogether as far. With Ottomans behind our necks, all our efforts will perish into the ashes. Remember, you have to produce as much sons as possible and accomplish all military, diplomatic, astrologist, or alchemistic networks to keep those dangerous Ottomans out of Balkans."

On February 28, 1420 in Bratislava (Pressburg) the Emperor Sigmund confirmed the Ortenburg heritage to Sigmund's father-in-law Herman II of Celje, and in Celje the prolonged visitor Patriarch Ludwig gave to Henrik all former Ortenburg-Aquileian feuds including Gottscheerland.[99] In that way the Celje counts became the strongest family dynasty in the Slovenian National area and Frederik used his opportunity to accommodate his illegal nest above the settlement of Gottschee. In the year 1421 Herman II gave to his son Frederik II a part of his possessions including the manors of Teničnjak, Samobor, Mehovo, Novo Mesto, and Kostanjevica with Frederik's independent court in Gurckfeld (Krško) town on the banks of Sava river. Frederik II liked to hunt in Gottscheerland forests, and he finally hunted up his best trophy named Veronika there as the very best pearl from the royal court. From around the year 1415 he lived separately from his legal wife of the mighty Frankopan family, which

was somewhat dangerous move. In the year 1422 or a year later his Frankopan wife was found dead in her castle Krapina, but the cause of her misfortune was never clearly put at the limelight. It is quite possible that Herman II's persistent tries to bring together the unhappy married couple on bad terms caused the disaster. Herman II wanted to get as many grandsons as possible and the only reliable grandson Ulrich was not enough for him. Herman had heard about so many families which got extinct in their male lines that he became somewhat paranoiac with some astrological predictions suggesting the similar ill fate to his own family. After 1422 Frederik II was not without guilty merits when he erected the castle above Gottschee for his new fiancée Veronika von Desenice.[100] Frederik wanted Veronika of Desenice and Margaret Teck was happy to provide for the new couple her previous build castle of Fridrichstein above Gottschee for their love nest just before Margaret died. Their residence was called Friedrichstein ever since. The jovial widower Frederik II neglected his father and Emperor's opposition with dangerous anger included and married Veronika in the year 1424/25. Her family could originate in the castle Desinić across Sotla in Croatia near Slovenian Podčetrtek, but she is rather unknown in Croatian genealogy. She came from one of Hungarian-Croatian castles while she had some connections with Silesia. She was of noble origin, but she certainly had much lower rank compared with the counts of Celje. Right after her marriage before the summer of 1425 the circumstances sharpened so much that Frederik II asked for asylum in the republic of Venice. On June 25, 1425, Venetian doge and senate refused Frederik's petition because they quarrelled with Habsburgs just as Herman II did and did not want to abandon Herman's support. The Venetians also rejected Frederik's offer to buy his properties from Elizabeth's dowry on January 7, 1424, probably because they considered the deal dangerous as Frederik had no real practical control above those estates. Frankopans recaptured those manors, but the Emperor asked them to return them back in the year of Herman's death of 1435.[101] In 1425 the Venetians took over the secular power of Aquileia Patriarch Ludwig II in Friuli and Istria, therefore humiliated Ludwig asked for his relative Herman's help, resettled to Celje, and confirmed the feuds which Herman inherited from Ortenburgs. Ludwig prolonged visit in Celje stimulated the Celje landlords' appetite to develop their own bishopric in Celje, but in all real comparisons the settlement of Celje was far too small to compete with Vienna or similar metropolis.

The Emperor Sigismund hired the Danish King Erik VII who visited Hungary between June and August 1424, to give the judgment about possible Frederik's involvement in his wife's murder case. Frederik did not seem to be much upset, but next year the emperor captured Frederik and handed him over to his father-in-law, Herman. Barbara was silent: "The family quarrel is the worst of them all. I understand my brother, he wants that bitch Veronika so much after he discovered her in my court. That relation could bring Herman the necessary male offspring, just in case if my nephew Ulrich will get some troubles in that point. On the other hand, my crazy brother crossed the line. He expected that my father will calm down after Veronika gave birth to his grandson, but Herman just wasn't that sort of guy…"

Herman tied his unhappy son for his captured trip in a covered wagon. He closed his chained heir in the tower of Celje County castle Ostrovec, forced him to return his manors, and demolished the Friedrichstein Castle above Gottschee.

The unwanted daughter-in-law Veronika and her chambermaids hided in the ruined castle, in nearby woods, and in remote village Kunč (Kunschen, Kuntschen, Kleč) cave under the Gottscheer Horn forests east of Altlag. The ladies hided in nearby ice cave which was 10 m high, 10 m long and 20 mm wide. The air currents kept the ice in the cave almost all year round to enable the nice ladies' comfortable summer and autumn stay[102] with the cold summer beer and wine included. After Margaret Teck passed away, Veronika had nobody to relay on, so she was hiding for a while in a cave near Kunč village east of Gottschee. A century and a half later the Kunč Village had a hide and a half. The village probable got its name from its inhabitants named Künig who

[102] Thanks to dr. Miha Čekada for a note.

had the neighbours with the family name Mauser there in the year 1574.

The cave was horizontal and tall, but the ladies from her court were not extremely happy there with only dirty peasants for their company. Veronika felt like her youthful beauty is passing away in vain, so she tried to make a short visit to her domestic folks on Croatian side. The reckless Veronika secretly but not cautiously enough visited the castle of Frederik II in Petovia near her reputed home castle of Desinić. The sly Herman traced her out and closed her to Ostrovo (Ostrovec) Tower where her husband Frederik already waited for the better days. She was judged in Celje but the able layer saved her from the witchcraft accusations which could be the very first one in that area. Herman eventually had no legal rightful position to bring the noble Veronika to the court in Celje.[103] Veronika cried: "By murdering me you will also murder your own grandson. Your other grandson Ulrich probably doesn't like my son, his eighteen-years younger kid stepbrother as his future competitor, but that doesn't change the fact that you are going to ruin your own dynasty!"

Veronika's father-in-law Herman II who did not want to be her father-in-law was quick to prove that Veronika's beauty was really vanishing. "Hello, Veronika, the damned choice of my crazy vicious son! Please be so kind and leave my Frederik alone, there are plenty of other noble lovers you could play with," Herman demanded. Veronica was proud: "My dear father-in-law, please just remember the times you were of Frederik age," and she tried to charm Herman a little bit because she did not recognize that the power is the only charm Herman really loved: "I'm blind to your charms, nice maid. Please behave yourself or you'll get drowned as you do not really know how to swim properly!" What a terrible mistake! Under her heart, Veronika was carrying Herman's grandson or more of them who could save Herman's dynastic male line. Herman did build the dynasty, but he also ruined it for the Habsburgian benefit. In fact, some of those high society folks did not care much for their grandchildren and did not cry when their heavily grabbed property passed to their related dynasties. The life and death were quick close friends of their times and they did not really care for posteriors except some more clever among them like the Habsburgs or Auerspergs. Despite of Veronica's success at the provisional unlawful court of Celje, Herman ordered two knights to drown Veronica in the bathtub on October 17, 1425, although it was a pity to get rid of such a beauty. With such a cruel act Herman excused himself of supposed guiltiness for the death of his daughter-in-law Elizabeth Frankopan in the eyes of Croatian nobility. In those times the Frankopan Prince was the only Elizabeth's brother Nikola IV[104] and Nicola could be the very hard enemy if he felt that his honor was offended.

The second Herman's son Ludwig died in the year 1417, his illegitimate son the bishop Herman died in year 1421 after the unsuccessful operation in Celje, and Herman III died in the year 1426. Solitary and full of misfortune Herman II had to release his only son Frederik before August 24, 1426 because Frederik was simply the only son Herman had left. To clear up the consequences of lengthy quarrels Frederik II went on a pilgrimage to Italy. In the same times, his and Elizabeth's only surviving son Ulrich II[105] went on a Spanish pilgrimage in the Iberian Santiago de Compostela, but Ulrich eventually forgot to arrange a good looking Celje heir with his countess Katarina Branković because all his offspring died much too early.

Veronika was buried in Braslovče, but disconsolate widower Frederik later took her bones to the monastery of Carthusian monks in Jurklošter. He prayed there on the anniversaries of her death and gave a present to the monastery of Carthusian monks in Bistra for her memory.[106] Frederik renovated the castle Friedrichstein above the settlement of Gottschee in the year 1433, but he was not looking for a new bride,[107] although several beauties tried to charm that wealthy old man. After the death of Herman II, the Emperor Sigismund of Luxemburg confirmed to his brother-in-law Frederik II the former Ortenburg feuds and raised Frederik and his son Ulrich II to the rank of Principality of Holy

Roman Empire on November 30, 1436. As Princes and Counts they were subordinated only to the Emperor himself, although the Habsburgs refused to accept all formal aspect of Celje Princes' independence and still observed Celje magnates as one of their subordinates.[108] There was almost no higher possible position available for Celje landlords, but the breakdown of Celje magnates happened all to soon two decades later.

3.2.1.6 Habsburg Shares

Barbara died in 1451, her brother Frederik died in 1454, and Frederik's son Ulrich was killed in 1456 as the very last male of his descent. A year after Ulrich's death the Gottscheerland and other possessions of Celje magnates passed over to Habsburgs because of the similar heritage contract (1443) which enabled Counts of Celje's heritage after Ortenburgs' huge possessions lost their last male descent three decades earlier. In December 1457, Ulrich's widow Countess Katarina had to give the properties of her deceased husband to the Emperor Frederik III Habsburg.[109] The Celje Princes' manors of Polland and Gottschee became the Habsburg property for next century and a half, a century after Ortenburgs gave several Polland hides as a feud to Zobelsberg nobles in 1359.[110]

The first Gottscheerland Parishes belonged to the archdeaconry of Slovenian Mark or Krajina (Carniola). The oldest parish of Ortenburg possession south of Ljubljana was Ribnica and from there they led the secular and religious government of all their south province for a long time. On September 1, 1339, the Aquileia Patriarch Bernard permitted Otto V Ortenburg (* 1292; † 1343), a son of Frederik I, to install a priest in Mooswald chapel of St. Bartholomew in the areas of today's Gottschee. On May 1, 1363 1339 the Aquileia Patriarch Ludwig II della Torre[111] in Udine permitted Otto's nephew Otto VI Ortenburg,[112] a husband of the Barbara's relative countess Anna Celjska, to suggest the priests for their superior Ribnica rector's confirmation in churches of Mooswald (Gottschee), Polland, Kostel, Ossiunitz, and (Gottschee) Rieg called Göttnitz.[113] The permit was not the document of establishment or even of erecting of those churches. In Stari Trg of Polland the church worked at least a century earlier. The parish Göttenitz (Gotenica) was established in the year 1845 and did not have a priest before the year 1786. Therefore, Ludwig II certainly meant a neighboring (Gottschee) Rieg where a priest Johannes Zink,[114] the scribe of Margareta Teck at the first place, pastured the souls already before the year 1377 as a successor of priest Melhior mentioned in the year 1375.[115] The clever Zink fathered several children,[116] but didn't have much to do with the famous Margaret's half of the apple because he died three years earlier. His supposed great-grandson Clement Zingkale was noted among the last subjects of Rieg where he cultivated the half hide in 1498.[117] Zink was strictly speaking the only Swabian settler from the original settlement whose destiny is eventually clearly documented for the future researchers. His nephew Burkard Zink[118] described his life when he escaped from his evil stepmother in 1407 to study in Ribnica school for seven years.[119] Burkard Zink left the areas before the Celje magnates took them over, but he was aware of their mighty positions.

Herman II of Celje and his grandson prince Ulrich were the only ones able to challenge the Habsburg supremacy on the ancient Argonautic Sava and Danube rivers including the Ljubljana areas. Herman wished to rule the world and to get as much as possible into his hands. He liked his friends of Teutonic Knights' Order whom he helped in their wars against Prussians in 1377. Herman II kept the famous coup of St. Grail (Graal) in his Styrian castle of Rogatec[120] but he was convinced that the amulets of his Order of Dragon could be even more powerful. His favorite rigorous Carthusian order of the Catholic Church successively established four monasteries in Slovenian Lands: in Žiče (1164), Jurklošter, Bistra (1260), and finally the Monastery of Pleterje south of Ljubljana on Herman's own orders. The people wondered why the rigorous Carthusians founded so many monasteries in the lands inhabited with Slovenes, but their goal was obvious: they knew that Herman needed them, and they hopped that Herman will help them to keep their strongholds. The clever Herman knew what the Carthusians are up to and therefore supported the Pleterje monastery not to miss his share of the divine opulence with Carthusians' monasteries now encircling Ljubljana from all sides.

Herman II of Celje urgently needed the connections with the very top networks because he wished to rule the world. In 1405, he engaged/married his daughter Barbara of Celje[121] to the future Emperor Sigmund of Luxemburg[122] elected in 1433. The naughty Barbara's brother Frederik performed some disputed love affairs in his castle above Gottschee,[123] and Barbara's nephew and final hope Ulrich on his way to the top of European politics forgot to make enough children of his own. The Italian visitors respected the mighty Celje court but dismissed their poor education with no major schools or universities founded in the area, although there was some rumour of future Bishopric of Celje. Barbara was different from the most girls of her age: powerful, wild, and on search of the secret knowledges urgently needed for her alchemical pursuits. When her dreams finally came true and she got her crowns which extended her jurisdiction even to Ljubljana and deep on the East, she was overlapped with joy. She smelled her precious alchemistic-astrological goals somewhere in the vicinity while her imperial husband was busy with his Hussite wars. When she finally found out her own Ars magna, her poor old husband died, and her power slowly vanished together with his soul. She was never able to put her foot into Ljubljana again and passed away on the eve of Gutenberg's[124] printing era borrowed from the Chinese networks which could have pleased her so much.

The Jason-Medea's Golden Fleece was all but forgotten and Barbara's relative duke of Burgundy Philip the Good established the prestigious order with that name of Golden Fleece of Jason's memory in 1430, with a sovereign usually on the top position of the order. Barbara liked the idea but as a female she was not invited to become a member, while her husband was too busy anyway. Barbara was deeply disappointed because as the full member of Dragon Order she expected to enter also other similar organizations.

Later the Spanish and Austrian branches of the Golden Fleece order gained their prestige with Habsburg rulers on the top positions of the order of Golden Fleece and Auerspergs also included on regular basis began with the first great Carniolan researcher of vacuum the prince Janez Vajkard Auersperg. The most alchemistic-astrologic of all emperors worldwide Rudolf II of Prague joined the order, and almost all emperors followed him while producing gold with their assistants' stones of wisdom in their spare times. Herman's son Frederik II of Celje married a Frankopan girl Elizabeth in unhappy coupling which Frederik ended similarly as Margaret ended her own four years earlier. The unhappy marriages sometimes bring happy offspring and Ulrich II of Celje[125] was supposed to be one of them. Barbara put all her hope for her successful Balkan politics on her young nephew Ulrich who son betrayed her hopes as the supporter of Barbara's Habsburg grandson. The new upstarting Celje

counts-princes were successful in everything except in the legitimate children-making after Herman II ceased to do that job. With the Aquileia Patriarch as their perpetual guest in Celje they also planned the seat of Bishopric there while they made no move to establish the higher education enterprises outside the church. Kostel castle was one of their favorite strategic strongholds, therefore they rebuild it and enlarged the old Oldenburg castle there. After the sad year of Herman II's death in 1435 the extremely happy Celje counts' year 1436 followed with their newly acquired title of imperial princes in their pockets. It was no surprise as the empress was the sister and aunt of both newly promoted princes, the alchemic ruler Barbara. The newly appointed prince Frederik noted that Barbara did not wear any usual black dress to commemorate their father's recent death: "What's up Barbara? I supposed you will be still in black because of our recent tragedy in the family?" Barbara felt much better in her lighter colors: "Our father died – so what? He was rather old, and you probably hated him anyway because he ordered the murder of your lovable Veronika?" Frederik was rather upset. He waited a little before he spoke in a low voice after he drank and eat his share of the meal: "Our father died – then what? Please speak more quietly, Barbara. My son Ulrich should not hear anything like that! He is already in his late twenties, but he is still a kid, a kid deeply in love with his grandfather. I do not mean much to Ulrich - his grandpa was all to him. If Ulrich anyhow happen to learn anything about your crazy statement 'our father died – then what?', Ulrich might become your sworn enemy. For my part, my heart died with Veronika. You knew her very well as she certainly was an angel. But that was a decade ago. The father was wrong, now we have just Ulrich to keep our dynasty afloat and Ulrich's firstborn George is not a very strong kid. Veronika would be a perfect mother, but it's a buried past now. I died with Veronika, but I also forgave our father, even in Veronika's name. A guy cannot live with such a hatred in his heart, not me. Our father was crazy in his pushing to the top, you are quite right about that. But, there is another side of the medal, he did all he did for us, for us who are his family…" Barbara did not agree at all: "Your son Ulrich is like a brother to me because he isn't much younger than me, a dozen years or so. Still, I cannot talk to him openly. 'Our father died – then what?' is sad but true statement. Yes, our father accumulated enormous property in his lifetime, together with the great political forces to serve his goals. Otherwise, he was a fool. He had no understanding of the symmetries of nature where a guy must be in balance with both of his dual equally strong Chinese principles of yin-yang as Marco Polo recently reported. Our father was wrong because he swore just on one half of the principle while he was accumulating all the time, and never donating much except for priests and monks. The Bogomilist Bosnian promoters are also wrong because their dualism endorses one pole as the evil one and not as the equivalent to the other. The legendary Dzou Yen[126] did better in China some eighteen centuries ago. Dzou Yen disliked our four bases while he promoted the Taoist five bases without gases involved called wu xing (wu hsing, 五行, metal, wood, water, fire, earth) combined by earthy female yin and heavenly masculine yang. On Dzou Yen's merits the king of the state Qi (Chhi) established the academy Jixia (Chi-Xia) in 318 B.C. six decades after Plato's Athens Academy. Certainly, the Chinese academy was made with somewhat different goals, because the Chinese are different compared to the European Christians. Later in 221 B.C. the ruler of the state Qin (Chhin) Qin Shihuandi (Chhin Shih Huang Ti) united all Chinese states as a firm believer in the elixir of eternal life with the alchemists employed at his court, the elixir of life which I'm also searching for. Little before 169 B.C. Liu Yan,[127] the Han prince-ruler of Huainan, gave to his nephew the 5th king of Han-Chinese dynasty the book Huai Nan Zi (Huainanzi). The book contained the very best description of five elements and the fire as the female qi in dualism of Yin-Yang male-female qi compiled by his Huainan eight immortals visiting scholars. Based on those equivalence principles, the Chinese have a great state already for millennia, while our European Hermans and Sigismunds, my fathers and husbands, just grab as much they could for their dynasties which all too soon sadly collapse because they forgot to produce their own children…"

Frederik had to empty two glasses of wine before he could understand all the facts his sister was filling

[126] Dzou Yen (Zou Yan, Tsou Yen. 鄒衍, about 305/340 B.C.-240/250 (Grdenić, Drago. 2003. *Alkemija*. Zagreb: Jasenski i Turk, 195)).
[127] Liu Yan (Liu An, 177/179 B.C.-122 B.C.).

his poor head with. After a while, he took a deep breath and demanded: "You became quite an erudite, my baby sister. I'm so proud of you, I really am. You do talk with such an erudition that I do not understand almost a half of your speech." Frederik took another deep breath: "OK, my nice Barbara. Let's do it your way. You could wear your light dresses for a while even if the people already refer on you as the famous black queen. But do not tell anything naughty to Ulrich because you might upset him, and his anger is much quicker than his mind. You will have a dress as you wish, but we will move the celebration to periphery where folks do not know much about our father's recent death and your nice costume will not get criticized too much. We could pass by mine and Veronika's castle and ride some 25 kilometers down south to Kolpa river and make our fest there. To celebrate the happy princely event. Then we should take a ride to Kostel to hear the special mass in Fara St. Mary's church which good old Hans Schwab of our father's generation had finally built. Their renter of three hides under the church Kristof Reuter just passed away, so we could also celebrate the new owner of those hides, the brand new Kostel leaseholder Ivan Schrabas.[128] The knight Ivan of Svibno-Planina landlords with their main property in Krško was supposed to pay for our festival there and he will bring some good Styrian wine for the occasion. The nobles agreed, that after Ivan's death the three Fara hides and whole manor will pass to Volklein Auersperg,[129] the oldest son of Theobald (Diepold) II from Turjak manor. Volklein could keep Kostel until Volklein's own death.[130] Your husband the emperor will not come to join us as he is already very ill…" The alchemistic chick Barbara was all for the party and all the flowers of the local nobility joined them. Most of the folks agreed: "Those Celje masters were not bad except that they liked to hunt the local girls. They were not a kind of proud learned nobles who carry their heavy books and speak their awful polite Latin which even our learned priest Kajclin does not understand. The literary ambitions of Celje lords were never great as their visiting Italian diplomats recognized very well. All they wanted is power, a great power, and they used to be loud heavy drinkers and eaters. Their Slovenian language has that heavy Styrian accent, but they are like one of us, although they are enormously wealthier." So, the locals approved the Celje magnates' roughness and they repeated the jokes about their love affairs with a secret wish that their own wife or daughters would not be involved. Those celebrating folks just did not imagine how close might be the end of the mighty Celje princes' dynasty which came within a decade.

The Celje magnates recently acquired friends of the noble family of Auersperg may also have originated from Teck's Swabia, namely from Ursberg. No matter what was their real origin they were already intermarried with different local Slavic and German groups for centuries when Habsburg finally got Gottschee and upper Kolpa manors in their hands after the brother of the future Hungarian king Matjaž (Mathias) assassinated Ulrich II of Celje[131] in Belgrade. Habsburgs and Auersperg knew their job better than most of their competitors and always produced a lot of male children except in Maria Theresa's later case. The Habsburgs were also able administrators and soon ordered the listings of their subjects' taxes in Gottschee, Kostel, Polland and other manors in 1490s. They wished to know how wealthy they were, and how many new subjects they got from their recent northern and southern migrations on Oldenburg behalf.

The emperor Frederik III Habsburg's[132] Kostel leaseholder Volklein Auersperg[133] already passed away, therefore the emperor leased Kostel to Volklein's daughter Susanna Auersperg who died in 1486 as a wife of her second husband Andreas Hohenwarth from the manor Kolovec north of Ljubljana. Andreas, his brother Stefan, and their father Erhard already got Polland (Poljane) manor in their leasehold in 1466. Andreas was therefore one of the rare fellows who managed Kostel and its eastern neighboring manor Polland altogether, which enabled him to switch some hides of the milers near the border of both manors from one manor to another. Andreas offered a lot of money to Frederik

III, who gave him on return also the leasehold of manor of Ribnica on May 10, 1470, Ravbar's castle of Mengeš in 1479, and Krupa manor in Andreas' final year of 1483. Andreas died under Muslim Turkish-related sable in the year 1483[134] after he used to be the governor of Celje, Provincial Governor of Carniola in 1467, and Metlika General Governor in the next year.[135] Andreas's violent death was a sad event for his son who had the same name Andreas. After Frederik died, the new emperor was proclaimed in the person of his son Maximilian I Habsburg.[136] Maximilian appreciated Andreas' familiarity with domestic affairs of Kostel. Maximilian ordered the tax records called urbars to be completed for all his manors including Kostel which was in Andreas Hohenwarth's leasehold. The emperor told Andreas: "Well, my noble dear, the new times are approaching. The way my and your father, may God bless their souls, run our lands, that funny way is no longer appropriate. The Italian Genovese-Florentine-Venetian double bookkeeping and Fugger's Swabian Augsburg business enterprises are now modern and there is no way we could avoid a reform of our enterprises."

The Habsburg guys might have been wealthy, but Barbara surpassed them all in her times. At the wedding, her royal husband signed for Barbara a contract on her widow's possessions which contained a huge territory, cities across Hungary, the mining towns in Slovakia. This would allow the widowed Hungarian queen a decent life, but only if she does not remarry. After the emperor's death, his widow should stay a widow if she wanted to enjoy all those goods. The contract was restricted to her yearly salaries of 28,000 guilders, while the surplus was due to the royal treasury. Her management also included Krems on Danube with Chamber of Commerce and Mint, as well as receipts from the mines of gold, silver, lead, iron which suited Barbara's interests in alchemy. She got financially very lucrative property, which likely made her the richest woman in Hungary. On her eternal sorrow, her lands and domains were repeatedly devastated by the Muslim intruders.

Between Barbara and Sigismund in their marriage there were apparently not too many problems, because they were much apart during Sigismund's journeys which carried him happily away from Barbara midnight hysteric escapades. Sigismund has traveled a lot through his territories, because the only way to find out what was really happening on his huge estates was to be there in person. When in April of 1419,[137] after six years, king returned to Hungary, he judged Barbara's regency up to date as unsatisfactory with regards to the Žižka's Hussite and Turkish threats of the Muslim intruders.

In 1422, Barbara's husband Sigismund had arranged their daughter Elizabeth's marriage with Albrecht V of Habsburg who supported him in the Hussite Wars. By marrying Sigismund's daughter, Albrecht also became the successor to the Holy Roman throne which was the option Barbara did not like very much. In fact, her astrological fortune-telling predicted the space of time of Habsburg Holy Roman and related ruling in amount of almost half of the millennia, which was much to long for Barbara's taste.

Despite of Barbara's doubts, the alliance with Habsburgs was a great success of the politics of Barbara's husband Sigismund and Barbara's father Herman. Still, there were many that were nasty to write about Barbara and emperor's repeated splits. Particularly, it happened that the historiographical opinions about Barbara were very negative for centuries, mostly because she was not very supportive for Habsburg Holy Roman and related ruling which lasted for almost half of the millennia, while Barbara's and her husband family houses disappeared in male lines with nobody there to defend Barbara's whereabouts. The woman Barbara, who knew how to deal with money well enough to help her husband the king, was presented as an unbeliever and a politically ill person, a kind of person with too much ambitious. Her employment with alchemy was put in a questionable light. Some

writers find this seemingly symptomatic. A similar story had been reported by historians to Barbara's contemporary Isabeau de Bavière, who temporarily represented her husband the French king in the Parisian government.[138]

Besides Enea Silvio Piccolomini, the Krakow bishop's secretary priest Jan Długosz[139] also extensively wrote on the affairs of the daughters of the magnates of Celje. Długosz' first section included notices which were linked to Anna of Celje, the daughter of the Count William (Wilhelm) of Celje deceased in 1392. Długosz mentions her arrival to Poland, her marriage to a Polish king, and Władysław II Jagiełło's coronation with Anna. Anna's mother Anna participated in the feasts. After the death of her first husband William, Anna's mother Anna remarried to the Earl of the family Teck. Anna criticized her daughter and namesake: "Dear daughter of mine, I'm glad that you are showing me your wedding dress before the marriage ceremonies. But I must disappoint you: that material of your costume is no silk at all." The younger Anna was greatly surprised and sad. She nearly put some tears in her eyes: "Dear mother, it can't possibly be true! I spent a lot of money for the dress and the merchant assured me it's pure silk, the purest of them all." The mother touched the face and hair of her only daughter with affection but continued her serious remarks: "That awful trader of yours must be a crook, a great cheater. I will get him caught one of these days, please be sure of that. To cheat a bride in her wedding day, well, that's the crime of all crimes, I tell you. I'm so sorry for you, baby, I did not spend enough time with you when you were a kid to teach you the lesson about this world full of dishonest merchants. The real dress made of silk should be so thin, that you could pack it in a small box. This dress of yours is very far from that kind. Your supposed Russian ancestors knew those things very well as they lived much closer to the Chinese producers of silk that we do. Next time, my poor daughter, try to put me in charge for your new dresses, and I will use my connections with the honest travelers who have their almost direct connections with the well-hidden Chinese ways of producers of silk…"

[138] Bader 1942

[139] Jan Długosz (Ioannes, Joannes, Johannes Longinus, Dlugossius, 1 December 1415 – 19 May 1480).

Despite of Anna the younger's wedding dress or because of it, very soon there was the crisis between the royal couple which erupted in 1407, when Władysław II Jagiełło accused his wife of adultery.[140] Probably in 1412 Anna has played the role of a kind of secret diplomat of her Celje relatives. Under the pretext of visiting her relative Barbara as the daughter of Anna's uncle Herman and the wife of Hungarian king Sigismund, Anna was transmitting the notes between Sigismund and Anna's husband, Władysław II Jagiełło. Anna and Barbara managed to negotiate a personal meeting of the two kings. Długosz mentioned Anna's death in 1416, when the grieved Władysław II Jagiełło ordered the full sorrow to all Polish churches in her honor during her funeral ceremonies. In Długosz' notices Anna was primarily a function element legitimizing Władysław II Jagiełło's rights on the Polish throne. Władysław II Jagiełło from the Lithuanian dynasty of Jagelonians got the crown in 1386. Then he baptized quickly and married with a daughter of already deceased Hungarian King Louis named Hedviga. In this way, he became a co-ruler of Hedviga, who has been on the throne since 1382. With Hedviga's death in 1399 Władysław II Jagiełło's Polish crown lost its legitimacy and Władysław II Jagiełło was even willing to give up the throne. At least Długosz thought so, even if it is a kind of improbable story because the folks naturally like the power and very seldom decide to abandon it by their own free will. In any case, by marrying Anna Władysław II Jagiełło was back in the saddle again.

Barbara and her cousin the adopted sister Anna, both married the kings. Anna's husband first wife was affiliated with the Christianization of the local areas including Baltic lands which made her a saint. Anna was not that lucky when she became the second wife of Vladislav II Jagello (Władysław II Jagiełło) in 1402 after the death of his first wife Hedviga (Hedwig) of Anjou. Like their ancestors, Anna and Barbara were known for their toughness, passion, and indulgence. "She was a very sensual woman," wrote about Barbara the humanist Aeneas (Enea) Silvius Piccolomini. "She even supposedly banned her maid's prayers." Barbara of Celje was reportedly energetic woman and her husband, allegedly due to

[140] Further Długosz' notice in his chronicle.

her infidelity, took revenge and told her to go to Oradea in 1419. After the reconciliation, Barbara received the huge payments from Central Slovakian mining towns, Zvolen Castle, Trenčanský Castle, and several castle domains in 1424 and afterwards. Barbara still rather acted against the interests of her husband. Since 1436 as a Bohemian queen Barbara led diplomatic relations with the Czech statesmen in their maternal Czech language. She was closer to Utraquists Hussite than to the Catholics, which was not her husband's wish. As the Empress Dowager, she opened new possibilities a year later. "That woman, already an old woman," said Aeneas Silvius (Enea Silvio Bartolomeo Piccolomini) about Barbara, "have the intention again to marry, after she was banished from the mind of her daughter who grew up in the hope of the throne and married the Austrian Duke Albrecht. In that situation, Barbara did not think about anything other than the joy of a new marriage." Barbara was going to marry the heir to the throne of Poland, who was then a teenager of only thirteen years of age. Barbara secretly wished to be again in the Krakow on the post of her adopted death sister Anna. Her plans failed mainly because of the power of her daughter and Barbara's son-in-law Albrecht.

3.2.1.7 Alchemy, the Queen of us All

After Barbara's politics failed, Barbara devoted more time to her intellectual and alchemistic-astrological interests designed to produce the new materials. To learn more about Avicenna's Muslim astrological-alchemical pursuits Barbara even sent her nephew Ulrich with his sixty knights to the Iberian Santiago de Compostela near the center of Moorish learning. Barbara's power was not entirely in her politic-diplomacy as soon as she learned that her reputations of astrologer-alchemist brings in even more admirations of her networks. The politics became Barbara's tool to learn more about astrology-alchemy, which was diametrically opposite to the approach of most of her Celje family members.

Barbara had not accompanied Sigismund to his imperial coronation in Rome in 1433 which formally deprived her from the crown and the related tittles as the only medieval Roman princess who failed that formality. Even more frustrating, she was not allowed to attend the solemn funeral of her own husband, something like the humiliations needed to diminish her power as much as possible. Barbara's son-in-law Albrecht of Habsburg and Barbara's angry daughter might also have been instrumental in the battles against Barbara's influences. Both Sigismund and Albrecht's networks saw in Barbara an antagonist who had enough power to disable Albrecht V as the successor to the Bohemian and Hungarian royal thrones.

Figure 3-6: The title page of Laaz' alchemical book containing the stuff he previously learned from Barbara, with a note of the year 1448 as the time of writing.

After the Hussite Wars, the royal couple temporarily reconciled, and Barbara was crowned Queen of Bohemia which greatly approved her merits in Prague astrological-alchemical circles. All doors were opened to her at once. On 11 February 1437 in Prague Barbara was crowned Queen of Bohemia in her own right just several months before her husband passed away. Therefore, Barbara's happiness in Prague did not last long. As a widow, she became an easy target for her daughter and for Barbara's nephew Ulrich. In 1441 just before the death of her only daughter Elizabeth, Barbara left for Mělník which was the usual resting place for the widow of the king of Bohemia.

Figure 3-7: Laaz' beginning of the book reportedly finished in 1448, eight years after he visited Barbara.

Very early in her public life, Barbara of Celje (Cilli) became famous for her dealing with astrology and alchemy. She frequently left her Mělník castle for her Celje family castle of Samobor 20 kilometres west of Zagreb and 90 kilometres southeast of her native Celje. Already on September 28, 1408, Barbara had her court in Samobor were she issued the order on important administrative matters of Zagreb folks[141] while she developed her alchemistic lab in the basement of her Samobor castle. Later, Barbara father was the Ban of Slavonia including Samobor during the last dozen years of his life.[142]

After their father passed away, Barbara’s brother Frederik was formally in charge in Samobor, but Barbara was more than his match. Barbara spent most of the time in the basement of the Samobor mansion which she transformed into the laboratory for her alchemistic experiments. Her own notes on her alchemic pursuits were not maintained because Barbara was the wealthiest female in Hungarian kingdom which made her quite reluctant to admit to the crowd that she is making some false precious metals in her laboratories. As the member of the highest nobility Barbara had no intentions to make her research public as the ordinary literati usually do.

TRACTATUS SECUNDUS AUREUS DE LAPIDE PHILOSOPHORVM IOANNIS DE LASNIORO DISCIPULI ANTONII DE Florentia.

Figure 3-8: Reprint of Laaz' booklet under the title Joannes de Lasnioro. Tractatus aureus de Lapide Philosophorum, In: Zetzner (ed.). Theatrum chemicum, præcipuos selectorum auctorum tractatus de chemiæ et lapidis philosophici antiquitate, veritate, iure, præstantia et operationibus, continens... Volumes I-IV. (Ober)Ursel: Zetzner. 1602. Reprint: 1613. Strasbourg: Zetzner, 4: 579-584. Here is first page 579.

The uneducated crowd is one thing a clever guy must be aware of, but the alchemical-astrological networks of Prague and Hungary knew very well all about Barbara’s merits. The best extensive critical testimony of Barbara’s alchemistic work was obtained from the records of her alleged visitor, the Bohemian alchemist Johannes from Laaz (Ledce) south of Brno in Moravia. Laaz authored *Tractatus aureus de lapide philosophorum* and claimed in the subhead and again in conclusion of his *Tractatus II de lapide philosophico* to be the student of alchemist Anthony of Florence (Antonius de Florentia), who was supposedly murdered in Bohemia[143] in a kind of the alchemistic complot. In the *Tractatus* Laaz’s

[142] Katanec, Sara. 2014. *The Perquisite of a Medieval Wedding: Barbara of Cilli's Acquisition of Wealth, Power, and Lands*. MA thesis, Budapest, 69.

[143] Benedek Láng. 2010. *Unlocked Books: Manuscripts of Learned Magic in the Medieval Libraries of Central Europe*. Penn State Press, 157.

editor finally noted the year of 1448 as Laaz's times of writing. In the advanced part of his tractate[144] after the detailed instruction on handling mercury, sulphur, and arsenic, Johannes Laaz connected his divine magisterium with the works of the new philosophers as were Hermes and Thomas Aquinas. The mercury mine of Idrija was not in operation in those days yet, therefore Laaz and Barbara got most of their quicksilver from Spain, especially after Barbara's nephew Ulrich made a pilgrimage journey to that part of the world.

Figure 3-9: Laaz' booklet with notes on Hermes and Thomas Aqunas on p. 572 and data on Joannes Lucianus on the last page 584 under the title Joannes de Lasnioro. Tractatus aureus de Lapide Philosophorum. In: Zetzner (ed.). Theatrum chemicum, præcipuos selectorum auctorum tractatus de chemiæ et lapidis philosophici antiquitate, veritate, iure, præstantia et operationibus, continens... Volumes I-IV. Zetzner, Ursel. 1602. (reprint: 1613. Strasbourg: Zetzner), 4: 579-584. This Picture was attached to the page 584 to indicate Laaz' allegations about connections between metals, their conversion, solution in water and celestial bodies as Laaz debated them gladly with Barbara of Celje before they quarreled. Johannes from Laaz connected his instructions of their alchemy with the gradual reduction of the full moon of the eight lunar stages. Of course, he did not use the heliocentric system which Copernicus promoted only a century later, although the central figure in the Sun also attributed a central position between the planets. At the same time on left part of the page in the first sentence, he denied the force of the Sun, and noted the preciousness of water baptized into wine on the right side. In the final sentence, among the other eight beauties, the Moon relied on Ennead (Enneadem, nine, Greek: Εννεάς, Egyptian letter Pesedjet) as the Assembly of the nine major Egyptian Osiris (wsjr, jsjrt) deities. They were Atum, Shu, Tefnut, Geb, Nut, Osiris as a God (mortal) change, Isis,[145] Set, and Nephthys, while the Ennead perfect hint as the sum of all the Gods. Johannes Laaz used the famous Nine Ennead obviously plus a famous son of Osiris and his sympathies were put on a versatile Isis called Horus (Hor). In that way Laaz won the universal number ten palatable. According to Laaz and probably also according to Barbara's belief, eight lunar Monads (elements, units, Greek: μονάς) were created for all people with universal Eneado number ten. Then fountain main red light again pours into Nabathea eyes, probably connected with commercial influential Arab tribe of the Kingdom of Nabatea in the days of Christ.[146] Occult interpretation of the final instructions for the great process of alchemy called Ars magna from the coffers of transmutations made by Johannes from Laaz who shared Barbara's beliefs regardless of the amount of gold that any of them may create by the mysterious mishmash of their promising chemicals that could undoubtedly also help the contemporary impoverished folks.

Besides sulphur and mercury, Johannes Laaz also advised the use of ones' own naturally produced sperm, female liquids, and blood after the triple distillation. The distillation of those days was quite a novelty which the Arabic traders introduced in

[144] Johannes from Laaz. 1611. *Tractatus II de lapide philosophico/ Tractatus aureus de lapide philosophorum*, page 8, unpaged.

[145] Transformed into a name of modern Islamic State; Isis (Aset, Iset) was Oziris's maid and sister as the protector of nature and magic, which is not entirely in the frame of Islamic State as interpreted by Trump, Putin, and most of all Merkel.

[146] Octas in monadam lunae projecta creat Enneadem, è quibus omnibus Decas oritur numerus omnis atq, universus. Ubi tamen fulvus fons fundit oculatam Nabatheo cardine lucem (The eighth casted monades of the moon create the Ennead, the number of all of which gives rise to all the ten, which is all the men. There, however, the fountain of the red light pours forth of the hinge in the eyes of Nabathea).

Europe from the Chinese headquarters mainly for alchemistic or medicinal purposes while the first alcohol distillation was available in the Italian school of Salerno just several decades before Laaz put his foot in Barbara's lab. The strong alcoholic distilled spirits gained their popularity already in Barbara's era, but she served none of them to Laaz because she preferred to keep Laaz' head sober. Barbara was aware that the Chinese Yi Di made great efforts to make mellow wine with fermented glutinous rice. She even knew about Du Kang,[147] who lived or even ruled during the Xia Dynasty[148] and invented making top-notch liquor with Chinese sorghum beans.[149] But Barbara was a kind of early feminist, therefore her favourites were the female Alexandrian proto-chemists focused on metallic transformations, while the eternal life was not their greatest goal. Barbara liked mostly the legendary Maria the Jewess[150] who used her water baths and *kerotakis* to collect vapours in sealed vessel with copper sheets in vacuum. For Barbara, her predecessor Maria the Jewess was considered as the earliest proto-European, or in fact rather African alchemist and the earliest female user of the vacuum producing techniques which also pleased Barbara. The Alexandrian researchers pretended to be useful in industry, which made them suspicious in the eyes of the Roman Emperor Diocletian of Split and almost similar fate dogged the Chinese alchemists four centuries and the half before Diocletian. As a ruler, Barbara was far from being opponent of any kind of alchemistic research. Just like Barbara herself, the Muslims had considerably less fears of the alchemists' secrets compared to Han-Chinese of Catholic Europeans. The Arabic alchemists introduced the distillation from Chinese, Alexandrian, and other networks for the processing of etheric oils in 9th century and of wine in 11th-12th century while the discovery of the distilled alcohol maybe took place in South-Italian Salerno Medical School. The alcohol was used just as a remedy primary against the black death pest up to 13th and 14th century until the strong drinks widely spread in 16th century[151] as a kind of strong intoxication.

The fractional distillation of Florence born alchemist Taddeo Alderotti,[152] who used to be the professor of medicine at the Bologna University before he retired to Venice, was still a novelty in Christian European headquarters. The fractional distillation was one of Laaz's favourite tools as he spent much of his times in Italy and learned all the details almost from their very sources. The technical details of fractional distillations were one of the top Barbara's priorities and one of the main reasons why she welcomed Laaz' visit to learn more about the new Italian technologies borrowed from the ancient Chinese headquarters although Alderotti died few years before Marco Polo's Chinese travelogue was available after Polo's supposed narration in Genovese prison in 1298/1299. For one reason or another Barbara failed to visit Italy for her husband imperial coronation in Rome on May 31, 1433, which made her very willing to hear all which Laaz possibly could tell her about the new Italian inventions.

The alchemists like Barbara and Laaz considered the colour as the most important sign of change of their artefacts.[153] The Sun, Moon, and five planets corresponded to the seven metals which sometimes exchanged their connections with the nebular objects. Barbara took a great interest in a stuff like that and tried to learn more about it from Laaz who was also known as a kind of magician. The short independent addition to Johannes Laaz' text was dedicated to the abbot Johannes Trithemius (1462-1516) who became famous with his cryptography and supposed magic, although he did not really approve the alchemy.[154] Barbara was aware of those Laaz' works although Laaz supposedly put them in his final readable form some eight years after he visited Barbara's alchemical lab. As all those novelties, Laaz's opinions widely circulated through the networks of somewhat secret alchemistic communities well before the publication of them in

their final form. Barbara was among the persons with the best social connections of her time and she quickly mastered all the traches and stories of alchemistic community worldwide, even if they were supposed to be the secret ones.

Figure 3-10: The title page of Basilica chimica of Oswald Croll (* about 1560 Hessen-Kassel; † 25. 12. 1609 Prague) falsely but profitably attributed to Basilius Valentinus in a book which the count Volf Engelbert Auersperg (Turjaški) and his brother prince Johan Weikhard kept in their Ljubljana Library.

Johannes from Laaz mainly achieved his fame in Italy, where he worked on aurefaction and transformation of metals with no apparent luck. Due to failures in the transformation of metals he disappointed the local rulers and had to flee from Italy. He got even the funny nickname Lasnioro (Laz-Nien-oro) as the Italian expression for »Laz no gold" which could also have other meanings. After fleeing from Italy, he traveled extensively, learned all about the alchemistic networks around, and wished to learn even more by visiting many alchemistic labs where he tried to figure out the strictly hidden alchemistic secrets. Laaz therefore also visited the palace of queen Barbara in Samobor and her alchemistic lab in the basement. What he saw and Barbara's trials carried out in his presence were fascinating, not just because of Barbara's knowhow, but also because of Barbara's high social position. Laaz described his experiences with Barbara in his book *Via Universalis* ("universal way"). Part of the text of that Laaz's work was published in the seventh edition of the alchemical work *Currus Triumphalis Antimonii* ("Winning of antimony wagon" or "Triumphal antimony wagon.") which was attributed to the alchemist Basilius Valentinus.[155]

Figure 3-11: Barbara of Celje portraited as a Venus of her astrological pursuits, which was believed to be equivalent of copper of her deepest earthly lab matters (Konrad Kyeser, Bellifortis, manuscript 1360, folio 002v, Bibliothèque municipale de Besançon, first half of the fifteenth century, "Liber de septem signis", Bellifortis-fragment).

Johannes from Laaz wrote as follows on his mishmashes with Barbara: "I heard several rumours of the queen, the widow of King Sigismund of

[155] Paušek-Baždar 2008. Königin Barbara zu Cilli als Alchimistin in Samobor. *Godišnjak Njemačke narodnostne zajednice* 15/1**:** 277.

venerable memory. All talked about her knowledge in the physical arts, so I went up to her to try it out. She gave me very clever answers. I saw that she took mercury, arsenic, and something else which I did not recognize. She made the powder from which the copper was whitened. That substance did not withstand the mechanical experiment with a hammer although it withstood the scrapping with the sander. In that way, she defrauded many people".[156]

The above experiment in Laaz' description was known very well in the alchemist literature for a while. The main part of it was important for bonding of the copper with mercury and arsenic, wherein the compound obtained a silver colour which resembled the precious metal. Pseudo-Democritus already in the 2nd century discovered the secret of changing the colour of copper into the colour of silver,[157] which meant that the procedure was not at all Barbara's invention.

Laaz continued his valuable report, which might have been somewhat adapted to fulfil Laaz's own wishes: "I also saw how she heated copper sprinkled with some powder that she yelled in copper and made her copper coloured as fine silver. When she re-solidified copper, the copper has become ordinary as it was before. She showed me there some more fake arts." Laaz certainly knew the tricks of those sorts because he also used to cheat folks in his good old Italian times. And Laaz testified further: "Next, she took crocus Martis (Crocus Martis - literally "Mars saffron" iron oxide ($FeSO_4$), which normally contains a proportion of impurity), some saffron of Venus (copper lime), and other powders. She mixed them and thereby cemented all those parts with gold and silver. The metal had the outside and the inside appearance of fine gold, it really looked fine from inside and outside. But when she melted it, the mixture lost its colour. In those ways, she has cheated many traders".[158] The first above described process was also known for a long time in the alchemic literature. The famous Stockholm papyrus (Papyrus Graecus Holmiensis, dated about 300 AD) already contained such stuff as it presented craft recipes written in Demotic Greek script. The Stockholm papyrus had 154 recipes for dyeing, colouring gemstones, cleaning (purifying) pearls, as well as for the imitation gold and silver. It also reported of bleaching of copper (halkoy leukosis) with the arsenic. The procedure used to be performed with arsenic, so that realgar (red arsenic sulphide, α-As_4S_4, arsenic sulfide mineral, "ruby sulphur" or "ruby of arsenic") and arsenic (poisonous dust, arsenic trioxide) were thrown into the molten heated copper. In the second procedure, the alchemists used Martis crocus (Crocus of iron) or iron (III) oxide Fe_2O_3 for the yellow colour, while copper oxide was red. The hardening in alchemy designated the process of discharge of gold from silver and that was the art which the wealthy Barbara wished to achieve while the poor Laaz was maybe also remotely dedicated to that goal.

In Barbara's laboratory, which she headed with the little help of her assistants, the metals and metal oxides were heated to the glowing temperatures in a container together with a simple salt and copperas, the so-called cement. Thus, the cleansed gold which Barbara got was even much cleaner than the natural one. That kind of gold later in the era of iatrochemistry became very useful as a medicine in the form of thin gold leaves, or in the form of potable gold. The potable gold elixir was indeed the gold dissolved in Aqua regia, which was also called "royal water" or "king's water" as a mixture of alcohol and lemon juice.[159] The funny Laaz's excerpt ended as follows in a spirit of his times which were full of colourful scenes: "I have seen many frauds and scams, so I told her that this reproach of her is bad. She wanted to jail me, but I escaped with God's help."[160] The clever Laaz never explained the way he managed to escape from the almighty queen. His intention was to provide the testimony about the alchemical laboratory research of the wealthy folks as a kind of propaganda for his

own up to date failed ars magna. As the grandma of the Habsburg ruler Ladislaus V the Posthumous, Barbara was the initiator of a huge row of documented Habsburg alchemistic rulers including the emperors Rudolph II and Leopold I. All of them borrowed from Barbara's lab in all aspects.

Figure 3-12: Barbara of Celje portraited as a blue Venus of her astrological pursuits, which was in blue color even more equivalent to copper of her more earthly lab matters (Konrad Kyeser, Bellifortis, manuscript 1360, folio 002v, Bibliothèque municipale de Besançon, first half of the fifteenth century).

The Bohemian alchemist Johann von Laaz supposedly described Barbara's alchemical experiments in a manuscript written about 1440, which was later lost. The doctor Benedict Nikolaus Petraeus reported about Laaz' testimony in the preface of his edition of the *Chymischen Schriften* (Chemic writings) of Basilius Valentinus. The authorship of the supposed Benedictine Basilius Valentinus was probably a hoax. One of the real authors behind that penname was the Paracelsus-fan alchemist and poet Joachim Tancke (Tancky, 1557/1559 Perleberg in Brandenburg-1609 Leipzig)[161] who became the Leipzig professor in 1589; as the rector there he repeatedly wielded his stick. Until in 1624 he participated in the hoax Basilius Valentinus' publication of Johann Thölde of Hesse (1565–1624), a city chamberlain in Frankenhausen and co-owner of the plant used for the salt production. He published his felicitous alchemy under the fanciful name of the supposed German Benedictine monk Basilius (Basil) Valentinus.

Barbara liked Laaz (Laatz) in the first place and Laaz welcomed the opportunity to examine Barbara's alchemical knowledge. She had answered Laaz' sophisticated questions "with feminine subtlety." In front of Laaz' somewhat surprised eyes, Barbara with a powder of mercury, arsenic, and concealed ingredients, dyed her copper white and thus supposedly converted it into silver. Laaz, however, found that the product was really like silver, but the metal was not strong enough to resist the hammer. Barbara also introduced to him many similar "art pieces", including "iron ice", "copper lime" and other powders of "gold", which, however, lost its color when Barbara melted it. Laaz (Laatz), who was himself a kind of hoax, wrote that she had deceived many merchants in her times, which was not very likely because Barbara was extremely wealthy, and she really did not need that kind of additional incomes. When Laaz accused her of deception, she threatened to imprison him, but he had "come back from her headquarters with God's help" once again. Other princes of their times also dealt with alchemy, especially Johann von Brandenburg-Kulmbach, who politically promoted his alchemistic networks to smooth his good relations with the House of Brandenburg.[162]

MA thesis, Budapest.

Figure 3-13: Barbara and her husband in the council of Constance enrolled in all the glory of the supreme rulers.

The pseudo-alchemist Laaz was just one of the many visitors in Barbara's alchemical-astrological networks which were well known to the interested learned circles. Besides the erudite, the common folks also talked a lot about Barbara's occult research, which put the work of Barbara in quite a different limelight. Many legends were spread about her apparently black magic and just her highly advanced social status saved Barbara from the troubles. She might have suffered even harder than Veronika, but all those crowns on her head protected her.

Barbara was even happy enough to survive her only offspring because the poor daughter died in her early thirties in 1442. Barbara spent most of the rest of her life in Mělník, where she allegedly devoted herself to the occult sciences. She loved to inspire herself into the mystical research as she was concerned with alchemy and astrology, all of which felt deep into the hands and minds of many of her contemporaries. This fame of Barbara went so far that later even the legends arose. In some of them she would have evaded as a vampire during the Constance Council, and still today some memories of Barbara's whereabouts tell the story that she should be feared in the Balkans as a blood sucker. The signs of her evil obituary as a "German Messalina" were promoted by Barbara's dynastically competing Hapsburgs: "She fell into such an antichrist abuse. And her body and soul would die together".[163] That was certainly a hard wish.

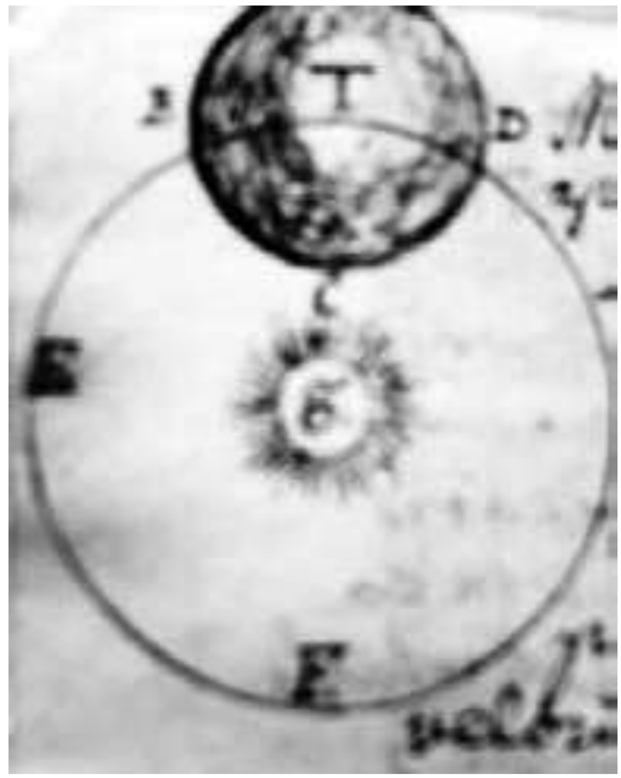

Figure 3-14: The Ljubljana based Franciscan lecturer of philosophy with physics illustrated the Copernican motion of planets in vacuum soon after the suppression of Jesuit order (Anonymous, 1774-1775, 8r; F).

Barbara spent her last years in Mělník 35 kilometers north of Prague above the huge vineyards. She was also frequently in Hradec Králové (Königgrätz) a hundred kilometres to the east which was also the ordinary residence of the queens.[164] The aging

Barbara enjoyed the protection of the powerful Bohemian future king of the Utraquists moderate Hussite party named Podebradski (Jiří Poděbrad, 1420-1471). Podebradski was adopted as the executor of Barbara's rights in 1445. With George Podebradski backing her, Barbara joined the winning side of Hussite conflicts which her husband and nephew did not particularly approve. George Podebradski was a quarter of century Barbara's younger and as the real gentlemen he took care for aging Barbara.

After Barbara's long postponed death, George Podebradski got Mělník and all her cities which she received as the dowry upon her coronation as the Bohemian queen. On 11 July 1451 Barbara died in Mělník of plague that raged there more-or-less because she was approaching her sixties which was quite an old age in her times. Barbara tried to use her distilled alcoholic beverages to stop her own disease as she learned from Laaz a dozen years earlier, but her aging body was willing no more. The last notice she received was the happy one as her beloved native settlement of Celje finally received its town privileges on April 11, 1751. Barbara's brother Frederik was in charge there and he hurried to inform Barbara about that happy news. Exactly three months later Barbara's days were over, while Frederik had another three years to think about all kinds of everything. Barbara's royal body was transported to Prague with all custom ceremonies included. Her Czech friends buried her remains with great honors in the royal tomb in the chapel of St. Andrew and Silvester of St Vitus Cathedral in Hradčany in her beloved Prague, where many other European rulers were also buried. George Podebradski (Jiří Poděbrad) was crowned as the king of Bohemia after the premature deaths of Barbara's nephew Ulrich and Ulrich's protégé Barbara's only grandson Ladislaus V the Posthumous.

Barbara survived as a symbol. She was not always a good girl, but she was certainly a clever one all the times. Her research in sciences and technologies was performed in completely other ways in her space of times and social structures compared to later circumstances, which makes someone hard to judge Barbara's merit from the contemporary point or view of publish or perish.

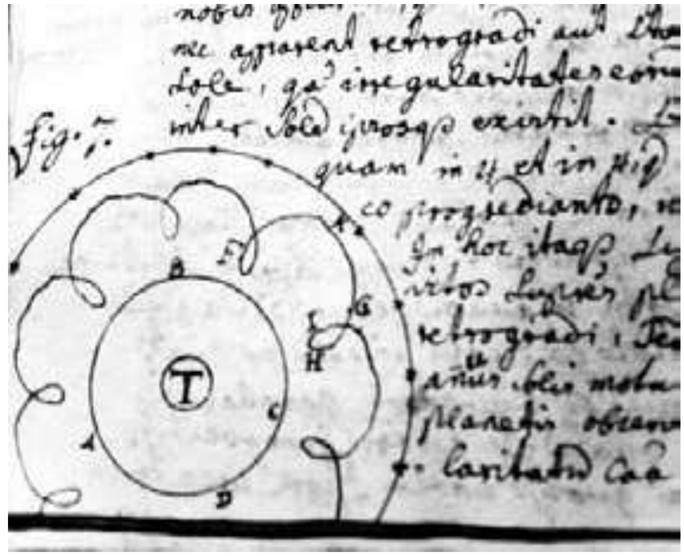

Figure 3-15: The Ljubljana based Franciscan lecturer of philosophy with physics illustrated Ptolemy's motion of planets in vacuum soon after the suppression of Jesuit order (Anonymous, 1774-1775, 8v; F).

3.2.2 Copernicus on Vacuum

3.2.2.1 Introduction

Barbara was a pioneer of the long series of researchers of new materials connected with the lands inhabited with Slovenes. Barbara loved her new materials produced in her alchemistic lab, while she also liked astrology. It was too early for her to promote heliocentrism which gained ground with Copernicus' work a century after she passed away. A few years ago, we discovered in Ljubljana the mistakenly forgotten Copernicus work from 1566. The discovery confirms the exceptional scientific ambitions of Slovenian ancestors. What does it have to say about the beginnings of vacuum techniques in Slovenia, as Copernicus used to be the beginner of modern new science in Europe?

Copernicus died a hundred years before Torricellian experiments. So, of course, on the experimental plane, Copernicus still could not think about the vacuum technique in a modern way. By the way, he could not pass without the vacuum issue, since the later Galilean clouds began to collect over him. What was Copernicus's opinion about emptiness?

Figure 3-19: Frombork (Frauenburg) near the Baltic Sea in the then Prussia, today's Poland, where Copernicus died on May 24th 1543

3.2.2.2 Copernic's Atoms and Vacuum between them

Copernicus' universe, or the solar system, was infinitely large in comparison with the Earth. He also considered invisible atoms that reach a noticeable size only when they are collected in large enough quantities.[165]

Atoms of Democritus, Epicurus and Leucippus, of course, presupposed the existence of a vacuum between particles of matter. Although he did not explicitly mention the vacuum, Copernicus assumed his existence on Earth with his discussion of the atoms. He has not yet asked questions about how the planets move around the Sun without friction, although the other researchers have already written about it.

Besides the Ljubljana Jesuits, the Franciscans of Ljubljana also acquired Copernicus' book in its second edition. They also got astronomic-geographic work of Johann Schöner (1477 Karlstadt am Main-1547 Nurnberg). After Johann Schöner passed away, Gemma Frisius (1508-1555) edited his book. In Nurnberg, Rheticus' first teacher of astronomy was Schöner. Rheticus later became the only relevant student of Copernicus. Therefore, Schöner became the early reader of Copernicus' ideas which Rheticus summarized for him in Narratio *Narratio Prima*, as noted in the title of Copernicus' second edition. Schöner's book was printed nearly simultaneously with Copernicus' first edition, and the Franciscans of

[165] Copernicus, 1998, 58-59.

Ljubljana bound it in parchment with some additional carton coverage. The part of other book used for binding must have belonged to 9th division of Ljubljana Franciscan library and not to 10th division to which Schöner's work should be catalogued. Gemma added to Schöner's book his own unpaged work as the last third part of it in 1548 and concluded the edition with Schöner's rules for the uses of sphaera armiralis (κρικοτὴ σφαῖρα). The previous owner of the Ljubljana Franciscan book was Michaelis Khernis Gablosensis (Černe Chernis, Gablkouer, Gablkoven) who got the item from Abraham Rucly on 21. 7. 1602. Before the title page there is partly preserved bookplate dated in (15)68. The first geographical Ptolemy's part of the book had the table of geographic longitudes of cities[166] with descriptions of Austria, Styria, Carinthia, Hungary, but not Carniola. The author added the geography of American islands and peninsulas including the Yucatan and Jamaica,[167] which certainly interested the Franciscan missionaries of Ljubljana.

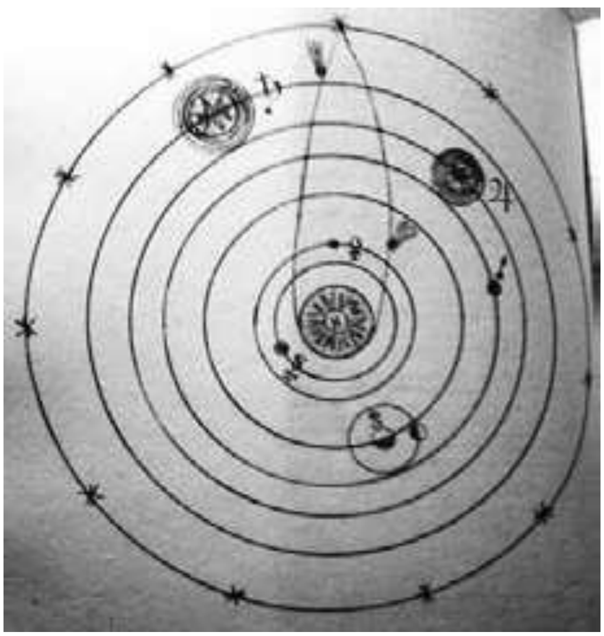

Figure 3-20: The Ljubljana based Franciscan lecturer of philosophy with physics the Bavarian Theofil Zinsmeister illustrated the Copernican motion of planets in vacuum (Zinsmeister, 1799, 2: 156; F).

Gemma wrote the introductions to the first part of the book long before their printings. The introduction to the first third of a book was dated in Antwerp on 1. 10. 1530 and the introduction to the second third Schöner (not Gemma) dedicated to Johan Khreutter in Leuven in February 1514. Johan Khreutter served as a secretary of Hungarian queen Mary of Habsburg (1505 Brussels-1558 Spain), the widow of Louis II Jagiełło (1506-1526 Mohács). The granddaughter of the emperor Maximilian I, queen Mary, served as the governess of the Netherlands for her brother the Emperor Karl V. Gemma dedicated to Johan Khreutter his own treatise on the astronomical rings in 1534.[168] Johan Khreutter was a friend of Cornelius Agrippa. The astronomical rings were an early astronomical instrument consisting of three rings, each representing the celestial equator, declination, and the meridian. It can be used as a sundial to determine time, if the approximate latitude and season is known, or to ascertain the latitude. It was a simplified, portable armillary sphere, or a more complex form of astrolabe.

Figure 3-21: The title page of the geographic-astronomic book of Gemma Frisius and Schöner in the Franciscan library of Ljubljana.

166 Schöner, Gemma, 1548, 72r-72v.
167 Schöner, Gemma, 1548, 39v, 71r-71v.

168 Gemma, Usus annuli astronomici. In: *Petri Apiani Cosmographia* Antwerp: Aegidius Coppenius and Arnoldus Berckman, 1539, folio 2r.

Figure 3-22: The title page of Schöner's instructions for the use of armillary sphere (Sphaera Armillaris, κρικοτὴ σφαῖρα) in the Franciscan library of Ljubljana (Schöner, Gemma Frisius, 1548, 89r).

The second third of a book was divided into twenty paragraphs. Many funny illustrations of visually measured heights of stars or towers were added; at the end there was again the table of geographic longitudes of cities. Schöner's rules for the uses of sphaera armiralis (κρικοτὴ σφαῖρα) were published in 1548 with undated introductory greetings in epigram of sphaera armiralis (κρικοτὴ σφαῖρα). He cited Regiomontanus' opinion about the shape of meridians in Arctica. In the last part the unsigned Schöner described the types of sphaera armiralis (κρικοτὴ σφαῖρα) dedicated to the bishop of Bamberg named Georgio, in fact Georg Schenk von Limpurg (1470–1522) who excelled as the trusted imperial advisor of Maximilian I. Schöner tried to figure out the distances between the stars and the Sun in zenith, as well as the apparent solar and lunar heights (altitude). He used eight domus for prophecies based on Ptolemy's Almagest.[169]

The other early owners the Copernicus' Book, the Jesuits of Ljubljana, used a lot of books of Copernicus' contemporaries who also considered vacuum. Among them was Benedetti,[170] a disciple of Tartaglia.[171] He published some evidence of Copernicus' assumptions and paved the way to Galileo's dynamics with his ideas. In 1558-1566, the Copernicus fan Benedetti was a mathematician at the court of the Duke Ottavio Farnese (1524-1586) in Parma and later at the court of the Grand Duke of Savoy in Turin. He wrote the book in the form of letters to various scholars, among others to Nuñez,[172] the first professor of advanced mathematics at the University of Coimbra in Portugal.[173] Benedetti wrote about many questions, including the squaring of the circle,[174] or the temperature differences on the Sun[175] interesting in connection with the sunspots discovered later in 1610. He discussed the vacuum in the Heron vessel, the weights of air and oil.[176] Benedetti used the arguments of Giovanni Filippo from the 6th century to challenge Aristotle's assumption of the impossible infinite speed of missiles in a vacuum.

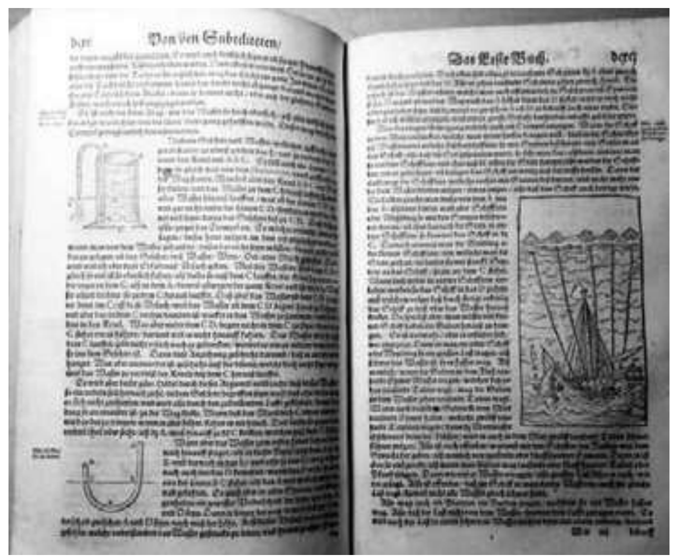

Figure 3-23: Cardano's siphon with submarine in the Franciscan library of Ljubljana (Cardano, 1627, 690).

This seemed to him particularly important as a continuation of Benedetti's teacher Tartaglia's

[169] Schöner, Gemma, 1548, 2r, 39v, 71r-71v, 73v, 74v, 83v, 85r, 87v-88v, 94v. 103r, 104r, 112r, 114v.

[170] Giannbattista Benedetti (Benedictis, * 1530 Venezia; † 1590 Torino).

[171] Bogoljubov, 1983, p. 39; Cantor, 1900, 2: p. 388, 565-566; Benedetti, 1599, p. 241, 241, 261. Niccolo Fontana called Tartaglia (* 1499; † 1557).

[172] Pedro Nuñez (Nonius, * 1492 Alcazar del Sol; † 1577 Coimbra).

[173] Cantor, 1900, 2: 388; Benedetti, 1595, 214.

[174] Benedetti, 1595, 303.

[175] Benedetti, 1595, 358.

[176] Benedetti, 1595, 225-227.

research of the movement of cannon missile.[177] Of course, the research of the vacuum became particularly interesting after Torricelli, Guericke and Auersperg's experiments half a century after Benedetti's death.

Benedetti's letters (1599) were probably the first mathematical work procured for the Jesuit college in Ljubljana. Copernicus, Galileo, and vacuum issues were by no means foreign to Slovenian Jesuits even at the time when the discussions of these ideas were officially restricted in Catholic countries.

Figure 3-24: The first page of the list of the mathematical part of Auersperg's library that was drawn up in Ljubljana fourteen years after the participation of the Auersperg Prince at the Guericke's experiments in Regensburg. The census lists Galileo, Harsdörffer, and Kepler's books (Haus-, Hof- und Staats-archive, Fürstlich Auerspergsches Archive, VII Laibach, A 14/4 conv. 1 Laibach-Fürstenhof 1729-1895, Vienna, Minoritenplatz 1, Catalogus, Septima Classis sive Mathematica, 1668, 331).

In the early days Carniolans purchased the books of Tartaglia's sworn opponent Cardano.[178] In Copernicus' time Cardano designed procedures for production of vacuum by the condensation of steam. The Jesuit Porta[179] developed Cardano's ideas into his attempts to lift water in a vacuum tube, which was adopted by Edward Somerset, 2nd Marquess of Worcester (1602/1603–1667) in 1663 and finally by Boyle's assistant Denis Papin.[180] Porta was thinking about a vacuum in the universe, as well as on Earth, after the example of Pythagoreans and Heron's experiments in Alexandria.[181] The inhabitants of Ljubljana had many Porta's works, and the Carniolan family Rechbach had even two different Porta's prints.

A century after the publication of Copernicus's book, Prince Auersperg[182] helped Otto Guericke during their vacuum experiments in Regensburg. In any case, he already learned a lot about a vacuum as a young man in Ljubljana. He even read about vacuums in his rich library in Ljubljana in the mature years. His important basic role played in Guericke's beginning of the vacuum technique is not a complete surprise: Ljubljana of those times was one of the centers of the exchanges of ideas of modern science during the Renaissance between the Baroque Italy and the imperial humanists residing in Vienna. Among other things, Auersperg in his library in Ljubljana kept a book on hydro-technics and vacuum experiments of the Prague professor and rector Dobrzensky de Nigro Ponte[183] from a famous Prague medical family, which was strongly criticized by the nobleman Rain[184] from the castle Strmol by Cerklje near Kranj. Of course, today might be difficult to evaluate which side in that quarrel was then supported by the prince Auersperg, but certainly his experience with vacuum experiments influenced Dobrzensky's research.

184 Janez Friderik (Joannes Frideric) von Rain.

The first Slovenian vacuumist, Auersperg, did not only acquire the works of foreign authors in his library, which was the best private collections in the Baroque Europe at that time. In a prominent place he also had a book of Carniolan professor of mathematics Kobav.[185]

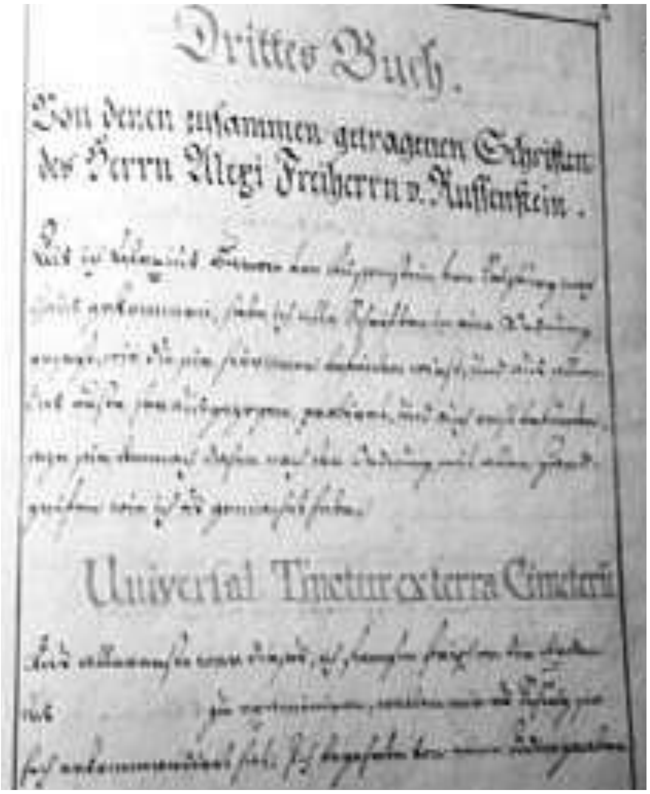

Figure 3-25: The title page of Aleksander baron Ruessenstein's clean copy of his edited manuscript book on philosophical stone in the Franciscan library of Ljubljana (Ruessenstein, 1694, 1 (FSLJ- 29 F-54).

3.2.2.3 Conclusion

The surprising discovery of Copernicus's books in Ljubljana is reflected in a more anticipated light if we connect it with an extremely important basic role played by the first Auersperg Prince in early Guericke's vacuum experiments after the Galilean quarrels about Copernican doctrines. The findings of this kind certainly leave a new self-esteem of Slovenian vacuumists, the successors of so famous ancestors.

3.2.3 *Vacuum of Trubar's Days*

3.2.3.1 Introduction

At the time of Trubar's birth, the most important Slovene professors of humanities taught in Vienna, where they occupied so many main chairs and positions as never before or after. On 14 April 1528 Primož Trubar enrolled at the University of Vienna and listened to the philosophy with physics in the classes of the most prominent Slovenian scholars, such as Styrian Andrej Perlah, while the Zasavec (born by Sava riverbanks) Matija Hvale had already died before Trubar's studies. Nevertheless, Trubar naturally read Hvale's philosophy of nature with thoughts about a vacuum, which may have been preserved in the NUK in Ljubljana right from Trubar's library. Unfortunately, several months after the arrival of Trubar, the Turks under the Suleiman the Magnificent besieged Vienna for their first time; therefore, Trubar did not finish his studies, but returned to Trieste. Similarly, most Trubar's classmates run away, so the number of students enrolled at the Viennese University from close to 700 in Trubar's boyish years fell to zero in 1532.

In Vienna, some of Trubar's colleagues studied at least occasionally, among them Adam Bohorič, who reached the first academic degree of Baccalaureate in Vienna in 1547. The accumulated thoughts about vacuum and other puzzles of the then natural science in Vienna influenced Bohorič's purchase of five hundred books, his rectorate in Ljubljana and, last but not completely least, his own writings. At least Bohorič and Trubar were among the Slovene Protestant heirs of a rich tradition of reflections on the vacuum of the Viennese professors of the Slovene genus.

The older Trubar collaborators studied in northern Italy, among them the bishop Peter Bonomo in Bologna (1487),[186] and Peter Pavel Vergerius the younger in Padua until 1523.[187] Most of Trubar's younger colleagues studied in Tübingen, including his sons, Jurij Dalmatin, Frischlin and Bohorič, since the Duke of Württemberg specifically advocated the spread of Protestantism in the Inner Austrian lands with Carniola included.

3.2.3.2 Terpin's List of Upper Castle (Gornji Grad) Books

What did Trubar's think about vacuum? Trubar's authored books were extremely religiously oriented,[188] while several natural-science thoughts are in his letters and especially in the books of his library. Trubar repeatedly praised Luther's chief co-worker, Philip Melanchthon, whose physics with vacuum descriptions was also used in Ljubljana, while the Franciscan in their library used Melanchthon's foreword to the translation of Euclid.[189]

Figure 3-30: Title page of Index of prohibited books of the Pope Innocent XI in the Franciscan library of Ljubljana (Innocent XI, 1726 (FSLJ)).

Melanchthon was convinced that nature at first avoids infinite quantities, while as the second nature avoids vacuum. On the third point nature does not allow several simultaneous positions of the same body contrary to Heisenberg's uncertainty principle published half of millennia later. On fourth point the nature refuses penetration into the substance as the Pauli's exclusion principle formulated half of millennia later, and in the ultimately fifth point the nature avoids the destruction of the substance in an early form of law of conservation of energy which was fully understood only three centuries later. Melanchthon denied the possibility of a vacuum in nature and gave an example of a water clocks where the water fills up completely any created voids. In the vacuum, movement is not possible: Melanchthon's standard scholastic responses, as well as the continuation of the chapter on thinning and condensation was purely Aristotelian, just like his description of time and infinity.[190]

Figure 3-31: Self-explanatory illustration at the Title page of Index of prohibited books of the Pope Benedict XIV in the Franciscan library of Ljubljana. He finally lifted the sharpest ban of Copernicus' book, but he kept Trubar's works in his index (Benedict XIV, Index Librorum Prohibitorum, 1758 (FSLJ)).

Figure 3-32: The Grammar lady as a guide leads the student through the knowledge house in the book noted in one of the oldest Slovene preserved catalogs of books of Terpin (Reisch, 1508).

After the Tridentine council, Trubar's writings went to the index of prohibited books, where Frischlin's collected works joined them in 1603.[191] The lists of books of Trubar and his colleagues' collections were not entirely preserved, but after the confiscations they were mostly brought to the Gornji grad (Upper castle) Diocesan Library in southern part of Styria. Some might have been burned, but those acts are not very probable considering the huge cost of books in those days. Many works from the libraries of Carniolan Protestants were transferred to Upper Castle, including the legacy of the Protestant school teachers of Ljubljana Lenart Budina, his son Samuel Budina, and 274 Primož Trubar's books inherited by his son Felician Trubar. After selling his Ljubljana house in 1569, P. Trubar presented a box with books to the Carniolan "Land and Church"[192] as the basis for a library of Estates General or even the first public library on Slovenian soil,[193] where many opinions about the vacuum could be read. In 1604, the provincial Estates general attempted to smuggle their books hidden in the barrels to Swabia, but their cargo was seized and taken to the Upper Castle (Gornji Grad) of Styria.

Half of a century later, the Diocesan Vicar Terpin in Upper Castle (Gornji Grad) catalogued the former books of the director of the Protestant school Lenart Budina, including his copy of natural science of Gregorius Reisch, bound in wooden covers.[196]

[196] Terpin, 1655, 16^{r}; Simoniti, 1974, 31.

Reisch earned his bread as the confessor of Emperor Maximilian I and the Prior to Charterhouse of St. John the Baptist near Freiburg im Breisgau. He dealt with arithmetic, music, architecture, perspective and astronomy with excellent drawings under Dürer's influence. He wrote about the vacuum, especially when describing the universe. His first illustration was a sketch of the human eye, and under the heading Typus grammatio, he painted Mrs. Grammar, who leads the student along the path of knowledge through a five-story house. On the third floor, the lady logic was waiting, and on the fourth there was the lady physics with the theories of vacuum and moral teachings.[197]

3.2.3.3 Hvale

The most important Slovenian thinker about the vacuum of Trubar's days was Hvale from the vicinity of Litija. Hvale's Philosophy of Nature (1513) was also among the southern Styria Gornji grad (castle) books of the Bishops of Ljubljana. It was catalogued by Terpin. Hvale's book was the oldest printed vacuum reading published by naturalists and philosophers of Slovenian descent.

At least in 1502, Hvale began to compose his only publication, when he was a magister, a treasurer, head of the Faculty of Philosophy and head of one of the main student dormitories in Vienna. He was praised as the dean of the Faculty of Philosophy elected for a half-year time on 12 April 1510.[198] He overhauled the nominalism that had been ruling at the University of Vienna since its foundation in 1365. At the same time, he defended humanism, which was supposed to attract students again to Vienna once they had begun to prefer Krakow and other universities, since even Copernicus studied in Krakow and not in Vienna. In 1492-1502, the Slovene astronomer Perger led the fight for humanism in Vienna as the author of the first Slovene grammar,[199] and continued to praise Hvale as the most prominent scientist-philosopher of humanism with its beginnings in the newly shaped ideas about the vacuum.

On 10 January 1512, Hvale addressed his introduction of the unpaged book to his Carniolan colleague, the Radovljica native Pavel Obersteiner, the Viennese Master of Philosophy, who reached his noble status in that same year. In 1513, Emperor Maximilian I ordered a dictionary of the Slovene language to his counselor and secretary Obersteiner, who mastered then highly esteemed art of the secret encrypted writings. Obersteiner became a provost in cathedral, and between 1516 and 1544 Chancellor of the University of Vienna as an opponent of the Nuremberg Lutherans.

A Swiss doctor and Mayor of Gallen, the later Protestant Joachim Vadian, coined the introductory epigram for Hvale,[200] which proves Hvale's involvement in Viennese humanistic circles. Hvale's pupil and then co-worker Vadian lectured on humanities in the years 1516-1518. Along with Tannstetter and other educators, he was a member of the Viennese Sodalitas litteraria Danubiana, and thus operated under the same humanistic patterns as the author of book about geometry in Terpin's library named Johann Vögelin.

Hvale designed his booklet as comments on Parvulus philosophiae naturalis, which were used in Vienna to achieve academic grade of Bachelor of Philosophy with Natural Sciences included. Hvale and his collaborators have already devoted more time to their studying of natural sciences than to other renowned works. Hvale divided his work into three tracts, each with more than twenty lessons. He opposed Averroes, much like the French humanist Fabri Stapulensis (Jacques Lefevre, 1450? Étaples in Picardy-1536), who was greatly appreciated by Hvale.[201] Hvale on the other hand used quite a lot of Arabic literature. He agreed with Occam's (Ockham) theory of impetus as it was expanded by the nominalist Buridan, focusing primarily on the natural sciences of physiology, biology and medicine. Buridan was a rector of the University of Paris in 1327, and he was a canon in Arras in 1342. He denied Aristotle's claim that after the initial shock (impetus), further movement is enabled by the surrounding medium. According to Buridan, an impetus is enough, which he described as something

like the modern energy. The medium was not necessary for him, especially not for the movement in the universe, which he filled with the vacuum without shouting about it fromthe rooftops. He thus established the principle of inertia from the first Newtonian law, and even indicated the later concepts. However, for a long time Galileo used the word "impeto" or mobility both for the speed that the body acquired at a given time, and for the distance traveled on differently inclined planes within a given interval. Despite his enthusiasm over Buridan, Hvale did not fully accept his approval of a vacuum, which was rarely at that time anyway. Since its founding (1365), the University of Vienna has supported the nominalism of Buridan and Franciscan Ockham, a physicist known for his "Ockham's Razor." The opposite direction of the "realists" of Albert the Great and his student Tomas Aquinas, who was heavily represented in Terpin's catalog of books, allowed the vacuum to be an option in principle because they did not equate it with nothing.

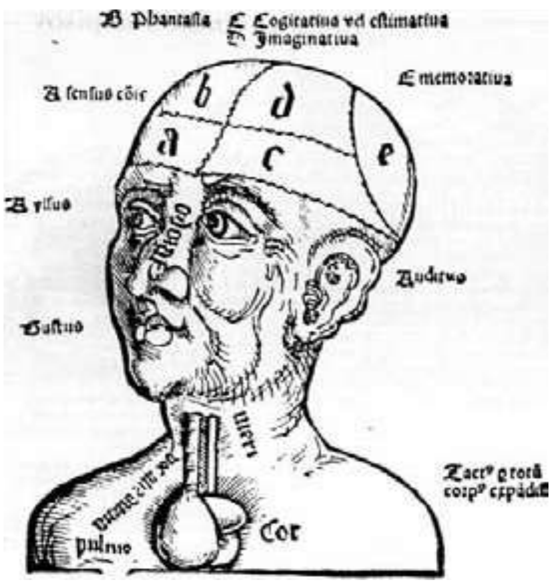

Figure 3-35: The head in the book of Hvale.

Hvale decorated his twelfth lesson of the first part with a picture of a bust of a man. Hvale focused on the individual parts of the skull and the esophagus, drawn as the visible part outside of the bust of a body. There, he painted a symbolic image of a human head with letters as signs of individual parts of the eye.[202] The problem of space, vacuum, and place was solved by Hvale's brief explanation of Aristotelian definitions of Albert the Great (Albertus Magnus, 1200-1280), whose books Terpin also catalogued. Despite of the otherwise modern humanistic approaches, Hvale accepted the scholastic Aristotle's space as a determinant of substance. This meant there was no room without substance. That is why Hvale rejected the existence of a vacuum three times: there is no empty space outside the world (of the Earth), it is not natural because of the horror vacui, nor is the vacuum in the material content of the bodies, such as in supposed pores.[203] The first claim that denied the vacuum in the universe was particularly questionable and many doubted it because of the apparently unimpeded movement of celestial bodies.

In the first lesson of the second part, Hvale described four ancient elements and sketched their connections with four human temperaments, four feelings, and the like.[204] The number four seemed to be something special to the humanist Hvale. In the sixth lesson of the second part, he described the dilution and condensation. The thinning was, of course, a way to a vacuum, which, however, was not entirely up to Hvale.

Besides Hvale, many other Slovene scholars taught in Vienna of Trubar's days. In 1464, at the University of Vienna as a magister of philosophical sciences, the Styrian Perger lectured on Euclid's geometry, optics and mathematics with astronomy, in which he interfered with vacuum issues. In the spring semester 1470/71 he was dean of the Viennese Faculty of Philosophy, and he was the rector of the entire university in winter semester.

In 1492 the Emperor Friderik III appointed Perger as his attorney at the University of Vienna; therefore, after Friderik's death in 1493, he had a magnificent speech as Chancellor of the new Emperor Maximilian I, who soon proved his support for the scientists of Perger's kinds. Up to 13. 10. 1500, Bernhard Perger kept his super-intendant's job until he was certainly sick. Styrian Perlah from the western edge of Slovenske Gorice[205] may not personally know his somewhat eastern compatriot Perger, but with their influences they almost followed each other at the University of Vienna and at the court of Emperor Maximilian I. Three years after Trubar's birth, in 1511, Perlah, entered the Viennese philosophical Faculty and after four years he got his title of Master under the influence of his compatriot Matija Hvale. Already as a student, Perlah began to copy and arrange foreign works that he mostly devoted to his patron, the Bishop of Vienna Jurij Sladkonja. Sladkonja was born in Ljubljana, which made him especially close to the great Styrian Perger. In the year before his death in the spring of 1522, Sladkonja allowed the Viennese St. Stefan preachers to advocate the new Reformation concepts,[206] which the other authorities soon canceled.

Perlah became a professor of medicine after his doctorate at the Viennese Faculty of Medicine in 1530. He made an analogue computer called Astrolabium Arithmeticum. His invention of Ptolemean Organum gave a good enough picture for observing of Mercury, which was only rarely possible before the invention of the telescope. The Latin translation of Perlah's German ephemeris for 1531, issued in 1530 in Vienna, was provided by Perlah's pupil, the Bela Krajina native Kukec. In 1535 he was a professor of mathematics and a procurator of students of Hungarian nationality at the University of Vienna, and in 1539 he became dean of the Viennese Faculty of Philosophy. Thus, the Slovenes Perlah and Kukec were the deans simultaneously in two of the four faculties of the Viennese University. Dr. Jakob Strauss continued with Perger's and Perlah's tradition of editing calendars. Jakob Strauss began his education in Budina's private school in Ljubljana. From 1552 to 1556, Strauss studied Philosophy at the Viennese University until his master's degree. In 1560 he completed his studies with answers to 144 questions, which also touched on the existence of a vacuum. He then went to the University of Padua before the Istrian Santorio and received a doctorate in medicine in 1565. In 1571 he became a doctor in Celje, and he occasionally treated his patients in Ptuj and Radgona. Trubar and Kepler as regional physicist and professor in Graz continued the tradition of publishing profitable calendars and prophecies in those areas after Perlach. This type of money was not provided solely with the support of a few superstitious rulers and noblemen. From Perger onwards, the cheap calendars were published even for a simple people, which was, of course, a great business.

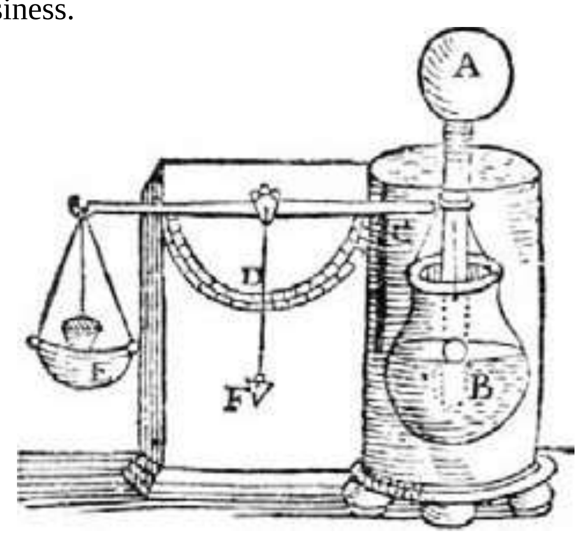

Figure 3-37: A sketch of air weighing in Harsdörffer’s book kept in Volf’s Library. The procedure was first performed by Koper native Santorio Santorio (Harsdörffer, 1651, 2: 365).

---

[205] There are some doubts about Perger’s Slavic background which relies only on scolding of Conrad Celtes (Celtis, 1459-1508) and are therefore doubted by Daniel Luger: *Humanismus und humanistische Schrift*, 2014, p. 200; Humanismus und humanistische Schrift in der Kanzlei Kaiser Friedrichs III (1440–1493) (MIÖG-Ergbd. 60, Wien 2016.

3.2.3.4 The Physician Santorio

Besides Vienna, Padua was also an important center of scholars of the Slovene genus. Many of the then educators and erudite were physicians, including Piran native Protestant Janez Krstnik Goineo and Koper native Ivan Bratti. Bratti was born in Koper according to his own narration in his main work, the Debate on New and Old Medicine. Bratti's contemporary from Koper was a physician and doctor Santorio, the son of the Friuli native nobleman and the noblewoman of Koper. After his initial schools in Koper and Venice, he completed his studies in Padua in 1582, and then he practiced at the Polish royal court, where the Capuchin Valeriano Magni independently carried out his own Torricellian experiment in Warsaw half a century later in 1646. The atmosphere at the Polish court was therefore favorable to vacuum experiments already at the time when Santorio first weighed the air to prove the air pressure. With this, he indirectly confirmed the possibility of a vacuum, which was later repeated by Otto Guericke with the help of the Prince of Ljubljana Janez Vajkard Auersperg. Between 1587-1599 Santorio became a doctor in Karlovac, which had just been built between 1578-1583. Santorio served the Croatian counts Krsto, Juraj and Nikola Zrinski. He then cured the illnesses in Venice as a member of the Galilean networks.

Between 1611-1624, Santorio was teaching medicine in Padua in accordance with his two six-year contracts instead of three-years-older Galileo, who went to Florentine court. After his retirement (1624), Santorio lived in Venice. In the commentary of the works of Arabic doctor Avicenna, Santorio immediately added the scale to Galileo's thermometer for medical measurements right after the start of his Paduan lectures.[207] In 1634, the third reprint of Santorio's medical book De Statica Medicina was published.[208] It was offered for sale by Mayr in Ljubljana in 1678.[209] With medical statics in the form of aphorisms, Santorio introduced a research of metabolism and other experiments in biological sciences. Santorio invented scales on a table to measure his own weight during his eating and drinking. Thus, he has proven a high proportion of secretion of matter through the human skin, which was unmeasurable by itself in those times. He determined the pressure and compiled a pulse gauge with a Galilean pendulum. His explanation of metabolism is often mentioned together with discovery of the blood circulation of his seventeen years younger Englishman Harvey, who also studied in Padua. Santorio's collected works (Opera omnia) were printed post-mortem in 1660.[210]

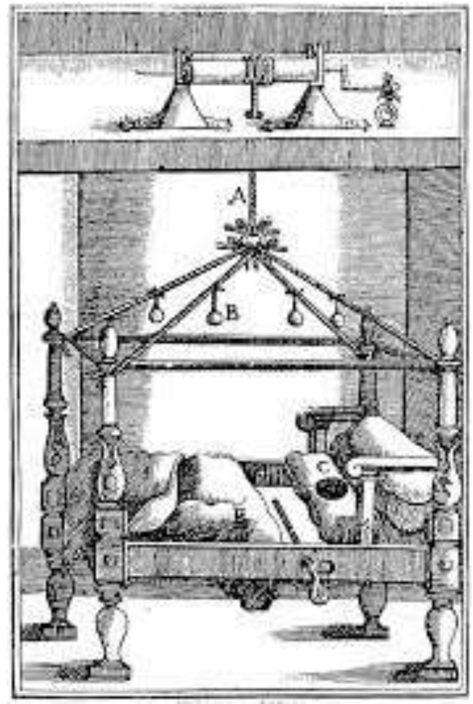

Figure 3-38: This was how Koper native Santorio weighted himself after an abundant meal to confirm the presumption of the passing of matter through the skin.

3.2.3.5 Frischlin's Vacuum in Siphons beneath Lake Cerknica

At the end of the Santorio's era, Frischlin became the first Ljubljana scientist of European reputation. He did not spend much more than two years in Ljubljana by Trubar's recommendation. In any case he placed Ljubljana on the map of scholars of the world.

Frischlin matriculated at the University of Tübingen on 12 November 1562, a year after Primož Trubar's

210 Dadić, 1994, 12, 237.

relocation to nearby Urach,[211] where Frischlin later ended his pursuits very sadly. In 1571, the Tübingen University was shut down due to the plague as Trubar[212] reported to the residents of Ljubljana. For seven years, Frischlin led the philosophical discussions of the future baccalaureates, which usually lasted for three hours. He even compiled an encyclopedia of physics, morality, astronomy, logic, and rhetoric for baccalaureates, as reported to the Senate of the University. In the autumn of 1574, Frischlin publicly questioned thirty-eight candidates; among them were three candidates for the degrees of baccalaureates. He asked questions about seven free arts, as usual.[213] He began with arithmetic, followed by music, geometry, Sun with the Moon, astronomy, problems of vision and light, and smelling with fragrances, as the last among human senses.[214] Vacuum-related questions were placed mainly in the second half of the defense. The milieu of Tubingen, as one of the leading Protestant universities, formulated the opinions about the vacuum of Frischlin, Kepler, as well as Trubar and almost all prominent Protestants in Ljubljana of those times.

Figure 3-39: Frischlin's portrait.

[214] Frischlin, 1598, 207, 210, 211, 213, 219, 224.

The first sight of the magnificent supernova was observed on 5 November 1572. The formidable spectacle caused great excitement in Europe. A powerful shining star, which suddenly emerged in the supposed vacuum of the universe, has sparked many guesses. Of course, Frischlin also did not forget to put his erudition on stage, and he immediately published his 831 verses in the following year (1573); he wrote that poem in November 1572. He addressed it to Wilhelm's brother, the Prince Friederich Würtenberg, and published it together with the accompanying letter and Maestlin's observations. The later Kepler’s teacher Maestlin was right then the second professor of mathematics in Tübingen, and with his observational astronomy, he complemented Frischlin's more philosophical approach. Obviously, at that time Frischlin and Maestlin were still in good relations.

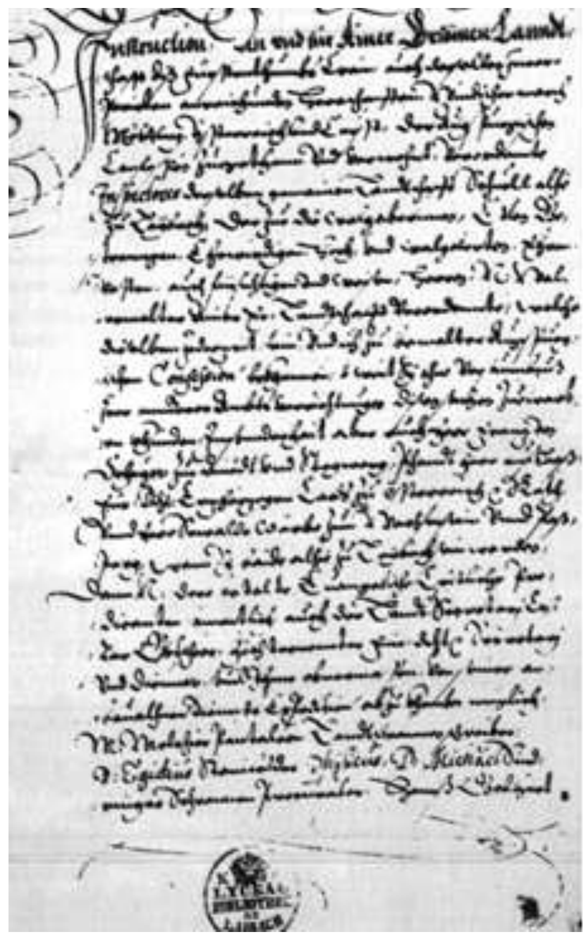

Figure 3-40: Frischlin's students of the fifth and fourth year in Ljubljana in 1583, where they also heard much about vacuum (ARS, Regional Estates General I, fasc. 98).

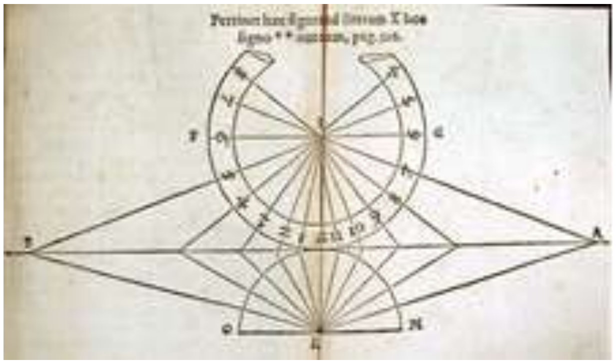

Figure 3-41: Frischlin's sketch of the zodiac when interpreting the variable speed of the Sun in a vacuum of space (Frischlin, 1586, 237)

The Carniolans also participated in the Württemberg debates about the supernova, as Primož Trubar preached for a while near Tübingen in Urach, and his patron the baron Ivan Ungnad was leading a print shop there until his death. On March 1, 1583, Frischlin wrote to Trubar in Derendingen. A few weeks later, on 3 April 1582, Dr. Jakob Andreae in Tübingen and Primož Trubar in Derendingen were searching for the successor of retired Ljubljana school rector Adam Bohorič. In June 1582, the Duke allowed Frischlin to accept the position of the Ljubljana Rector.[215]

On 24 June 1582, Frischlin sailed on the Danube and Mura river through Vienna and Graz, as Frischlin traveled to Ljubljana. In June, he arrived without a family and took over the position of the rector of the school. In his Ljubljana era, Frischlin published two Latin textbooks in Venice, but he was not allowed to use them in his class. Since he published the book without the permission of Carniolan provincial Estates General, he was questioned about his motives. This was another Frischlin's displeasure while his wife was constantly complaining about her Ljubljana whereabouts. He had resigned, which proved to be a grave mistake.

Frischlin has certainly found many educated men in Ljubljana. In Ljubljana, the scientific thought was supported by the Ljubljana printer Mandelc together with the astronomer-doctor Strauss. On March 1, 1583, Frischlin wrote against the Duke of Wirtenberg and even against Primož Trubar. Frischlin had always his conflicts with the Carniolan school inspector, the head of the Carniolan schools Juraj Dalmatin, although he supported the printing of Dalmatin's translation of the Bible upon his arrival in Ljubljana. In 1586, Primož Trubar was buried by Frischlin's opponent the chancellor and the city provost J. Andreae in Derendingen. The tombstone in the verses, which we read today in the Church in Derendingen, was compiled in Greek and Latin by Martin Crusius, who was the worst enemy of Frischlin.

Frischlin was sufficiently educated to understand the working of underground pipes in a perforated earth through which the water penetrated the Lake of Cerknica to drain from the dried bottom later. Thus, he was among the first to investigate Lake Cerknica and vacuum was involved in his description. He published a Latin-written poem about Cerknica Lake, which was reprinted by Valvasor. Anton Urbas partly translated it into German language three centuries later. Valvasor devoted to Frischlin a whole chapter of eight pages, of course,[216] with a special emphasis on his Ljubljana period. Frischlin personally looked at Lake Cerknica at least in winter and witnessed successful fishing or even ducks that were supposedly driven by winter torrents. Even more important was Frischlin's idea of underground siphons (siphonibus), which also became part of Valvasor's description.[217] Of course, Frischlin was the best Latin poet of his time. The term siphonibus could also be used in the sense of a waterjet or tube, and not only in the modern sense of the siphon that presupposes an intermediate vacuum. Frischlin might have used Žiga Herberstein's earlier description of Cerknica Lake. Valvasor's Latin language ability was much weaker and did not go beyond the high school level, so that he was probably unaware of all aspects of Frischlin's Latin poem. Frischlin's siphon theory influenced Edward Brown in 1669, who also wrote about hidden collecting lakes in Javorniki, about siphons under the visible Cerknica lake and the alleged underground lake. Similarly, Valvasor and Steinberg conceived the infinite sequence of siphons under Javornik. Only Gruber successfully criticized that siphon theory. Gruber did not accept Steinberg's description of Cerknica Lake as a system of interconnected

[215] Röckelein, Bumiller, 1990, 136.

[216] Valvasor, 1971 *Die Ehre*, 2 (7): 450, 445-452..

[217] Valvasor, 1977, 108.

siphons. Gruber was one of the pioneers in the description of Cerknica Lake and Planinsko polje as he knew that in the riverbed and lakes there is a balance between the flow of precipitation from the atmosphere and the runoff of the river towards the sea.

Frischlin wrote his astronomy in the form of questions and answers, like Kepler did later in his Epitome astronomia Copernicana, which was an interesting pedagogic approach. The Protestant Frischlin unanimously bravely supported the papal calendar reform in Ljubljana, but, of course, he had the support of the ruler in Graz. The Habsburg monarchy adopted the Gregorian calendar in 1584. Later, the Gregorian calendar was also supported by the Protestant Kepler, which was one of the reasons why he was not able to get a job in Tübingen.

Frischlin described the similarity between humans and planets and separated observational astronomy from astrology. He was interested in the color of the supernova fire, which, despite Maestlin's interpretation, Frischlin still identified with comets.[218] Frischlin certainly respectfully noted Copernicus's ideas about the motion of the sky. In his explanations of the heat of the Sun, Frischlin quoted the alchemical work of the Twelve Keys, published by the alleged German Benedictine Monk Basilius Valentinus. Basilius's book was even used by Newton. According to Basilius, Frischlin summed up the correct claim that the heat of the Sun promotes growth on Earth, but it does not cause it. Frischlin read the records of Menelus of Alexandria about the movement of stars and a Muslim researcher from the 9th century Albategnus (Albategnius) with the Arabic name Abu Abdullah Muhammad Ibn Jabir ibn Sinan al-Battanial-Harrani. Frischlin accepted Pliny's and Ptolemy's opinion about the circulation of Venus and Mercury around earth beneath the sun in contrast to Plato or Aristotle. Frischlin based his opinions about the moving of planets through a vacuum mostly on Purbach's Viennese book on the motion of the eight spheres,[219] and thus approached Hvale's Viennese conception of space and vacuum. Frischlin supported Aristotle's philosophy of nature and did not recognize the vacuum, just like Hvale.

A quarter of a century after listening to Frischlin's Tubingen astronomical lectures, Kepler's teacher Maestlin, now an already famous astronomer, rejected Frischlin's astronomy (1586) in his report to the Tubingen University. His former professor Frischlin utterly poorly mastered astronomical and mathematical terms, as Maestlin noted in his letter handed over to the duke on 18. 1. 1586. A few months before Trubar's death in nearby Derendingen, Maestlin found a mathematical error in Frischlin's data, and he even quoted the Bible in proof of Frischlin's misconceptions about the appearance of the Sun and Moon.[220]

Maestlin did not like Frischlin's rejection of astrology and "poetic" doubt about the use of mathematics in astronomy. Above all, Maestlin did not approve Frischlin's reception of the Gregorian Papal calendar because Maestlin was the greatest critic of Papal reform. The Copernican fan Maestlin refused Frischlin's sharp criticism of Copernicus, which was not insignificant in Maestlin's eyes. Like his student Kepler, Maestlin saw in astrology, among other things, a natural source of earnings for professional astronomers, which he was not willing to abandon. So, Maestlin critique of Frischlin had more economic than scientific background.

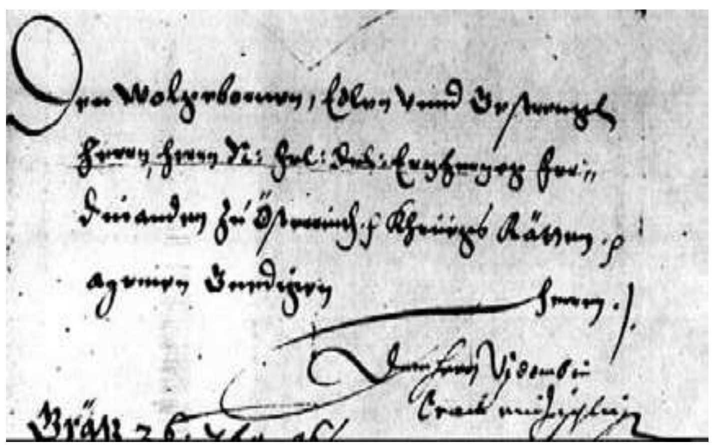

Figure 3-42: The Ljubljana Fireball of 1596: the cover of the ruler's decree signed in then capital, Graz, on October 7, 1596 (SI_AS, Archives of Slovenia, Vicedom's archive, box 181, fasc. I / 102, IX-2, p. 4).

A member of the Academy of the United (St. Dizma) and Terpin's successor in the position of a diocese vicar, Carl Peer, kept Frischlin's Astronomy (1586) in solid leather coverings among Peer’s 1022 works bind in 2019 volumes. Peer's copy of Frischlin's work is in NUK today, while the Semeniška (Seminary) Library have inherited several other treasures from Peer's collection.

3.2.3.6 Ljubljana Design of Fireball Resembling later Steam Engines

In Trubar’s days in Ljubljana, the experts did not only witness an advanced theory, but also a bunch of practical inventions, the ancestors of steam engines. Shortly after Trubar's death, on 20 September 1596 Gregor Corissa from Ljubljana sent to the emperor Ferdinand and to a viceroy in Ljubljana an extraordinary letter on three pages about the invention of fireball of Joachim Turekh, who was probably also a citizen of Ljubljana.[221] At the same time, he addressed the letter to the four members of the chamber. The fireball should be used at 100 miles of distance and could be even set to start and operate after 24 hours; a kind of medieval timebomb. It produced a powerful fire. Turekh used Heron's ancient findings about vacuum, air pressure and steam engines. He handed over his invention to Corissa, who wanted to show Turekh's ideas to the archduke Ferdinand II. On 26 September 1596 he sent another letter, and the archduke answered him on 7 October 1596.

Figure 3-43: Kepler's memorial plaque at the Paradeishof number 1 building in Graz, where he taught (Photo: Bruno Besser, 2005).

3.2.3.7 Kepler in Prekmurje

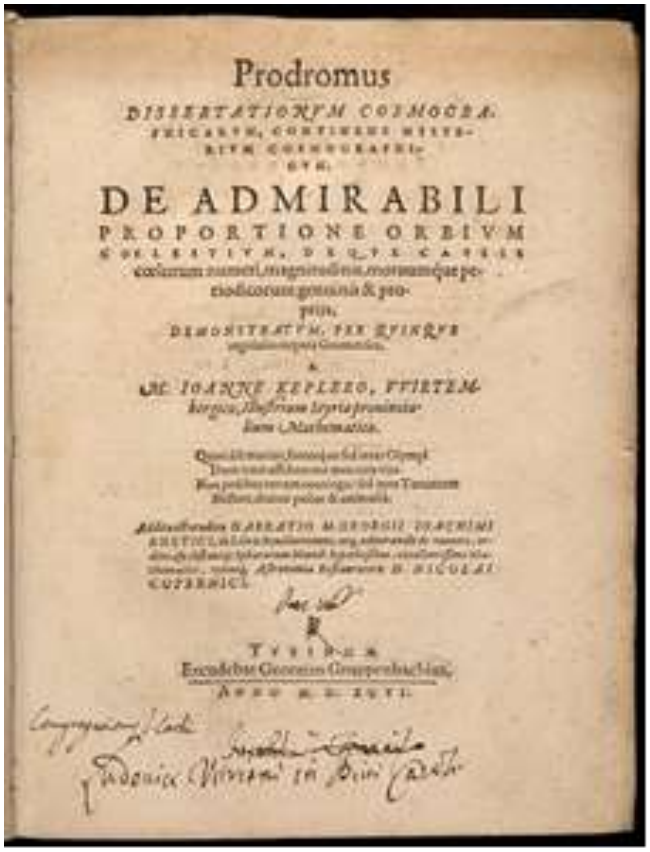
Frischlin's younger Tubingen colleague Kepler as a Styrian provincial mathematician left a deep trace in the development of science in today's Styria. How deep? What was his influence on thinking about the vacuum in Inner Austria?

The most important Estates General’s Protestant school (Stiftsschule) in the Habsburg hereditary countries worked in Graz from 1 June 1574 to 1602. Kepler taught there from 11 April 1594 to 28 September 1597. Until 1600, he continued with lessons, practically without students.[222] After the reformed school order of 1594, they taught mathematics and physics in the last fourth public class (quarta classis, quae publica dicta) in Graz and Ljubljana.[223]

On 11th/21st April 1594, Kepler came to Graz, although he had not finished his studies in Tübingen, which he should have done in the summer of 1594. Kepler's friend, the Slovenian Protestant Sigmund Friderik Herberstein, was by the funny old fashion in charge of "chopping meat at the court". In September 1595, Kepler mildly mocked about this Herberstein's lucrative job which used to nurse such funny medieval obsolete name. Herberstein was born on Šahenturn in today's Gornja Radgona on Prešerenova Street no. 1 shortly after the first edition of Copernicus’ book. Herberstein was among the first readers of Kepler’s Mystery together with Maestlin, professors and students of Tübingen University, Styrian nobles, Kepler supporters, Galileo and Tycho Brahe.[224] Kepler wrote the Mystery from July 1595 to January 1596 while he was consulting with Maestlin. In February 1596, Kepler went to publish his Mysteries in Tübingen, and at the same time he prepared his wedding with a twenty-year-old Protestant Barbara Müller from Graz, a double widow with one daughter. As a professional astronomer Kepler first published in his Mysteries a convincing geometric interpretation of the Copernican theory of motion of celestial bodies in a vacuum, to which just this Keplerian work gave the right swing; so far, only a dozen astronomers

[222] Belii, 1971, 30, 260-261.
[223] Vidmar, 2000, 10, 24.
[224] Kepler, 1984, 240, 242, XXIV.

supported it. Kepler had corresponded with Galileo, even if he did not agree with all Galileo's descriptions of vacuum.



Prodromus

DISSERTATIONUM COSMOGRAPHICARUM, CONTINENS MYSTERIUM COSMOGRAPHICUM,

DE ADMIRABILI PROPORTIONE ORBIUM COELESTIUM

DEMONSTRATUM, PER QUINQUE

M. IOANNE KEPLERO, VVIRTEMBERGICO

Figure 3-44: Title page of Kepler's Mysterium Cosmographicum from the year 1596 issued by the same Tübingen printer Georg Gruppenbach who released Trubar's translation in next year.

Trubar and Kepler often met as they had the same publisher Georgius Gruppenbachius in Tubingen. Kepler inserted several geometric images into the text of the Mystery. He connected the orbits of the planets to the five familiar known characters. He placed the cube between Saturn and Jupiter, and the tetrahedron was between Jupiter and Mars. Even in Harmonices Mundi (1619), Kepler used the regular 3-dimensional geometrical shapes to delineate the orbits of individual planets, although in the meantime he found that the model cannot be completely accurate. That great idea was related to Kepler's thoughts about the symmetry of crystals published in his Prague observations of the first snowflakes in the new year of 1611. He thought about the surfaces and crystalline forms with the metal compounds themselves, thus forming alchemical connections between planets and metals that are still present in the name of Mercury.

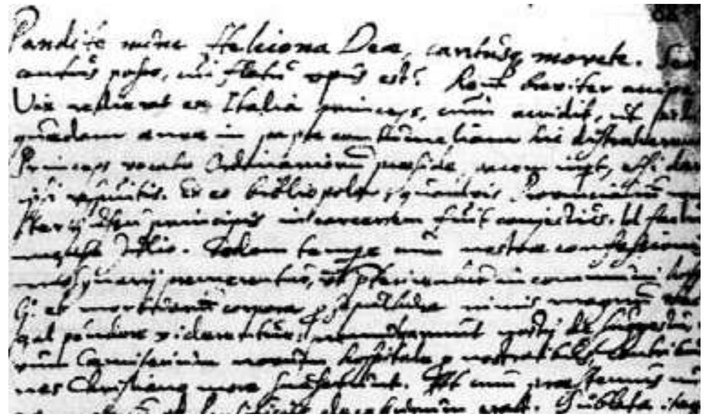


Figure 3-45: Kepler's letter from Graz, mailed on 8. 12. 1598 to his teacher Maestlin to Tübingen with a report about staying in Petany (Petanjci) in his 40th line (Stuttgart, Württemberg Regional Library, Code Math Foll 14a, pages 78-86).

In Kepler's youth, the era of Catholic tolerance towards Protestant religions was abandoned for many decades to come. On 23 September 1598 the newly powered wind was announced by Archduke Ferdinand II, who commanded all Protestant pastors and teachers to leave Graz in six days. The measure seemed impossible to everyone at first. On September 28, 1598, he ordered them to leave Graz by the sunset. They should leave Styria and other areas of inner Austria in a few days or face their death penalty. In a month (October 29, 1598), the same cruel measure surprised the Ljubljana preachers and lecturers. Together with about forty other teachers and pastors from Graz and Radgona, Kepler headed towards Zrinski's estates in Varaždin. The violence was mitigated so that they gave farewell with their last salary pocketed. The exiled victims soon found their shelter in a castle on the nearby estate of Count Nádasdy in Petanjci in the royal Hungarian Prekmurje, just a few miles east of Bad Radkersburg (Radgona). They used the church in the nearby village Tišina (Silence). They were the first Protestants in those now Slovenian settlements. Since they did not know the Slovene language of the locals, it was difficult for them to purchase food, which was therefore imported from Radgona. Kepler retained his good relations with the Bavarian Catholic Chancellor and the Graz based Jesuits. Therefore, he was able to return to Graz after a month, while the rest of his company continued to live in Prekmurje. Kepler was particularly helped by his service of regional mathematician-physicist, which was not dependent on political circumstances related to religion, so he had his unique chance of returning after one month of exile. Kepler's "trip" to Prekmurje further contributed to the resurgence of his theories of vacuum and crystal surfaces in Slovenian places, where many clever readers bought his works. He published his ideas on crystal surfaces in Slavic Prague immediately after returning from the Slavic Slovenian areas, so that he must have at least somehow designed them during his stay in Prekmurje.

3.2.3.8 Concluding Remarks on Vacuum of Trubar's Days

The special kind of circumstances before the start of the Counter-Reformation in the Inner Austrian capitals lead the flower of Tübingen scholars into Inner Austria: Frischlin went to Ljubljana, Megiser to Klagenfurt and Kepler to Graz.[225]

Tubingen thus did not only provide Slovenes with Trubar's Protestant press in Slovenian and other languages, but also with fruitful newly designed ideas about vacuum, crystals and surfaces. Both bore its fruits in the next generation, when Ljubljana prince Vajkard Janez Auersperg as a youngster converted from Protestant to Catholic faith to become the main Guericke's assistant in vacuum experiments. Janez's ancestors were widespread supporters of Trubar, who was the subject of Janez's grandfather, former Paduan student Baron Krištof Auersperg, a resident envoy at the National Assembly in Augsburg in 1582.

Only one year after Auersperg's participation in Guericke's vacuum experiments in Regensburg the Diocesan vicar Upper Carniolan (Gorenjec) native Filip Terpin (Trpin, * 1603 or 1604 Selca above Škofja Loka; † 23. 6. 1683 Šmartno by Kranj) also listed technical, military and natural science-mathematical books on the conclusion of his division of World History books. Such arrangement was at that time in the habit.

[225] Röckelein, Bumiller, 1990, 107.

3.3 Conclusion

The evolution of vacuum techniques by the invention of the barometer and vacuum pump can only be compared with the century later installations

following the breaking vacuum cathode ray tube experiments after Geissler achieved a repeated Torricellian mercury experiment in a glass tube in 1857. He reached the pressure of 1 mbar in barometric mercury tube after the Plücker's Bonn order. Half of a century later, a new upheaval was followed, when this kind of fun toy was suddenly used in the advanced science of emerging quantum mechanics. Today's surprises are the result of their technological use. Despite of the subsequent sequence of great achievements, it seems that the Slovenians most likely contributed to the progress at the very beginning by Auersperg's helping Guericke's experiments and, consequently, with the growing interest in the vacuum among Carniolans, which is proven by unexpectedly many early discussions about the vacuum in libraries in then Slovenian areas. Therefore, the writer of these lines would have imagined that Janez Vajkard Auersperg, as a Guericke’s assistant, should become part of the public image of the Society for the Vacuum Technology of Slovenia, since Guericke in his book acknowledged Auersperg's share in their experimental success,[226] and it is unlikely that in the Slovenian areas there will be another such success anywhere soon. To this end, we propose the appealing version of the sign of the Society for Vacuum Technology of Slovenia, which can further emphasize the Ljubljana share in the progress of vacuum techniques on a global scale.

II. Fugue: Pumping & Measuring of Vacuum Related New Materials

4 Early Metrology: Barometers & Manometers

4.1 Experiences with Vacuum in the Middle of the 17th Century: the First Uses of Vacuum in Barometer

4.1.1 Galileo's Disciples

Gilbert was one of the first modern experimental researchers and has therefore successfully treated the unpredictable English perpetual virgin queen Elizabeth. Unfortunately, he was convinced that nature avoided the vacuum; although, on the other hand, he knew that the vacuum does not hinder the motion of the bodies above the Earth's atmosphere. Two differently imagined types of empty were still battling ghosts. Galileo challenged Aristotelian authority with an experimental approach to science. According to Aristotle, the movement was focused on the balance that was defined by the characteristics of the body. The speed of movement decreases with increasing environmental density. Galileo summed up the concept of acceleration by Strato of Lampsacus. He distinguished the concept of vacuum from metaphysics and attributed physical properties to it, such as zero density and viscosity. In the first day of talks on two new sciences, Galileo's Sagredo proved the final speed of bodies in a vacuum. So, Aristotle made a mess. Galileo communicated two novelties:

1) In the vicinity of Earth all bodies fall with the same acceleration; the substance in the surrounding area obstacles their free falls.

2) The vacuum is a substance with zero density and zero viscosity.

Galileo's vacuum was described as the extreme example of the lowest-density environment. This avoided Aristotle's fear of the emptiness, which Galileo put on the funny tongue to his simple hero Simplicius with the assumption that "the empty space itself opposes its own creation, which is not in accordance with the supposed economy of natural phenomena."[227]

Galilei used a new concept of "microscopic voids in matter" to avoid a direct dispute with Aristotle's deflection of the vacuum. He attributed these to physical properties and thus introduced the emptiness into physics through the back door. The philosophical description of the empty was necessary for Galileo's contemporaries to undertake research into the vacuum. For a long time, they knew the primitive ways of pumping. Their improvement and systematic exploration only flourished after Galileo's reflection was based on such a practice. The theory of vacuum initially led experiments, but soon experiments with powerful steps overtook their interpreters. The emptied voids become a driver of progress. Galileo's pupils did not use air pumps, although with it, the ancient Greeks had pumped flutes in their musical instruments. Water pumps were known in ancient Alexandria and in the mines of ancient Rome. The famous Roman engineer Vitruvius described them; he was followed by Agricola in his famous book on metals, which was purchased in Ljubljana in 1678. With the pumps, a vacuum of 0.33 bar (250 torr) was obtained in the 16th century. The constructors did not know anything about such exact results as they had no proper tools to measure the pressure. Galileo tried to estimate the force needed to create a vacuum. The problem connected pumping of water vertically upward with Archimedes' screw and with water pumps. Miners told Galileo that the height cannot exceed 34 or 35 feet or 18 elbows, which is todays 10 m. Thus, the senator's son Giovanni Battista Baliani (1582 Genova-1666) unsuccessfully constructed the siphon in Genoa in 1630.

---

[227] Galilei, 1964, 124–125.

Evangelista Torricelli was born in Faenza south of Bologna, where he graduated the Jesuit college After studying at the University of Rome, Torricelli became Galileo's secretary and successor in Florence.

Evangelista Torricelli (*1608; † 1647) [228]

In the 17th century, technological problems were solved with specially prepared experiments. Berti set up an adapted "pump" in front of his house in Rome in 1640, while he had a direct influence on Galileo's disciples.[229] Berti's device was basically a water barometer, but he still had to wait for the correct explanation.[230] He filled his 10 m high lead tube with water and connected its open end with the collector. He did not manage to show persuasive that the emptied space does not translate the ringing from its interior, which would convince the contemporaries of the existence of a vacuum. He was assisted by the Jesuits Zucchi and Kircher,[231] as well as Torricelli along with them. Torricelli happened to be in Rome at the time, as all the roads lead to Rome. They all admired the experiment, but at the same time each of them offered his different explanation of the results. As much people, so many opinions. At that time, in 1639/40, Kircher began to teach mathematics at the College of Rome. He continued with the lessons between 1644 and 1646, and he later set up a museum with a vacuum pump and other unusual devices in his premises of Roman college. His collection became one of the wonders of the eternal city.

Kircher's pupil, the German Jesuit Schott, reported all about Berti's experiment in a book that was soon on sale in Ljubljana.[232] Thus, Slovenian ancestors in today's Slovene countries quickly learned about the first experiments with a vacuum (Fig. 4-1).

Galilei died on January 1, 1642, almost 78 years old. Torricelli's barometric experiment was designed very likely only in the spring of 1644, and not a year earlier. Torricelli's passed his instructions to another Galilean pupil and founder of the Florentine Academy of Cimento, Viviani.[233]

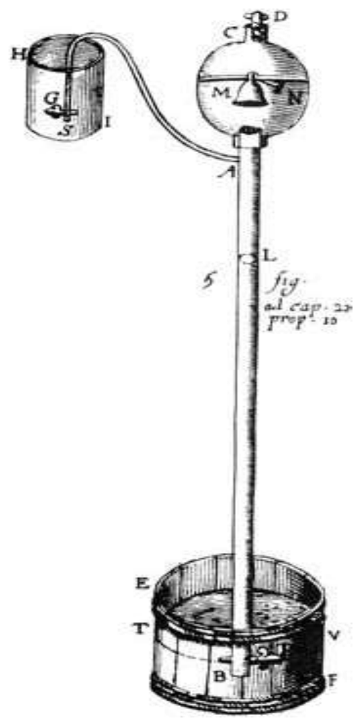

Figure 4-1: Berti's vacuum device[234]

The experimental trial was supposedly completed before 13th June 1644, when Torricelli described it in Florence in a letter to the future Cardinal Michelangelo Ricci (1619 Rome-1681 Rome). Ricci was a Roman student of Galileo's student Benedetto Castelli (1578-1643). Torricelli called his experimenters all the time with the pronoun "we",

which certainly included at least Viviani. He used a two "braccia" (1.2 m) long glass container. He did not report about the thickness of the glass and the width of the tube. The Venetian masters, who greatly surpassed all contemporaries, could have designed such a vessel. Thus, in the middle of the 17th century, Colbert had to trick Venetian authorities to steal their secrets of making mirrors for the needs of the French court.The closed top of Torricelli's tube was expanded into a pumpkin, as was usual with the then Italian thermoscopes, while the Dutch tubes were mostly made in the form of a letter J. In 1624 the term thermometer was first used by the French Jesuit Jean Leurechon (1591 Bar-le-Duc-1670 Pont-à-Mousson) or by his local printer engraver of University of Pont-à-Mousson Jean Appier Hanzelet (1596-1647) in their Les Récréationes Mathématiques[235] published under the pseudonym Hendrik van Etten. Ozanam, Schwenter and many others used the similartitles few years later. Likewise, the extension pipe at the closed top was drawn by the supposed Jesuitical fan Marcus Marci in his letter mailed from Prague to Kircher on January 25, 1642. Kircher himself proposed the use of mercury in a thermoscope because he knew about its production in the Carniolan Idrija. Thus, all elements of the Torricellian experiment were known even before it was placed. Nonetheless, no one in Italy has disputed Torricelli's priorities. Consequently, the Jesuit Fabri claimed that he had made a similar experiment at the Jesuit College of St. Trinity in Lyon around the year 1641[236] while Magni demanded his own championship for his experiments in Warsaw.

Torricelli reported: "... We filled (a vessel) with mercury. We tightened its mouth with a finger and turned it into a mercury vessel C. It showed up its the emptiness, and nothing has happened in the empty part of the container. The length AD has always been filled to the height of one and a quarter of Braccia and one inch (a total of 29.75 inches or 760 cm). To show that the vessel is completely empty, we filled the container below it with water to the point D. The vessel was slowly rising, and when water reached its mouth, we saw a drop of mercury at the neck (of a vessel). The great force filled the container with water up to the mark E. During the experiments, the AE container was empty, and the heavy mercury was held in the neck noted as the AD.

The force, which holds the mercury upright and prevents its fall back into the container against its nature, is presumably in the AE container, and it originates either from a vacuum or from a strong diluted mercury. For myself, I suppose that the force is external and that it comes from the outside. The surface of the liquid in the vessel is pressurized by a mass of 50 miles high air. Should we then be surprised that the mercury in the CE container, where it is not pushed nor hauled, because there is nothing there, rises to such a level that it comes into balance with the outer air that pressures it. The water will rise to almost 18 braccia (10 m) in a similar but much longer container. This is much higher than mercury rises, as mercury is heavier than water, but it must strike a balance with the same pressure that presses on both of the liquids..."

Figure 4-2: Torricellian mercury barometer[237]

[235] Among its many reprints by Claude Prost in 1642.
[236] Gorman, 1994, 12, 17.
[237] Wolff, 1758.

Torricelli followed his teacher Galileo's turning around of ancient questions, heads upside down. Instead of exploring how the "fear of emptiness" drags the column of Idrija mercury upwards in the closed side of the U-tube, he explained that it is pushed up by the air pressure from the open side of the U-tube. By changing the question, "fear of emptiness" gradually lost its meaning as it was replaced by the term of (reduced) air pressure (Figure 4.2).

Upon returning from Florence and Rome, in the spring of 1645, Descartes' former classmate Mersenne reported Torricelli's success in Paris.

In 1645, the grand duke Cosimo II's (1590-1621) son, the art-collector Cardinal Giovanni Carlo de'Medici (1611-1663) presented Torricelli's experiment to Kircher and other Roman Jesuits, as we read in five years later Kircher's Report.[238]

On 25 October 1647, Torricelli suddenly died of fever. About a month later, on December 13, 1647, Descartes reported to Mersenne in Paris that he set a Torricelli's type barometer.[239]

Despite the Thirty Years' War, scientific news spread even in the burning German countries. As early as 1646, the Capuchin Magni set up the similar Torricellian experiment at Ladislaus and Louise-Marie's courts in Warsaw. The Queen's Secretary, Noyers, immediately informed the French physicists about the event. The Polish court was very enthusiastic about science, because the queen brought to the palace one of the first models of Pascal's computer and wrote a letter to Kircher. Researchers from the Ujazdów Observatory near Warsaw collaborated with Parisian astronomers Boullualdi, Pierre Petit (1594-1677) and Adrien Auzout (1630-1691). In 1663 Auzout demonstrated the use of a telescope without a tube,[240] and later investigated the vacuum.

The last ruler of the Vasa dynasty, Jan Kazimierz, was also interested in science. Before the marriage with his half-brother Ladislaus's widow, the energetic Louise-Marie (Maria Ludwika), he was a cardinal and Jesuit; after his resignation from the Polish throne, he preferred to live in the worldly France. In 1654, Magni described his experiment to Guericke, prince Auersperg and other curious people at the National Assembly in Regensburg. Guericke's father was a member of the Polish royal court during his young years; so, he knew the situation in Warsaw well. The Regensburg audience did not fully believe Magni, as they have already heard something about Torricelli's and Viviani's experiments. After arguing, Magni admitted with his heavy heart Torricellian priority.[241]

Magni first described in detail the passage of light through the air and through a vacuum.[242] As a Capuchin, he was an unpleasant interlocutor to any Jesuit, especially with his sharp criticism of Aristotelian opposition to the vacuum. A magnificent Magni's critique of Aristotle's rejection of the existence of a vacuum was the worst challenge to the peripatetic guys of that time.

While continuing disputes with scholastic annoyed him, Magni found himself in Vienna. He was at the height of the path of life, and he tried to get even the cardinal hat. Of course, Auersperg would rather see a cardinal hat on his own head in those windy days; therefore, he did not support his old acquaintance Magni. He did not become too angry when the Pope[243] issued an order for arrest of Magni to bring Magni from Vienna to Rome after the advice of the Jesuits in 1661.[244] Magni's ideas remained a lasting thorn in the heels of all the advocates of Aristotle's science. The grandson of Auersperg's tax collector Anton Erberg, along with other Carniolan Jesuits, vehemently criticized the long-dead Magni's description of the vacuum even a century later.

4.1.2 Pascal for the Frenchmen

Pascal investigated the air pressure between October 1646 and April 1652. First, Petit reported on Torricelli's experiment to the family of Pascal in Rouen. Blaise Pascal repeated an experiment with the help of his father Etienne, Petit and their neighboring glassblowers. With the pump and

243 Aleksander VII, the Pope between 1655–1667.
244 Gorman, 1994, 19, 21.

according to the Torricellian method, they proved that mercury cannot be brought above the height of two feet, three inches and five lines. The water could be pumped much higher, up to 31 feet, and the oil up to 34 feet. The results were in the ratio of then available values of the density of those three liquids. Pascal immediately publicly exhibited experiments with communicating vessels and Torricelli vacuum over oil, water and red wine in front a glasswork shop in Rouen. Especially the latter was heavily cheered by passers-by. Blaise Pascal also investigated the pressure above water and wine in over 12 m long sailed containers. He proved that the vapor pressure over water or wine which evaporates faster does not affect the height of the column of the liquid in the tube. One of the demonstrations was seen by 500 knowledgeable and most of all thirsty neighbors.

On 23. 9. 1647, Descartes visited Blaise Pascal in Paris where Blaise's sister Jacqueline nursed him during his illness. At the first meeting, many friends and admirers were gathered. In the continuation of the conversation, the opinion of the sick Pascal was represented by mathematician Roberval. A sharp exchange of views ended the next morning with Descartes' visit to Pascal, who then probably imagined his famous measurements of heights with a barometer.

Because of Magni's demands for priority, Pascal hurried next month with his publication of New experiments with Emptiness. At the same time, he wrote a preface to his book about the vacuum, from which only parts were preserved.

The Jesuit Noël urgently sent his criticism to Blaise. He was a respected Rector of the College of Clermont (later Louis le Grand) and former Descartes' Professor of Philosophy at Le Fleché College.

On 29. 10. 1647 Pascal answered Noël that the space above the column of mercury is empty, because we can hardly imagine an invisible substance, although we can invent it. Pascal's thought sounds nice even for today's time:[245] "... the empty space is in the middle between matter and nothing."

[245] Sparnaay, 1992 10, 14, 15.

So, the vacuum is not a mere nonsense, and it is not clearly a nothing. In January 1648, Noël supported Aristotle's opinion in the book "Fullness of the empty". Blaise Pascal refused to answer him but described his position next month in a letter to Jacques le Pailleur. A further controversy with Noël angrily interrupted Pascal's father Etienne, as Blaise felt that Noël "changed his views more quickly than he himself could answer." In the Latin translation of his book, Noël later gave the recognition of the experiments of an ever-famous Pascal.

At the same time, the Englishman Hobbes wrote to Mersenne that Noël's experiments were not enough. But Hobbes, like Noël, was also a "plenist." He did not believe in the existence of a vacuum and preferred to claim that the "invisible substance" remains after pumping. His emptiness seemed a contradiction by itself; but this did not bother the convinced "vacuists", among them the French priest Gassendi, the professor of mathematics and astronomy at the Royal College of Paris since 25. 2. 1645.

In 1648, Hobbes wrote in French language to Mersenne, just before leaving Saint-Germain. He claimed that with Torricelli's experiment only a part of the air was removed; a tiny substance remains, like the passage of smoke through the water. Pascal responded to Hobbes's criticisms with a humiliating exclamation: "Hobbes, who knows this name in France?" The question was extremely offensive, as Hobbes lived in Paris between 1635 and 1640, and then returned to England. He subsequently participated in vacuum experiments in Paris and reported them to England in the spring of 1648.[246]

On November 15, 1647, from Paris, Pascal wrote to the Judge Périer, the husband of his older sister Gilberte (1620–1668). Blaise asked him to measure a supposed change of lengths of about 4 kg of mercury in a barometer at the height of 1465 m of the Puy-de-Dôme mountain near Pascal's Clermont-Ferrand birthplace in the Auvergne region, 150 km west of Lyon. Périer should compare his result with the measurement at the foot of the mountain. Only ten months later, on 19 September 1648, Périer and his companions carried out several measurements.

[246] Bernhardt, 1993, 229–239; Schaffer, Schaffer, 1993, 83, 86–87, 122.

For companions and witnesses, he took esteemed folks from the city of Clermont: The Abbot Bannier (Boniere) of the Minim (Minime) religious order monks, the canon of the Clermont cathedral church (*Cathédrale Notre-Dame-de-l'Assomption de Clermont-Ferrand*) Mosnier (Monière), the councilors of the court of Aides La Ville (Lavaille) and Begon (Begonn), and the doctor La Porte (Laporte) as professor of medicine in Clermont. At 8 am in the monastery garden at the foot of the hill, in three experiments with two identical barometers, the same height of the mercury column was measured. The result was 66 cm each time.[247] Then one of the two pipes filled with mercury was brought to nearly a kilometer[248] higher peak of the Puy-de-Dôme. There they measured by 3 inches and a half-line (8 cm) shorter column. The experiment was repeated five times in different suitable places and under different conditions: in the shelter and in the open, in good pleasant weather, in the rain and in the fog. The result was always the same: 23 points and 2 lines (58 cm). On their way back, they measured 25 points (62.5 cm) in the lower place "slightly above the monastery gardens" of the église Saint-Pierre-des-Minimes.

When they returned to the monastery garden, the Father of Minim religious order Chastin (Chastain) reported that the level of mercury in U-tube stored there was all the time on the same level, although the weather was changing with the wind, rain and fog several times. Périer then the elevation of mercury in the tube that he caried with him to the top several times. Each time, he got 26 points and 3.5 lines, which is today 66 cm.

Périer described his experiment in the garden and on the hill to the Oratorian priest de la Marc (abbot Mare); the next day he submitted a measurement at the top of the Notre-Dame-de-Clermont cathedral church tower, which was 27 toise (fathoms), 53 m above the garden. As they climbed the belfry, the mercury column dropped there by 2.5 lines (5.6 mm). The result was somehow disappointing; unfortunately, it was too late to find that heavy and awkward mercury barometers do not even have to be carried at the high Puy-de-Dôme, as Blaise's ideas could be easily proved on the bell tower of the nearby church. On 19. 9. 1648 Périer reported to Blaise about the experiment and submitted mercury column measurements for every 100 toise (fathoms) (195 m) of height. Pascal repeated experiments on the Saint-Jacques tower with a height of about 25 toise (fathoms, 49 m). The difference between the levels of mercury was more than two lines (4.5 mm). At the top of the staircase with about 90 steps, he noticed a difference of 1.1 mm.[249] Thus, even the physically weak Pascal was able to prove his own theory.[250] In fact, the measured results were at hand for centuries, but nobody bothered to pick them up because of the lack of motivations.

At the end of same year, Pascal published his own and his brother-in-law's letter together with the results of the barometer measurements in various French cities: in Paris, in his domestic Auvergne region and in the offshore Dieppe northwest of Paris. The total weight of air in the the atmosphere was estimated at 4 million tons.[251] This figure was, of course, beyond the human imaginations of the time and testified about the triumph of mathematical physics over commons senses.[252]

In April 1652, Blaise demonstrated the operation of his own arithmetic computer at the Parisian saloon of his relative Richelieu and explained his vacuum theory. His research later evolved hydrostatics, which he wrote in 1653. His pamphlet about the discussion of the weight of the air and the balance of liquids was published much later in 1663. With the weight of the air concept, Blaise proved that the weather influences air pressure[253] and thus founded the modern weather science later called meteorology by Aristotelian term.

To recover from the arduous writing about those puzzles, in the following year Blaise took a trip to the surroundings of Paris in late October/early November 1654. Suddenly, the horses went wild, and Pascal "miraculously" got out of the carriage and immediately completed his experiments. He abandoned his mathematical and physical research

[247] 26 inches (doim) and 3.5 lines. The correct result should have been higher.
[248] 500 tois or fathom by 1.949 m, therefore 974.5 m.
[249] Half of a line.
[250] Sparnaay, 1992 15, 17; Tarasov, 1979, 128–129.
[251] 8.5 billion of French pounds.
[252] Pascal, 1648.

because of wild-fired horses; the same kind of more polite animals which almost simultaneously brought glory to Guericke several hundred miles east on 8. 5. 1654. Thus, the year 1654, in truth, we can obviously call a horse year, according to the scientific merits that springs acquired and at the same time wasted.

On 5 December 1661 and again eight days later, six years younger Huygens visited the sick and prematurely aged B. Pascal in Port Royal near Paris. Huygens reported that they discussed the "diluted water" force, today we could say steam in a steam engine. They alsomentioned telescopes imported from Huygens' Dutch homeland. At that time, Pascal was no longer interested in physics, but mainly in theology; but he did not try to get Huygens into theological talks. The Jansenists were present, although the Protestant Huygens was not particularly interested in disputes between Catholics; he was more intimidated by the growing intolerance of his own Protestant faith, which forced him to leave the Parisian beauties all too soon.

The controversy between defenders of the "full" and the adherents of the vacuum was annoying for the next-generation scientists. Even many admirers of empty thought that after exhausting the air, something remains in the container. Inthe theories of Newton and Huygens this "something" was ether. Leibniz, in his last letters of May 1716, rejected the existence of a vacuum[254] and never repented. The philosophical implications of the void seemed much worse than the assumption of the infinitely small one that Leibniz used in the development of the differential calculus.

4.2 Touching Vacuum for the First Time

4.2.1 Introduction

The first Carniolan vacuum researcher, Janez Vajkard Auersperg, did not publish many of his works, since he lived before the modern motto publish or perish; correspondence with the relevant contemporaries was quite enough in those Baroque completely different unmodern times. That's why todays research in the history of physics is increasingly focused on the study of manuscripts or at least the longer handwritten notes in books. This can also be expected, since the main printed books have long been read and illuminated from many aspects, so it is difficult to learn out something innovative from their reading. The manuscripts offer exactly that: the original works.

Due to historical data, most early manuscripts on early vacuum techniques are now stored in European and Asian libraries. Some of them, however, traveled in one way or another, across the large blue pond called the Atlantic Ocean, and they are talking about themselves in our next story.

4.2.2 Two Approaches to Vacuum Dedicated to the Late 17th Century: Manuscripts in Oklahoma University

4.2.2.1 Paolitto's Vacuum Barometer

Four and a half centuries ago, the peer of the Prince Janez Vajkard Auersperg, the Italian Valentino Paolitto, signed himself several times in the cover of the handwriting was, intended for the teaching of applied mathematics, which consisted mainly of astronomy, also of some vacuum and other technical explanations.

In Paolitto's time, the vacuum was a fundamental issue of theology, but at the same time, they studied voids as the lesson of applied mathematics, closely related to the physics of the vacuum. Paolitto's manuscript, in course of those habits, described four fundamental elements of the world, which he dealt with one after the other. Paolitto's writer concluded his discussion with the treatment of water and air; these two have occupied the ideas of liquids and gases in modern terminology. In the next chapter 16, he proved the geoid's circularity and scribbled it with excessively large images of ships and buildings on the bump of the globe of the Earth. He then proceeded to tides, and gently hided Galileo's

[254] Sparnaay, 1992, 19, 39–40; Frankfourt, 1976, 92, 98.

erroneous attempts designed to prove Copernicus's rotation of the earth with tides.[255]

Figure 4-3: Paolitto vacuum barometer from the second half of the 17th century (Paolitto, after 1657, folio 15v, with the permission of the curator of the history of science at the University of Oklahoma, Dr. Kerry Magruder)

Paolitto's writer proved the hydrodynamic paradox by quoting modern research in hydrography and geography.[256] He then proceeded to undertake another treatment of gases, which he has usually referred as "airs"; at that time, they were not yet aware of any gases that were not part of the atmosphere. Immediately at the beginning of the discussion, he cheered the reader with a nice picture of Torricelli's vacuum barometer, which he may have filled with Idrija mercury, although he only mentioned water in all his discussions. Depending on the ratios provided in his picture, the charge with water would not sound reasonable, since the emptied tube in the picture would be extremely large, at least a few meters. Paolitto's writer ensured us that the appearance of the vacuum in the barometer does not in any way cause movement under the influence of force, as the true cause of the vacuum pumping is the dilution force which the writer and his contemporaries conceived for that purpose. The recipient, marked with the letter B,[257] connected an opening facing down into the container with the liquid that he had noted with the letter A. To facilitate the observation of the experiment, the liquid was painted with a color of suitable properties. Closed air in the recipient B dilutes and therefore raises the liquid from the container through a suitable closure marked with the letter C; the liquid compresses the air in the recipient B. In the next second section of the chapter on gases, Paolitto's writer moved to motion under the influence of wind.

Figure 4-4: Paolitto's vacuum barometer from the second half of the 17th century in a mirror image at the start of a second vacuum chapter on air distribution (Paolitto, after 1657, folio 15v, with the permission of the curator of the history of science at the University of Oklahoma, Dr. Kerry Magruder)

The distribution of gases in the atmosphere, composed of three allegedly different used parts, was narrated as a transition to the description of the fire. In this meteorological part of the manuscript, he described the elements of the atmosphere in a series, with the external, third, very hot part used for the passage of comets;[258] for Paolitto's writer the comets were still part of the meteorological phenomena below the Moon, although Tycho Brahe, Kepler and other established astronomers have long been

proving that Aristotle offered gravely erroneous descriptions of comets.

Paolitto's manuscript can be very well dated when reading its ninth chapter on Saturn, where the author explicitly quoted Kircher's opinion about the Saturn's ring,[259] which was soon corrected by the Dutchman Christiaan Huygens in 1655 with a better telescope of his own manufacture. Huygens published his findings in Systema Saturnium in The Hague in 1659. In 1643, during his Bologna observations, Kircher represented Saturn's ring as two sympathetic ellipses on each side of the planet, which he painted in his famous book Ars Magna in 1646 and in a revised reprint in 1671. Besides A. Argoli, Kircher used to be the main source for Paolitto's manuscript, in good and bad. Therefore, the author of Paolitto's manuscript must have been in touch with the Jesuits of Kircher's school, maybe with North Italian Kircher's student Lana from Brescia.

4.2.2.2 Zacco's Vacuum

Paolitto's younger contemporary was the Venetian patrician Augusto Zacco (Augusto Antonio M. Zacchi, * 10 November 1662, Padua; † 18 February 1739, Treviso). Zacco was consecrated on June 1, 1687, and on 15 November 1706 he was appointed Archbishop of Corfu in Greece, which Zacco's native Venice almost lost during their war against the Ottoman Turks. On 22 November 1723, Zacco became Venetian Archbishop of Treviso near Piava river on the Slovene-Friulian ethnic border near the borders of then Habsburg Monarchy, which also acquired Lombardy with Milan of those times. Treviso north of Venice should not be confused with Tarvisio (Tržič) on the tripoint border areas somewhat eastern. As a teenager, Augusto Zacco tried to write a small, perhaps a student book with comments on Aristotle's physics and thoughts about a vacuum in the spirit of Tomas Aquinas. The manuscript was dated on the cover page, on the page before the end and on the ending, respectively in 1680, in August 1680, and finally in November 1681. It spread over the interval of a year and a half, which could be accomplished during Zacco's studies of physics! A little before Zacco's Ph.D., the University of Padua awarded the PhD to the first woman, the Venetian wealthy beauty Elena Lucrezia Cornaro Piscopia (Corner, * 1646, Venice; † 1684, Padua), who then became an university teacher of applied mathematics including physics of then highly popular vacuum.

In the second half of the manuscript, Zacco included his observations of the fourth Aristotle Book of Physics, where he discussed the eighteenth question about the vacuum in a total of eight pages[262] after the discussions of the locations. Regardless of Torricelli's and Guericke's experiments with the help of Carniolan Prince of Ljubljana Janez Vajkard Auersperg, Zacco rejected the existence of a vacuum;[263] he did not even help himself with the experiments as revealed by Boyle, Pascal or Huygens. Thus, he entered the circle of Descartes or Leibniz, who also rejected the vacuum, although in

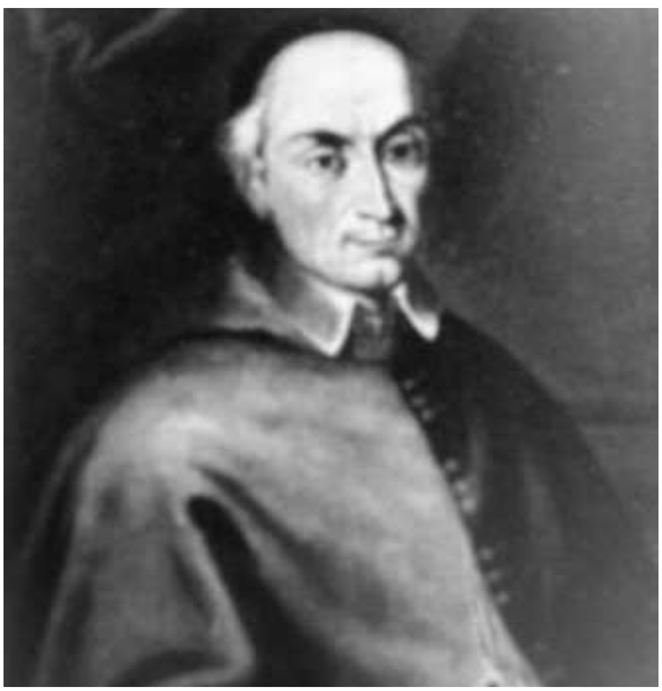

Figure 4-8: Zacco's portrait in oil stored in the Milan house of heirs of his family Adler-Zacco after Lorenzo Zacco from Padua took it over in 1933. Zacco is in bishop's suit; in the right hand he holds a book, probably about the vacuum of his days.[264]

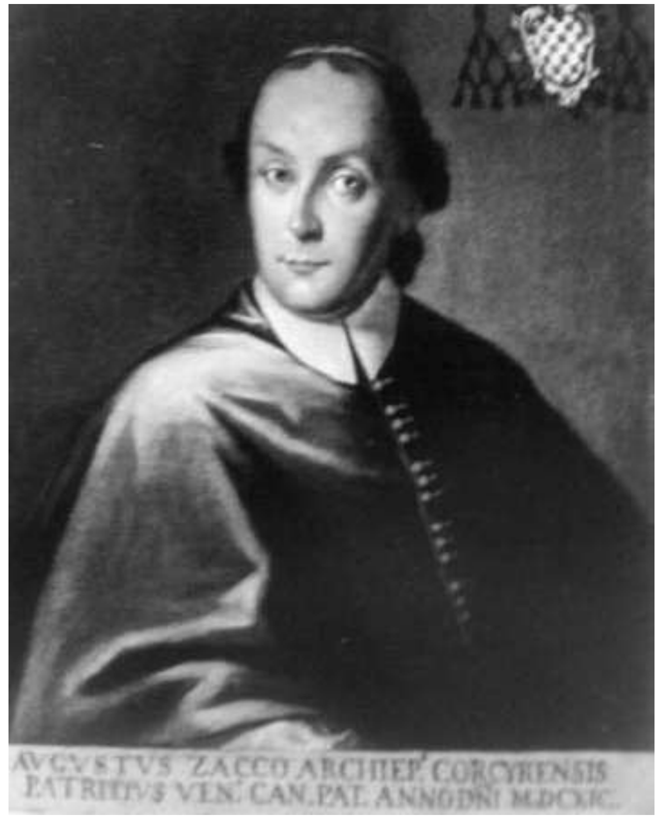

Figure 4-9: Nazzaro Nazzari's (Nazario Nazari, * 1723/4, Venice; † after 1793) Venetian post-mortem portrait of Zacco, oil in canvas, 78 cm × 60 cm, hanging in the Sagrestia dei Canonica cathedral in Padua. Zacco was the canon of Padua named in 1689, and the Archbishop of Corfu, where he became famous for his defense against the Ottoman Turkish invaders.[265]

Venice at the nearby University of Padua, vacuum already for many years acted as a sure fact under the influence of Galileo's heirs of the Florentine Academy. Like many of his cautious contemporaries, Zacco's vacuum more influenced theology than physics, although he seriously considered the possibility of moving in an empty space at the limited time;[266] Aristotle, Descartes, or Leibniz assumed that in the vacuum without resistance, the body would fly long distances at the very moment that, according to the known physical laws, was rather strange. Among the most important Venetian advocates of vacuum was the astronomer Geminiano Montanari (* 1633, Modena; † 1687, Padua), who was invited from Bologna to the Paduan University chair of astronomy and

Grimani (* 1677, Venice, 1752), who was enthroned in 1741. Grimani was a Venetian ambassador to France and England until 1719; there he used his knowledge of vacuum technologies, acquired at Montanari's class, for a particularly genuine friendly relationship with Newton himself. Montanari began to experiment with vacuum in Bologna at the end of 1665, after he improved Torricellian barometer so that he could measure differences in the specific weights of the used liquids, including the sea water. He also studied lead sinking into water according to Archimedes' law. To get the most accurate results he used a thermometer and tried to consider the temperature differences between the individual measurements.[270] He was brave enough to accept the principles of Archimedes, Galileo, and Roberval,[271] although many of Galilean works were forbidden to him with the Papal index. From 1678 to 1687, Montanari traveled between Padua and Venice in a

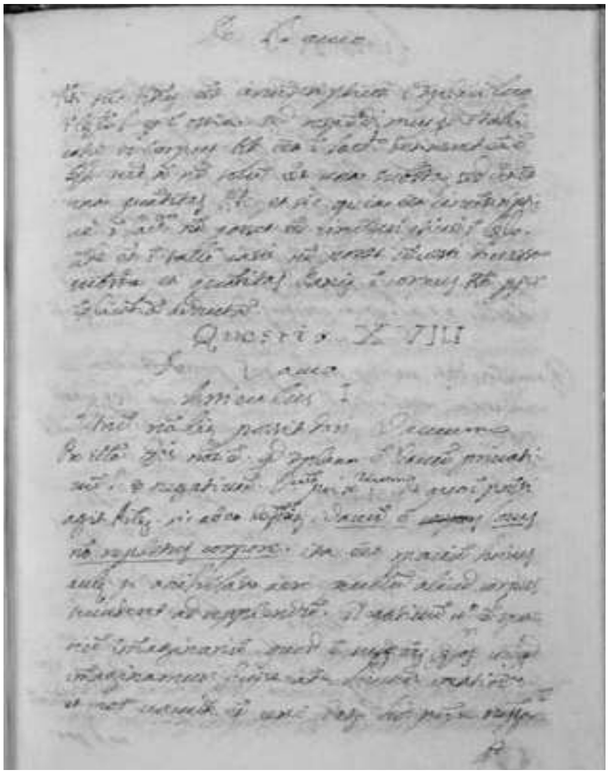

Figure 4-17: The beginning of Zacco's discussion of vacuum (Zacco, 1680/1681, 4, book on page 10r, with the permission of the curator of the History of Science Collection at the University Oklahoma, Dr. Kerry Magruder)

Zacco did not discuss experiments in a vacuum like the simple Torricellian barometer in Paolitto's Spherae. Because of this, Zacco could hardly be considered a student of the Paduan Professor Rinaldi, a distinguished member of the Academy in Florence, where Torricelli's barometer was largely the main attraction. Naturally, Zacco wrote about a philosophical vacuum, not of the so-called Boyle Emptiness (vacua Boiliana), which was considered primarily as a highly diluted air and not as a complete vacuum. The problems of vacuum were certainly inherited from the ancient and medieval problems of physics and metaphysics. Torricelli, Guericke, his assistant Janez Vajkard Auersperg, Boyle or Pascal enabled a great progress, but the problems of the empty have not been resolved forever, as we cannot yet achieve a total vacuum on Earth, nor in the universe where we still find somewhat filled although rarefied spaces. Zacco was certainly a young man with good eyesight during his writing of his booklet with such exceptionally small letters at a time when Ottoman and other wars damaged his Venetian homeland. In any case, with his scholastic notion of empty, Zacco has somehow drifted away from the modern hints of his time.

4.2.2.3 Conclusions

Paolitto and Zacco's manuscripts were provided by Italian scholars of the late 17th century. Both are the echo of teaching at the then universities in Italy, especially in Padua, where many sons of fathers from today's Slovene territory also studied. Both manuscripts, though preserved in America, reflect in their own way the events among the educators in the lands that later became Slovenian republic.

4.2.3 *Galileo's Relative in Carniola Propagating Early Vacuum Technology*

The influence of Galileo Galilei on Carniolans started during the studies of Carniolan youths in Padua, where Counts Auersperg and the noble Valvasor also attended the university. Of course, due to their politically oriented life goals, the nobles did not enroll in the medical faculty where Galilei taught mathematical science. A different level is mirrored in the purchase of the Galilean analogue computer manufactured in his house, in a silver dear version for the rulers including Habsburgs and in cheaper metallic forms; among other things, it was purchased by Counts Auersperg for their palace in Ljubljana, later called Prince's palace, by Valvasor and by Janez Adam Petenegg as the Ljubljana host of Roberto Galilei. The third level of Galileo's influences was the acquisition of his books, including those forbidden, for the Carniolan libraries of Counts and princes of Auersperg, for their Siena classmate, the Radovljica manor owner Count Janez Ambrož Thurn-Valsassina (1616/1624-5, 1654), Janez Vajkad Valvasor, baroness Maria Theresa Wintershofen married Oršić (* about 1665; † 1700), for Franciscans in Kostanjevica and for other Carniolan lovers of good reading.

It is not fair to ignore the other paths of the penetrating of Galileo's ideas among the Carniolans. It's all about an unknown, perhaps even surprising influence of Galileo's relatives. The oldest among Galileo's relatives in Carniola was the chief Venetian trader with the salt Franc Galilei (* Florence; before

17 June 1647); he established himself as an Istrian entrepreneur in the areas of Rijeka, Bakar, Bakarac, Koper, Milje and Trieste in a harsh situation, which soon led to the Zrinski-Frankopan's conspiracy, also due to the actual duty-free zone in Zrinski's Bakar harbor, as a competitor of the Rijeka (Fiume) port with its imperial customs of St. Vid. In those times Bakar was the biggest port in those areas with subterranean sprigs of water everywhere gathered in an artificial lake called Jaz also used for washing the clothes in nearby waters of Perilo. Up the hill there were the Roman and Turkish houses probably used for the trade attachés' deals of Venetian and Ottomans, although the local legends prefer their different stories. Franc Galilei exploited the huge differences in salt prices between the Venetian and Habsburg territories. In addition to the Carniolan archival data on Franc Galileo's trade, Galileo Galilei of Florence connected with the Venetian trader Florentine nobleman Francesco (Franc) Galilei on 4 November 1632. Their deals coincided with the publication of the Galileo's Dialogue dei Massimi Sistemi (1632) before Galileo's call for a fatal trial in Rome culminated in Galileo's conviction on 22 June 1633. The trader Franc Galilei decisively contributed to the regulation of Galileo's Galilei's pension provided by the Cathedral of Brescia on the then Venetian territory.

The Lyonian banker and trader Roberto Galilei (* 1595, Florence) transmitted the messages of the imprisoned Galileo Galilei from Arcetri from Florence to Lyon and to Élie Diodatius (Elia, Elias, * 1576; † 1661). In one of the more shocking letters Galileo Galilei described his grief over the death of his daughterVirginia Mary Celeste Galilei (16 August 1600, Padua, 16 February 1634, Florence) and allegedly blamed the Jesuit for the process against him. Élie Diodati was a Swiss lawyer from one of the leading catholic families in Geneva, to where they moved from Lucca. With the help of Roberto Galileo Élie Diodati organized Elzevir's print of the last Galilean book Discoursi e dimostrazioni matematiche, intròno à due nuove scienze in Leiden in 1638. In the final paragraph of his letter to Elie Diodati, Galileo Galilei presented Roberto Galileo as his relative, to whom Elias Diodati can entrust the contents of the letter; he also mentioned the correspondence with Gassendi and Peiresc, who asked Galileo for telescopic glasses - lenses. On 25 May 1635, Roberto Galilei passed an interesting letter from Galileo Galilei to Lyon for Nicolas Claude Fabry de Peiresc (1580-1637) and Gassendi. It contained thoughts on the magnetic water-clock of Jesuit Franciscus Linus (Hall, * 1595; † 1675) including Roberto's reading and agreement with the ideas of his relative Galileo Galilei.

The connection between Roberto Galileo (* 1595, Florence) and his cousin Roberto Galilei (* 16. 12. 1615, Florence; † 1681, Ljubljana) is significant. Roberto Galilei (* 16. 12. 1615) used to be the captain for the Istrian fourth part of Carniola, the banker and the salt trader. Ljubljana's Roberto was only nine months younger than the first Carniolan vacuum researcher, Janez Vajkard Auersperg; they often met and worked in mutual businesses. The Florentine origin of Roberto Galileo (* 1615; † 1681) and his kinship with Galileo Galilei enabled his influencing of the Ljubljana society with the help of his wife Sidonia Victoria Baroness Mordax (* 1624; † 1665, Ljubljana). Roberto's position in Carniola was extremely high in relation to the godparents of Roberto's children which included the provincial chief, brother of the first prince Janez Vajkard of Auersperg (* 1615; † 1677). On the other hand, Roberto's wife was, among other things, the godmother of the daughter of Karl baron Valvasor († 1697), the older half-brother of Janez Vajkard Valvasor. Roberto's work in Ljubljana has made a decisive contribution to the popularity of Galileo Galilei's works in Carniola. The Provincial Governor and his brother, the Prince Auersperg, kept the main texts of Galileo Galilei including those which were forbidden in their library in Ljubljana. A few years before Roberto's death, the best friend and librarian of the deceased Carniolan Governor general Volf Engelbert Auersperg, the son of the Mayor of Ljubljana Janez Ludvik Schönleben (* 1618, Ljubljana; † 1681) invited from Salzburg the printer and bookkeeper Janez Krstnik Mayr (* 1634; † 1708). In the autumn of 1678 Mayr did not dare to offer openly to Ljubljana natives the forbidden Galileo's works in Mayr's printed catalog, but he offered equally "dangerous" publications of the Protestant Kepler.

Roberto Galilei of Ljubljana (* 1615) had a brother, a distinguished Maltese knight, at a time when the Bishop of Ljubljana became a slightly younger

Maltese knight Josef Rabata. Roberto Galilei (* 1595, Florence) also had a brother among the Maltese knights. We assume that the concentration of the Maltese knights in Ljubljana helped the defences against Ottomans, with Rabatta and Roberto Galilei actively involved. Galileo's multiple connections with the Maltese knights reshaped his much more troublesome connections with the Jesuits.

Roberto Galilei (* 1615) of Ljubljana descended from a Banking Florentine-Lyon family. He was adopted to the Lyon branch of their family of his older cousin and importer Roberto Galilei (* 1595, Florence). After the Galileo Galilei's process, Roberto (* 1615) was too young in his early twenties to get a sensible engagement in the events and to help his cousin Roberto to conceal the letters of Galileo Galilei in secret. In addition, Roberto Jr. was sent to Carniola shortly after the end of his teens to expand the banking operations of his father Ottavio. Of course, the fateful events following the Galilean process were closely monitored and decisively defined the relationship of the Ljubljana high society to modern science during Roberto's (* 1615) half of a century spent in Carniola.

Roberto Jr. (*1615) was trading with other Ljubljana businesspeople, mainly with traders such as Zacharia Waldtreich and Zergoll(ern). Roberto took over the first devices from Galileo's workshops for Carniolans, which was proven above all for Galileo's analogue computer noted in the legacy of Roberto's Ljubljana host Hans Adam Pettenekh on January 23, 1705[276] and in the legacy of Janez Vajkard Valvasor in 1694. Here we would be even more interested in Roberto Galileo's telescope or even the Florentine mercury thermometer, but up to now, unfortunately, the archival data are still silent about those facts. We also do not know for sure whether Roberto or his peer and neighbor, the Prince Janez Vajkard Auersperg, operated a vacuum pump or barometer in Ljubljana.

When he learned of Périer andPascal experiments, Guericke repeated them with the first useful barometer filled with the water in 1660. The pipe with water reached the third floor of his house, and a figure in the wood floated in the water as a pointer. The pump was installed on two floors of his house. The neighbors were originally muzzled at the expense of their mayor, who filled the house with strange devices. On a beautiful day, Guericke noticed that the air pressure had dropped dramatically two hours before a terrible storm, and urgently warned his neighbor citizens.[277] An exact weather forecast, which is only rarely achieved by modern meteorologists, of course, enabled Guericke's great political reputation. The housekeepers were deeply grateful to him, so next time he was re-elected by a landslide. Today, this could perhaps be said to be a scientifically supported political campaign, which, unfortunately, is not the best established in Slovenian politics.

Guericke also tried to repeat Pascal's barometric experiments on nearby hill, but his servant was far too clumsy and broke the heavy (and costly) barometer which he was supposed to carry.

Boyle and Hooke measured down to 7.9 mbar (6 torr).[278] Guericke estimated the pressure at Torricelli's experiment at 13 mbar at the same time. In 1660, Boyle listed the experiments carried out in 1658 and 1659 with the first Hooke's pump, using a mercury gauge in the bell. Thus, several centuries of fruitful competition for the best available pumps and pressure gauges have started. The goal was the lowest pressures that they were still able to exhaust or measure (Figure 4-18).

In 1662, Boyle published his measurements of diluted air pressure in the second edition of his "New experiments" and wrote his findings that we now call the Boyle Law. In 1679, Mariotte independently carried out Boyle-like measurements with decreasing air density at higher temperatures. In 1699, the Frenchman Amontons published the same law for all gases. Most of the later studies of gas laws were carried out in Paris: in Charles' lab around 1787, by Gay-Lussac in 1807 and in Regnault's group lab after 1840.

The "New experiments" together with the other two Boyle books were offered by the bookkeeper Mayr under the title "The Tract on Air" in Ljubljana in

[279] Redhead (1999, 142).

1678.[280] Boyle tabulated experiments with the rarefication of air down to the pressures of 42 mbar. He rejected Linus' defense of Aristotle against air pressure. According to Linus, the mercury in the barometer is held 0.76 m high by the invisible membrane "Funiculus" from diluted mercury, which we could even touch by sealing the voided vessel with our finger[281]. Similarly, the theory of small "vacuums" that hold the 10 m column of water upright in the pump has already been advocated by Galileo in his interpretation of Heron's experiment, and therefore in their times it was not so unusual or even funny as it seems to us today.[282]

Kircher's student **Francsiscus Linus (Hall)** was a Jesuit of English descent, a professor of mathematics at an English college in the Belgian city of Liège. After Cromwell's death in 1658, he was able to return to London for a short visit, but he soon had to return as the unwanted Catholic. He was especially well-known for his controversy against Newton theory of colors, which he published shortly before his death in Phil. Trans.

Boyle refused Linus's ideas with a nice trick. By sucking, Boyle lifted the mercury column at the open end of the barometer by 2.2 m higher than on the closed end. Linus did not give up, and he repeated Pascal's experiment, but with the opposite result. He claimed that the height of the mercury column was the same at the top and at the foot of the hill. Of course, there were no particularly high hills around Liège except for Ardennes; in addition, Linus was already approaching his seventies, and he was not strong enough to carry up that heavy mercury anymore. In 1711, Leibniz, Réaumur and others differed in their terms of the decrease in the mercury level in the pipes during the rainy weather. But at the end of the 17th century, barometers for sale were already being manufactured in England, and soon afterwards in Europe. The philosophy of the vacuum was pushed along the side, the technical achievements advanced in the foreground. Whatever might be inside the vacuum, those tools were industrially useful.

5 Pumps & Maintaining the Vacuums with Getters

5.1 Pumps in the Second Half of the 17th Century

5.1.1 *Guericke and the Research of Vacuum in the German Speaking Provinces*

Guericke carried out his first vacuum experiments in 1640. Eight years later, he put together an early version of the "Magdeburg hemispheres".[283] During the reading of Descartes's Principles of Philosophy (1644), he concluded that the controversial existence of a vacuum would be proven by experiments. Thus, Descartes, with his mistakes, encouraged his opponents Guericke, and later even Newton.[284]

For his first pump, Guericke filled a wine barrel or beer barrel with water, sealed it well and then left the water out through a low-mounted copper tube. The barrel crashed before the water had totally run out. Later, the wooden barrel was replaced by bronze one. In 1650, Guericke assembled an air pump, with which four years later in Regensburg he carried out a famous experiment with Magdeburg hemispheres in front of the Emperor Ferdinand III, Carniolan Auersperg and other princes the electors. He did not use moveable contacts in the form of cones and sleeves. The bronze hemispheres with a diameter of 0.68 m[285] was better sealed with a ring made of the skin, which was impregnated by the mixture of wax and turpentine, although sometimes it was sealed with resin. The pull mode was later described as "fast"; as he usually hired two powerful men who emptied the hemispheres in two or three hours, which is not really very fast in today's eyes. Of course, they pumped for good money, which was not lacking in the trustworthy pockets of Mayor Guericke. He used five different large exhausted vessels, the largest was ten times bulkier than the smallest.[288]

[283] Sparnaay, 1992, 4; Madey, 1984, 11.
[284] Hablanian, 1984, 18.
[285] ¾ of a yard.

After a successful experiment in Regensburg, many princes wished to buy a wonderful machine. Guericke sold the device to Schönborn,[286] who offered him the most. The wealthy buyer was the Prince of Wurzburg and Worms and the Archbishop-Elector of Mainz; therefore, it was not hard for him to pay some extra gold coins. He did not buy the pump for himself but gave it to the Jesuits from the University of Würzburg. As early as June 22, 1655 in Mainz, Schott wrote to Kircher about Guericke's device, before taking it over together with the Chair of Mathematics at the University of Würzburg in 1655/56. Schott was a friend and a pupil of Kircher, so he quickly found out what treasure had just fallen into his hands. He began to correspond with Guericke and to publish his achievements. Although Schott was a professor in Würzburg for ten years, not far from Guericke's Magdeburg, we have no testimony to their possible personal meetings. Their different faiths were not the fatal hindrances, as Guericke's son paid a courtesy visit to Schott's teacher Kircher in Rome.[287]

The first two Guericke's pumps were a reversed fire extinguishers with a bronze cylinder, a wooden piston and a copper sphere, which was used in the second version for a exhausted vessel. In 1657 Schott published the first sketches of Guericke's pumps. At first, he intended to describe hydraulic and pneumatic devices from the Kircher's Roman Museum, and later included other experiments.[288] He dedicated his work to Schönborn,[289] who, certainly, opened his purse wide to become a great benefactor of early vacuumists. Therefore, of course, Schott dedicated to him another book in 1664, since his professor's salary was not nearly enough to print such large and well-illustrated works.

Schott did not recognize vacuum as something completely void. His friend and patron Dobrzensky Nigro Ponte[290] from the established Prague medical family held similar opinions. Nigro Ponte preferred to swear on the mercurial vapors above the barometer. Nigro Ponte criticized the

[290] Schott, 1664, 252, 885.

alchemists, so Carniolan Rain published a book in Ljubljana against him focused on the human saliva and dedicated it to Emperor Leopold I. The clever emperor did not send golds only to Carniolan Rain, but he also supported the opposite books of Nigro Ponte and of Nigro Ponte's model Kircher; of course, they also filled their works with magnificent dedications to the emperor. Unfortunately, the similar emperors, princes or at least elector dukes are now almost completely overlooked so we the modern writers witness much poorer stream gold into our empty pockets, if we do not kindly get help from any ministry. In 1662, using the Boyle's early work, Guericke composed the third version of his pump nicknamed "Reiseluftpumpe". It happened be without the disadvantages of the first two designs. He used a leverage system for pumping in the manner of reversed manual fire extinguisher, which was supplemented with a valve on the lid and reduced the volume of the exhausted vessel. Instead of water, he directly pumped out air, which was one of his most important novel contributions to vacuum technology. Three original Guericke's products are kept today at the Technical College of Braunschweig, the Technical Museum in Malmö and at the German Museum in Munich.[291]

On 14 March 1663, Guericke completed seven parts of his book, which was only published a decade later because of his overemployment and occasional diseases. Although the Auersperg prince had already felt into imperial disgrace during this time, Guericke published a detailed description of their mutual research of vacuum. With this, the Early Carniolan science set up a magnificent monument, which modern Slovenian vacuum researchers are proud of. Guericke used their devices as "syringes", "*Antlia Pneumatica*" and in 1662 "Reiseluftpumpe". Boyle baptized his pumps for "pneumatic machines". The names such as the air and vacuum pumps were established later. Schott and Guericke criticized the usefulness of Hooke and Boyle's pumps, and the brave Englishmen made their good returns with heavy interest. Part of the criticism came from poor information; Hooke and Boyle knew only the first version of Guericke's pump from Schott's book. Schott and Guericke considered that the pump of their colleagues beyond the English Channel was badly sealed as they were not informed early enough of Boyle's improvements. Nevertheless, they occasionally borrowed ideas from each other for individual parts of the pumps without considering much of the copyright. Just for his experimental facilities, Guericke used up 20,000 Thalers; at least so narrated his son, who spent the last five years in Hamburg. Guericke's work divided in seven books was not published until 1672. The Amsterdam printer did not pay Guericke's honorarium, but after painful negotiations delivered only a few copies of the book to Guericke.[292]

The first vacuum experiments have not yet yielded promising profits, but they harvested plenty of honor. In 1666, Emperor Leopold I elevated Guericke to the noble ranks, so he was proudly signed with the adjective "von". The Almighty Auersperg prince supported the advancement of his friend Guericke, although he was no longer as proudly honored by his new emperor, as he used to be by Leopold's imperial father and brother in his better time.

.

5.1.2 Auersperg, the First Carniolan Vacuum Enthusiast

5.1.2.1 Auersperg and Guericke

Three and a half centuries passed after the famous Guericke's experiment in the Bavarian Regensburg. On the banks of the Danube, the spark-horses pulled out two semicircular discharged hemispheres on each side: without success, but with a big pomp. Only a decade ago, Torricelli and Viviani put together their barometer; but the Florentine academics did not promote their invention on the big bell in fear of a possible repetition of Galileo's condemnation. So, a lot of water has passed before Carniolan Idrija miners started selling much of their mercury for barometers. Only Guericke, Carniolan Auersperg and other great men first publicly discussed vacuum experiments in Regensburg. The validity of scientific assumptions and experiments was judged by the then educated nobles who were accustomed to solving technical problems while they swinged their swords during the thirty years of war. Regensburg and Carniola were parts of their common Holy Roman empire at that time and a century and a half later. Since Carniolans were

[291] Schneider, 1986, 398–399.

[292] Guericke, 1986, 109; Shapin, Schaffer, 1993, 277–278.

always the right people in the right places, we should not be surprised that they have significantly interfered with the very beginnings of the vacuum technique. The state gatherings were meetings of the Central European cream that could not pass without a joyful Carniolan nobility. The Gottschee (Kočevje) landlord Ivan baron Ungnad was the adviser to Emperor Ferdinand I at the National Assembly in Regensburg in 1546. Later, he became the most prominent supporter of Primož Trubar together the Auersperg family. The provincial Governor Janez Cobenzl from the Predjama castle near Postojna joined 15000 followers of Emperor Rudolf II, the grandson of Ferdinand I, at the National Assembly in Regensburg. Unfortunately, he died there and never saw his homeland again. He was the grandson of the famous Carniolan Robin Hood, Erasmus of Predjama (Lueger, † 1484), and the father of the Jesuit mathematician Janez Rafael Cobenzl. Janez Rafael learned modern science from Grienberger, Clavius' successor at the College of Rome. In 1626 and 1627 he was an adviser to the Austrian provincial and the Rector in Vienna where he significantly influenced the education of one of the heroes of our story, Janez Vajkard Auersperg (* 1615).

In 1653 and 1654, Carniolan nobles attended a gathering in Regensburg. The most important among them was newly inaugurated Prince Janez Vajkard Auersperg (Figure 5-1). He was the great-grandson of the famous military leader, Baron Herbert Auersperg, who bravely fell under the Turkish sword, and the grandson of his eldest son, Kristof. He was born as the fourth of five sons of hereditary Marshal Ditrih Auersperg. Ditrih inherited the Žužemberk castle after a fire that destroyed the building during the Easter celebration in 1591. In 1631 he bought the nearby manor Vrhkrka, which his son Janez Vajkard inherited after his death. In 1625, Dietrich (Ditrih) among the last Carniolans returned to the bosom of the Catholic Church. At that time, he bought two houses at the crossroads of Gosposka and Turjaška ulica (street) in Ljubljana, which he rebuilt in 1631 and 1632. On 16 September 1630, he became the imperial count and his sons inherited that privilege. Thus, Carniolan hero Janez Vajkard spent his youth and the first school years on the same street opposite the provincial house, where the other two Carniolan princes and the Viennese ministers Eggenberg and Portia also lived. Portia was married to the first cousin of Janez Vajkard, so that alongside the neighborhood ties they added their marriage connections. Between 1635 and 1650, Portia was a provincial judge in Carniola, then became "ajo", the highest court master and educator of the young Emperor Leopold. Together with his relative, the prince of Auersperg, they raised both Emperor's sons and brought them up with Carniolan wisdom. Naturally, after his enthronement, Leopold I gave much more confidence to his former educator Porta.

Figure 5-1: Auersperg Prince Janez Vajkard (* 1615; † 1677) in his younger years.

Ditrih's oldest son, the Count Volk (Wolf) Engelbert Auersperg, bought the Kočevje and Poljane domains on July 9, 1641, and after a few months he continued with his father's constructions in Ljubljana.[293] In 1649, he became a regional leader Governor General, and next year he built a castle on the edge of the then town of Kočevje. On 20. 4. 1660, he began to build near his father's northern half of the "princess castle", on the southern part of today's Plečnik's NUK in Ljubljana. There he staged the opera according to the Venetian example. He completed the construction in two years. Near the Duke's Castle, the first cousin of Volk Engelbert, the Count Janez Andrej Auersperg from Turjak, brought together three buildings for his new Auersperg Count's

[293] Mal, 1925, SBL, 1: 19.

Palace at Gosposka and Križevniška Street between 1654 and 1659. Today, there is the Municipal Museum on Gosposka Street no. 15. Thus, the Auerspergs of Kočevje and their relatives of Auerspergs of Turjak, lived in magnificent buildings in the middle of the New Square, which became the provincial administrative noble part of Ljubljana. The count Volk Engelbert decorated his mansion with the richest noble library at the then Carniola, which his ancestors began to collect on the Auersperg castle in the 14th century. Meanwhile, his younger brother, Janez Vajkard, led the politics of Emperor Ferdinand III who was educated by the Jesuits as a capable linguist and composer of church music. When Janez Vajkard completed his studies at the aristocratic colleges, the Emperor entrusted him with the education of his oldest son the crown prince Ferdinand IV. In 1637, Janez Vajkard became a courtier. Two years later, his elder brother Herbert Auersperg joined the Viennese Spanish court of the Empress Maria Anne of Spain. Herbert Auersperg married baroness Moscon from Krško near Šrajbarski Turn in 1649.

On 7. 9. 1653, the Emperor promoted Janez Vajkard to the great rank of state prince. The ceremony was staged at the National Assembly in Regensburg, three months after the crowning of the crown prince Ferdinand IV. Janez Vajkard got to the fiefdom county Wels in Upper Austria. The following year, the emperor gave to Janez Vajkard the Silesian principalities of Münsterberg (Ziębice) and Frankenstein (Ząbkowice Śląskie) which belongs to the Polish Sudeten today. Carniolan Janez Vajkard became a secret councilor, a golden fleece knight, a conference and state minister. His rival, Lobkowitz, at the same time received the title of a secret councilor and, together with Portia, spearheaded the imperial foreign policy. The popular successes of Janez Vajkard were crowned with his personal ones. On November 20, 1654, he celebrated a cute wedding with a countess from the Losensteiner castle at Steyr in Upper Austria. Her father, a courtier count Jurij Ahac, died during the assembly in Regensburg, two months after his future son-in-law got the title of prince. Soon the funny old death picked up Jurij Ahac's wife, the noble Mansfeld. Of course, their very poor orphaned daughter was quickly comforted by Carniolan great prince, while the couple gave birth to their eight children. The Carniolans were worth their money.

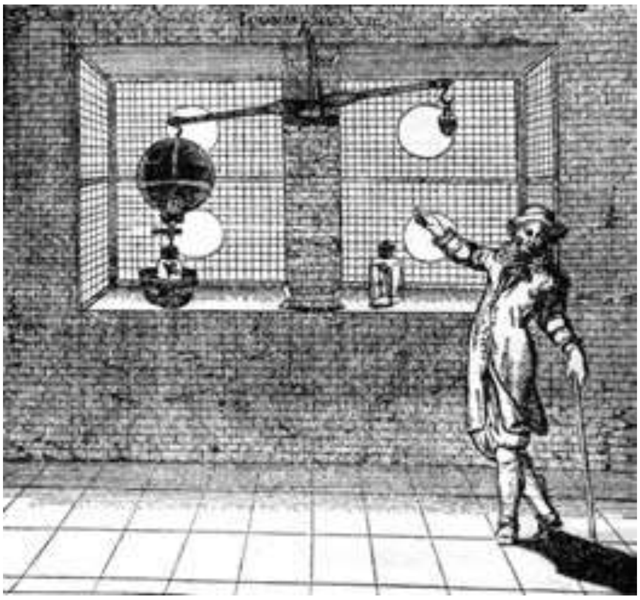

Figure 5-2: An experiment which Guericke pointed to the Auersperg prince in Regensburg in 1654.[294]

The origin of Guericke's family lacked Auersperg's noblesse. He was born in the family of officials and patricians who lived in Magdeburg since 1315. Among his ancestors, there were as many as thirteen mayors. He studied philosophy and law at universities in Leipzig, Helmstedt and Jena. He completed his education at Stevin's Engineering School in Leyden, then expanded his horizons with journeys across England and France where he met Boyle and Pascal's networks. After returning to his native Magdeburg, during the Thirty years of war he began to work in politics in 1626, and after twenty years he became one of the five mayors in the city. In the meantime, he spent a lot of dreadful hours, especially after Marshal Tilly took over the command of the Imperial Army in 1630. On May 20th, 1632, Guericke successfully escaped from the burning Magdeburg only because his father-in-law was in contact with Tilly's officers; Tilly's have given their fatal swords as final presents to the two thirds of the thirty thousand Guericke's fellow citizens. Bosnian Srebrenica is by no means a novel invention.

The Protestant Guericke served as an engineer in Swedish and then in the Saxon army during the war.[295] Despite his understandable resentment towards Tilly, he co-operated with his Emperor Ferdinand III, who personally assumed the command of the army four years after Tilly.

[294] Guericke, 1986, 76.
[295] Hellyer, 1998, 279, 280.

Guericke was representing the benefits of his city at the Osnabrück conference, where between 1645 and 1648 those funny folks finally agreed on peace after a thirty-year war. There he met Janez Vajkard Auersperg, who attended the conference in the Embassy of the Emperor. They saw each other again during Guericke's visit to the Viennese court.[299] The inventive Guericke already wanted to report on his vacuum experiments at that time.

.

Guericke attended the National Assembly in Regensburg as a full-fledged politician. He presented to the Emperor and prince his experiments with air pressure and told about new, barely discovered phenomena. He ensured the doubtful nobleman that the atmosphere above us presses on all hollow bodies that are not completely fully filled with wood, stones and similar substances. The air fills all the voids; but if it does not, it presses the empty containers to transform them.

The clever mayor was first weighing his air, which would still be considered today for a wasting of time. He equilibrated his balance with a vacuum container on one hand and with the weights on the other side. After he emptied his container, he found that some weights needed to be removed on the opposite side to retain the balance (Figure 5-2).

In the second experiment, the quadruped container was exhausted and sealed with a valve. The container did not withstand the external pressure and it collapsed in a thousand and one piece with a sharp crack. The circular vessel did not burst in a similar experiment, because it was not so easily deformed by the external pressure. Guericke told Emperor Ferdinand III, King Ferdinand IV, Auersperg and other princes about his experiments in an empty space, and by the way he mentioned that we run out of air when we blow into vacuum container. He knew that many dangerous things could happen to us, since the external pressure does not only squeeze out all the air from the human or animal body into a exhausted vessel, but even damages the body with the gut included. Because of pressure, we can even die. The Auersperg prince did not believe much in the empty words: he demanded an experimental proof. He was not prepared to abandon Aristotle's science from his student benches, where the vacuum seemingly opposed any common sense. Even the recently deceased Descartes did not approve total emptiness. The Carniolan noble Auersperg wanted to examine the circumstances in an exhausted vessel. The Auersperg prince was then in his thirty-nine year of age and was almost more powerful than the very old emperor. The doubts of the powerful prince had questioned all other Guericke's experiments. It was a question of personal prestige: will Guericke convince the prince of the validity of his considerations? The engineer Guericke was not particularly at home in Aristotle's logic, and he did not want to go into discussions about the nature of the vacuum, which was often blown by his rival Boyle beyond the English Channel. In an empty space, he saw a useful utility for the propulsion of machines; only two years after Guericke's death, Denis Papin fulfilled those ideas after he took over the chair of mathematics at the University of Marburg, 250 km southwest of Guericke's Magdeburg.

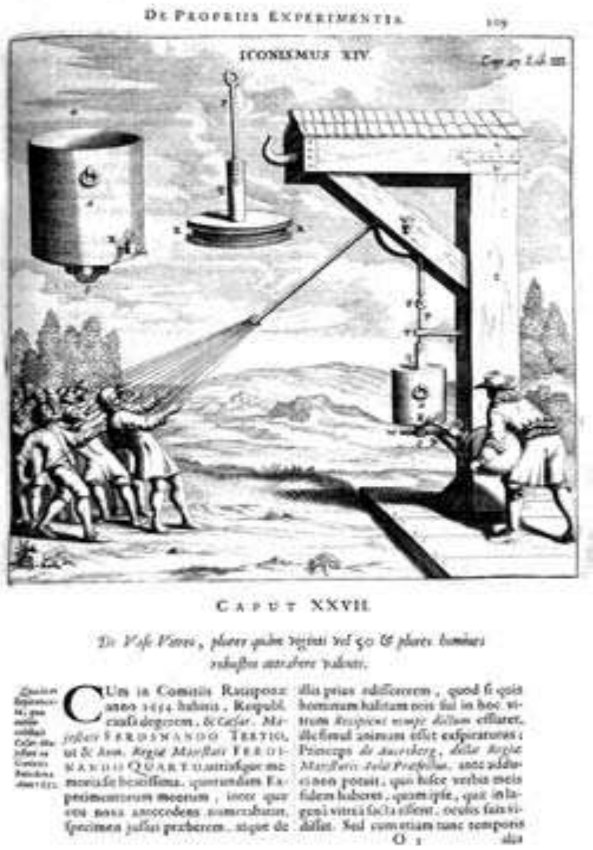

Figure 5-3: This is how Guericke persuaded the Auersperg prince that the vacuum really existed.[296]

Guericke avoided a scholastic dispute with Auersperg and left the decision to his experiments.[297] To remove doubts from his

[296] Guericke, 1986, 78.
[297] Hellyer, 1998, 280–282.

demonstrations, he hired twenty, thirty and finally hundred people who could not lift the lid off the empty exhausted vessel (Figure 5-3).[298] He calculated that the air pressed on the lid with a force of 13 kN, which thirty or even fifty men could not overcome. Apparently, he did not deal with the especially strong guys.

Guericke then replaced his hired people with weights and thus weighed the air pressure.[299] To the Carniolan prince and other surprised grand magnates Guericke showed how the vacuum "pulls" water up the tube, extinguishes the candle and suffocates the ticking of the clock. To the lovers of grapes and its processed forms, which at that time were not lacking and are not lacking even today, he served a very welcoming news: "Finally, it should be mentioned at this point: when we place the grapes in such a glass container, we empty it and then store it in a cold place for half a year, the grapes' appearance will not change, but they will lose all the juice." He explained the success of the vacuum preservation: "From here, it follows that the juice escapes into the empty space is evaporated, while otherwise it would return backwards and remain in the interior due to the pressure of the surrounding air."[300]

All that was not enough for the vile Auersperg. As a genuine knight of his time, he wanted to resolve the plot with an empty space, as it is suitable for the grandson of the commanders of the Habsburgian armies. The cavaliers of the knights' tournaments mostly trusted their sparkling sparrows; therefore, they ordered to their horses resolve the vacuum puzzle. The assembly in Regensburg was boring, so every party was welcome. The Magdeburg hemispheres experiments were the summit of several months of debates and experiments in Regensburg. The expectation was gigantic, the enthusiasts even bet on that or the opposite side. The emperor himself, Auersperg and other elector princes extended their stay in the city to see what Guericke's horses would do.[301] Preparations for the first large, luxurious event in history have raised a lot of dust but the clever Guericke dwindled all opposition after he had precisely recalculated all the conditions regarding the surface and diameter of the spheres and the number of horses needed (Figure 5-4).[307] Let's ensure that Carniolan Auersperg would not be able to find some problems again! The calculations convinced Guericke that, God forbid, the horses will in no way be able to disassemble the hemispheres when the air is exhausted from the space between them. Certainly, the pressure was almost twice higher than the power of horses. Auersperg, of course, was equally well prepared by preventing Guericke'seventual cheating by any helpless old horses.

Figure 5-4: An experiment with Magdeburg's hemispheres, which Auersperg's saw in 1654 in Regensburg.[302]

Then horses dragged, dragged ... Finally, the wide-eyed hats of many curious people, princes and with a slight delay, even the Auersperg's hat itself flew into the air. The Magdeburg mayor won. The last doubter had to admit that they were witnessing a new chapter in physics. Of course, many spears have been broken during next half of a century over the explanations of vacuum phenomena with empty space, air pressure, invisible filaments or vapors. The vacuum entered the Central European High Society in a particularly magnificent way, under the critical eye of Carniolan Auersperg prince.

5.1.2.2 Auersperg Prince in a Political Vacuum

The news of the Magdeburg hemispheres quickly swept Europe. On 22 July 1656, Guericke reported to Schott about the experiment with copper hemispheres in Regensburg (Figure 5-4).[303] The Prince addressed the Emperor to invite Guericke to

[298] Guericke, 1986, 77.

[303] Schott, 1657, 460; Schott, 1658, 604; Schott, 1664, 18, 39.

Vienna. A famous experiment with horses that in vain tried to separate two hemispheres held together only by air pressure was repeated by Guericke at the Emperor's Viennese Palace in 1657, shortly after the death of Emperor Ferdinand III. The strong Carniolan horses Lipizzaners were encouraged by the most beautiful ladies of the Empire, but they did not split the hemispheres. The Carniolan prince was already for a long time the top guy in the imperial city. His protégé the king Ferdinand IV soon got his fatal smallpox pest and died. The throne was taken over by his younger brother Leopold I, whom the Jesuits had so far educated for church services. He was still young, and therefore, he was led by Auersperg, his adviser and the first minister. The Emperor and Prince, under Guericke's influence, became interested in vacuum technique, so in 1658 they visited Schönborn, Schott and the Jesuit College in Würzburg.[304]

After the printout of *Oedipus* (1658) Janez accompanied the new Emperor Leopold I. The emperor Leopold I and Janez visited Schönborn and Schott's Jesuitical college in Würzburg in 1658.[305] Schönborn grew up in a mixed family full of religious tolerance and was hoping to unite both churches. He codesigned a League of the Rhine River for the French king against the emperor.

During the year following the death of Ferdinand III the Parisian first minister the Cardinal Mazarin obstructed the election of Leopold I for the Emperor until Lobkowitz, collaborator and rival of Carniolan Prince Janez Vajkard Auersperg, convinced Schönborn to give his vote for Habsburgian at the state council. Auersperg's rival Wenzel Lobkowitz addressed and talked over Schönborn to give his own votes to Leopold I, and thus transferred the scales to gain the Imperial title in Leopold's favor. Schönborn's vote was vital as only eight eligible voters participated in the elections of new emperor. The electoral prince and Archbishop of Mainz (1642-1673), Würzburg and Worms Prince-Bishop Johann Philip Schönborn have agreed to give his (both) votes to the Leopold's election. These (two) votes have decisively stopped conspiracies for the election of the Bavarian candidate. That success, despite the lord protector Oliver Cromwell's (1599–1658) and Mazarin's conspiration favouring the Bavarian prince-elector Ferdinand Maria (1636-1679), however, rearranged scales of eight appointed electors. Leopold got imperial title at the coronation in Frankfurt am Main on August 1, 1658. The archbishop of Mainz Johann Philipp von Schönborn performed the coronation as Frankfurt was in his province of Mainz. The probable freemason Oldenburg also attended that fest of coronation while he served as a home teacher and travel companion of R. Boyle's nephew Richard Jones; Oldenburg has certainly met Prince Janez Auersperg there even if the number of people attending was huge. Katherine Jones viscountess Ranelagh's (1615-1691) son Richard Jones (1641-1712) 1st Earl of Ranelagh FRS, known as the Viscount Ranelagh between 1669 and 1677, was an Irish peer, as well as politician in the Parliaments of England and Ireland. Robert Boyle spent his last almost quarter of century in his sister Katherine Jones' household in Pall Mall in central London while Oldenburg also lived and died in the same street with his own wife. In that way, Robert Boyle could indirectly exchange his experience of pumping of the air with Guericke's former assistant Prince Janez Auersperg. Later, Oldenburg and his protégé somewhat bisexual Richard Jones rode to Mainz and met a promising young erudite Becher.[306] A decade later Oldenburg has drawn up detailed instructions for the visit of Edward Brown (* 1644; † 1708) in Carniolan and nearby lands in 1669: Brown's travelogue was also published in Oldenburg's *Philosophical transactions* of RS[307] but Valvasor was not particularly impressed and he criticized Brown's narrations as the allegedly better informed native.

On 6 September 1660, the prince traveled with his wife across the Alpine Ljubelj and arrived in his brother's Ljubljana's mansion. There they prepared a reception for the Emperor, who came to White Ljubljana for a hereditary homage during the following day. Between 18 and 24 September 1660, the ceremony was repeated in Gorizia, where the Jesuit Baučer spoke as the first historian of Slovenian origin. In 1663, the Auersperg prince bought the County of Thengen in then Upper Austria (later Tengen in Baden) and made it the princely manor with his purchase. He preferred to relax in the forests of Carniola. That is why, the Prince bought the Carniolan manor Pazin in Istria

[304] Hellyer, 1998, 100.
[305] M. Hellyer, Jesuit Physics, In: *The Jesuits cultures, Sciences, and the Arts 1540-1773*. 1999.
[306] M. Boas Hall, *Henry Oldenburg*, Oxford 2002, 34, 36.
[307] Šumrada, 1989, 56.

on 18 June 1665. In the following year, Paz and Krašan in neighborhood joined his Pazin. The prince and his brother Volk Engelbert each bought a half of Belaj near Paz, 15 km east of Pazin. However, the days of the harmony between the prince and the increasingly independent new emperor passed. Carniolan Auersperg wanted a cardinal hat, which, unfortunately, very rarely adorned the Carniolan head. He did not even inform the emperor about his negotiations with the Papal headquarters. At the same time, he tried to change the foreign policy of the Habsburgs who opposed the French during the thirty years war and after that. This was not possible during the time of Italian Mazarin, who won the cardinal hat in 1641, and the chair of the first Parisian minister two years later. Mazarin took care of French domination in Europe and despite the death of Ferdinand III hampered the election of Leopold I to the post emperor until Lobkowitz persuaded Schönborn to vote for Habsburg. A year after the death of Ferdinand III the Parisian first minister the Cardinal Mazarin obstructed the election of Leopold I for the Emperor; until Lobkowitz, collaborator and rival of Carniolan Prince Janez Vajkard Auersperg, convinced Schönborn to give his vote for Habsburg at the state council and thus influenced game for the Imperial title in Leopold's favor.

The angry Nikola Zrinski (d. 1664) with his brother Peter and his brother-in-law Franjo Frankopan announced to the National Assembly in Regensburg (1663-1664) his intension to seek a new ruler if Leopold will not protect the Croatian interests under the current unfavourable Peace of Vasvár (Železnograd). However, Auersperg's and Carniolan nobility remained deaf to that mutiny conspiracy invitations for the rebellion except for a Styrian Ivan Erasmus Tattenbach (1665) and Gorizia chief Karl Thurn (1668).[308]

After Mazarin's death and a benevolent Habsburg peace agreement with the Ottoman Turks in Vásvar on August 10, 1664, Auersperg felt that the time had come for a reversal. He had a lot of promises from Mazarin's successor the lover of books Colbert, who in 1665 became the chief controller of French finances and in 1669 the naval minister. The French ambassador to Vienna between 1664 and 1673, the General Lieutenant Colonel Grémonville, completely mastered the Viennese diplomacy of Lobkowitz and Auersperg. In addition, the Emperor Leopold I was in close kinship and friendship with the French king. Despite the unexpected French occupation of Belgium on 26 May 1667, a few months later, the emperor concluded a secret agreement for the possible division of the Spanish heritage with the Sun king Ludvik XIV on 19 January 1668.

After the death of Auersperg's relative Portia (Porcia), Lobkowitz assumed the position of the first counselor at the court. The prince Auersperg's alleged secret negotiations with French diplomats and the Pope came to the Emperor's ear. The emperor could hardly wait to get rid of his father's former protege with his annoying patronizing. At the request of the Spanish court, the emperor pushed Auersperg in his early retirement in 1669 and sentenced him to death for the sake of his alleged betrayal. The French were of course surprised, as their negotiations with the Auersperg did not go beyond the boundaries of conventional diplomacy. The plot grew up mainly as a master minded hoax of Auersperg's opponents. In any case, the frightened Auersperg hid himself in Venice for two years and waited for more pleasant winds from Vienna.[309] Of course, his hosting at the hostile dodge's networks did not bring him the love of the Viennese rulers; nevertheless, he was forgiven by the benevolent emperor who "only" banned him from the court.

The new first minister and director of the cabinet became Lobkowitz. An obtrusive Auersperg was dismissed after his premature deals. Lobkowitz soon rolled the policy into a short-lived Catholic alliance with Paris and Madrid. He retained the position of the deposed Auersperg prince until 1674 and died only a few months before him. After Auersperg's departure, Leopold I double-crossed the French candidate for the succession of the Polish King Jan Kazimierz. On 19 September 1669, the Polish "Szlachta" convinced with a good strong drop elected the Habsburg candidate Wisniowiecky (Mykolas I Kaributas Višnioveckis; 1640-1673). Of course, in the following year, he married Leopold's half-sister, Eleanor Maria, in a brilliant ceremony. Grémonville and the angry French MPs searched for allies among Hungarian conspirators, but their plans came to Lobkowitz's ear. The conspiring princes, Frankopan and Zrinski, voluntarily surrendered to the Viennese in

[308] J. Škofljanec, *Observanti*, Ljubljana 2008, 67-68.

[309] Note of Dr. Janez Šumrada on 9. October 2003.

April 1670, only a few months after the Auersperg's fall. The Croats did not get Auersperg's support and they were decapitated after a year-long hearing. Among the plans of the Zrinski-Frankopan conspiracy was the penetration of eight hundred conspirators led by the Brod na Kupi parish priest Juraj Prpinić across Kostel to Kočevje, where they hoped in vain for the support of Auersperg after the prince's dispute at the court.

The aggressive Colbert's Dutch trade policy forced enlightened Habsburgian emperor to take his action with countermeasures. In 1671, the French and Habsburgs signed a treaty of neutrality. The following year a Dutch war broke out, the first of three wars between Louis XIV and Leopold I.

5.2 First Carniolan Vacuum Researcher: Books on the Vacuum of the First Ljubljana Vacuum Researcher

5.2.1 Introduction

Modern vacuum technology began to develop when the mercury barometer and vacuum pumps were invented three and a half centuries ago. The basic ideas were probably Galileo's, and their performance involved at least seven stronger research groups, which were often very able but suffered in permanent mutual quarrels:

- The Galilean Circle around the Academia dei Lincei in Rome and then with Torricelli and Viviani's Florentine Academia del Cimento;
- Athanasius Kircher's (* 1602; SJ; † 1680) circle in Rome that began to flourish with Gaspar Berti (* about 1600; † 1643) in 1640 in a company with Torricelli, Nicoló Zucchi (* 1586; SJ; † 1670) and Gaspar Schott (* 1608; SJ; † 1666);
- Valeriano Magni at the court of the Polish king and in Regensburg (1654);
- Robert Boyle in Oxford and London with assistants Robert Hooke, Denis Papin and Francis Hauksbee (Huxbey, Hawksbee, * 1660; † 1713) in connection with the Royal Society experiments of Henry Power (* 1623; † 1668) in Halifax on 6/5/1653;
- Otto Guericke in Magdeburg in connection with the Prince of Ljubljana Janez Vajkard Auersperg in Regensburg (1654), then with Prince Philip von Schönborn (* 1605; † 1673) and Jesuit Gaspar Schott in Würzburg;
- Blaise Pascal's circle in Rouen and Paris with Florin Périer (* 1605; † 1672) at Clermont-Ferrand in the Auvergne region (1647) alongside with Mersenne's Parisian visitors like Etienne Noël (* 1581; † 1659), or even Descartes, followed by Henri Louis Habert de Montmor's (* about 1600; † 1679) Parisian group with Huygens in The Hague as the forerunner of the Parisian Royal Academy of Sciences;
- Londonese Franciscus Linus (Hall, * 1595; SJ; † 1675) in the Belgian Liege in 1661

Vacuum experimental innovations were spreading extensively across Europe devastated in the wilderness of the Thirty Years' War. White Ljubljana was by no means exempted: Slovenian vacuum technology can be traced through the paths of the main protagonists of vacuum research related to Janez Vajkard Auersperg's purchasing the main books on vacuum or testing vacuum devices. Most of the mercury of early vacuum researchers was mined up in Carniolan Idrija.

Among Carniolan compatriots, the most prominent was the Prince of Ljubljana, Janez Vajkard Auersperg, who arranged the Emperor's invitation for Guericke's Viennese visit; Janez was closely involved in the design of Guericke vacuum experiments in Regensburg in 1654. Guericke repeated his famous experiment with horses, which in vain tried to separate the hemispheres of emptied receivers in the court of Vienna shortly after the death of Emperor Ferdinand III in 1657.

Our prince was by far the most powerful in the imperial city of Vienna, where all those less wealthy had to leave the belly outside. The emperor Leopold I and Janez visited Schönborn and Schott's Jesuitical college in Würzburg in 1658.[310] Two years later the emperor in pleasant company of the empress moved to Ljubelj on 13 September 1660 and rode to the castle of Janez's brother, Volf Engelbert Auersperg, to get his bows of obedient inheritance from Carniolans. The Ljubljana Imperial visit was prepared by three

[310] Hellyer, 1998, 100.

brothers Auersperg: Janez Vajkard was the first minister in Vienna at that time, and the older brother Count Wolfgang Engelbert was the provincial chief of Carniola; also, their middle brother was not lagging behind, as he was the commander of the Karlovac Military Krajina Herbert from the Šrajbarski Turn near Krško. Herbert brought 150 knights from Karlovac in folk costumes accompanied by two whistlers and two drummers.[311] The unusual eastern colored music by the Auersperg palace was a pleasant view for eyes of everybody including the high society. For his emperor, Volf (Wolf) staged one of the first Ljubljana performances of the Italian opera at the time. The imperial messenger Lovrenc Kurelić (Churelichz) reported about the Italian Commedia and musica at Wolf's Garden, and later Valvasor noted it in his masterpiece Die Ehre (Glory).[312] Naturally, Valvasor watched enthusiastically and then painted the nice cavalry show in honor of the Emperor's visit. Unfortunately, we do not know whether on this occasion even the famous Guericke’s "horse" vacuum experiment was taken to Ljubljana.

The happiness is never eternal and soon after that, Janez’s luck began to decline. On December 10, 1669, they ordered him to leave Vienna within three days; the court intrigues pushed him from the sky above the empty space roughly against the solid ground! He had to go to his estate in Wels, and later he was permitted to return to his native Carniola.[313] In April 1670, the secretary of the academy del Cimento, the Count Lorenzo Magalotti of Tuscany (* 1637; † 1712), reported in Florence about the incessant attempts of the president of court chamber the Count Johann Quentin I Jörger Tollet (1624-1705) of the golden fleece order to arrange the return of Auersperg to the Viennese court.[314] The publication of Magalotti's letters was later purchased by the Jesuits of Ljubljana. The people of Ljubljana were left without a prince's prevalent word overnight in Vienna: how did they appropriately acquire knowledge of the modern vacuum experiments, the leading entertainment of the days?

During the development of their Ljubljana "prince" library in the middle of the 17th century, the Auersperg brothers were the most important in Carniola, often the first after the Habsburg rulers themselves. Such highest position was retained three centuries later. It is therefore particularly important to know by which ways and tools they advocated the advancement of experimental techniques and especially vacuum experiments in areas inhabited with Slovenians. Of course, the best example of their efforts is the Auersperg Ljubljana Prince’s Library, which was placed in their Baroque palace around the premises of today's NUK and kept the best private collection of books in Europe. In the 1668 catalog, rewritten in 1762 on 431 pages, there were as many as 3257 books in 6000 to 7000 volumes;[315] many of them were devoted to the problems of vacuum. The Auersperg’s Library catalog has long been considered a lost one until it was found in Vienna by dr. Matija Žargi and kindly made available to the author of this book.

5.2.2 Galileo and Kepler's Ideas in Auersperg’s Networks

Janez Vajkard Auersperg completed his studies in Siena in 1635 in the class of mathematician and architect Gallaccini. During his research of the vacuum Gallaccini was referring to the book of Benjamin Bramer, so he also directed Auersperg's thoughts to Bramer.

The most important Auersperg door for modern science were, of course, two thick parchment-bound books of Galileo's collected works in the first Bologna Manolessi edition from 1656. The edition classified Galileo’s works chronologically. It began with Galileo's proportional compasses as an ancestor of an analogue computer, which Auersperg also acquired in an older edition. This was followed by a Galileo’s defense in the conflict of interest involving the falsely claimed invention of Capra (1607), which was in Ljubljana and certainly in many other libraries bound together in the same volume with the book about Galilean Proportional compass’ drawing tool. After that paper, Manolessi published the second edition of Galileo's Paper about Water with numerous defenses against criticism. The first book was completed with Mechanics and Libra. The second

[315] Radics, 1878, 14.

book was launched by the Star Messenger, who brought fame to Galileo in 1610. Behind it, the editor added Sunspots, Comet from 1618, disputes with the Jesuits Scheiner and Grassi in various letters and finally the Discorsi with the foundation of the later Torricellian vacuum experiments.

Theophilus Gallaccini (* 22. 9. 1564 Siena; † 27. 4. 1641 Siena) was the son of poor respectable noble parents. At first, he devoted himself to philosophy and medicine and received his doctorate in Siena on 19 June 1583. He returned to Siena from Rome in 1602 and married a local beauty. In 1608 and 1609 he taught mathematics instead of Francesco Pifferi (* about 1548 Monte San Savino in Tuscany; O.S.B. Cam; † after 1604). In 1621, Gallaccini became a university professor of mathematics. After the death of the famous Guglielm Gangioli, Gallaccini also took over his lectures of logic and philosophy. His book on the architecture of ports, and his manuscripts on architectural theory were only printed in 1767. Gallaccini was very close to Galileo in his mathematical surveys, especially after Galileo's visit to the Sienese bishop in August 1633, immediately after the process in which Galileo was sentenced in Rome. Janez Vajkard Auersperg arrived in Siena a little later.

Manolessi did not include the disputed Copernican Dialogues of 1632 despite the death of Pope Urban VIII (Maffeo Barberini) in 1644, as the ecclesiastical authorities still feared the consequences of the Papal index. The problems remained for many decades, since Mayr did not offer Galilean works in Ljubljana in 1678. So, only Galileo's proportional compass in its first edition (1606) is still preserved in Ljubljanian libraries, while Il Saggiatore written against the Jesuits of Grassi in the first edition (1606) was acquired in Maribor, also in the first Roman edition of 1623. In any event, Auersperg had the opportunity to read Galileo's opus as the whole, since he surely did not forget to secretly look at his controversial Dialogues.

The father of Janez Vajkard Auersperg, Dietrich, studied in Tübingen only shortly after Kepler. Nevertheless, Auersperg did not buy much of Kepler's works. The family of Auersperg did not acquire neither the Mysteries dedicated to Kepler's friend Styrian governor (Landeshauptmann) Sigmund Friderik Herberstein, nor Rudolphine tables, not to mention the more Copernican-oriented Kepler's writings. Perhaps you would expect at least Kepler's Rudolphine tables, which were sold by Bookshop of Mayr in Ljubljana in 1678; however, the Auersperg did not store the Rudolphine tables in their library, unless they were cataloged in more than one hundred calendars listed at the end of the mathematical books list. Nowadays older Kepler works are not kept in public Slovenian libraries. Auersperg acquired the first edition of Kepler's optics from 1604 with the first mathematical treatment of the law of reflection and the vacuum interconnection space; he did not have other Kepler's works. In 1604, Kepler dedicated his optics to Rudolf II and laid the foundation for modern exploration of light. This Addition to Witello, the medieval Polish optician, Kepler wrote already in Graz, but then he indeed finished it in a hurry during his study of Tycho's measurements of Mars in Prague. He explained reflections of light as well as the operation of the eye and his own short-sightedness. At his Addition to Witello, Kepler frequently cited Porta to recognize the invention and even the first production of a relatively cramped Porta's telescope. According to Euclid's example, Kepler compiled his work full of assumptions, definitions, demonstrations, lemmas, and corollaries, since he already advocated Euclid's works in Maestlin's class in Tübingen in 1596, and he beloved such an approach. Kepler made a special table of his measurements of the solar eclipse in Graz on 30 June 1600/10. 7. 1600. The use of then popular wooden measuring device led Kepler to a more detailed study of optics.

Apart from Bacon's works, Auersperg did not buy books related to Londoner Royal Society, such as Robert Boyle, Hooke or Wren's notes on vacuum experiments. Similarly, we miss the works associated with the then new Parisian Royal Academy. Of course, both institutions were created in the era when Janez Vajkard Auersperg had just seen Abraham in his 50th year of age. Auersperg even obtained a polemical theology of Valeriano Magni. Magni and Pascal initially quarrelled over alleged priority rights of their invention of new vacuum experiments, but later they preferred to criticize the Jesuits jointly. In 1647 Magni showed vacuum experiments at the Polish court and published them in the book full of sharp critic of

Aristotle. Roberval charged Magni for plagiarism as Mersenne testified that he had personally informed Magni of Torricelli's experiments at their meeting in Rome.[316] In any event, Magni had to hear something about Torricelli's achievements during his Italian tour, which was the theme of the day after Torricelli's letter to Michelangelo Ricci dated 13 June 1644.

Magni wanted to be the inventor of Torricelli's vacuum barometric experiments at the National Assembly in Regensburg in 1654; there he met the Prince Auersperg, who was one of most relevant political stars of his era. He did not miss the mayor of Magdeburg, Otto Guericke, whose father, during his young years, carried out his duties for the Polish king. Guericke did not quite believe Magni's narrations, as he had already heard something about Torricelli's successes in the meantime. Magni as the first accurately described the passage of light through the air and through a vacuum,[317] and his criticism of Aristotle's rejection of the existence of a vacuum was the greatest challenge to the Jesuits of that time. At that time, Magni was at the height of his life, and as a Capuchin, he was not a pleasant interlocutor to the Jesuits.

Jean Rodolph Lefèbvre (Faber, * about 1580; † 1650) from Geneva became a professor of law and philosophy at Bern. In 1625 he published the Philosophy, which was purchased by Auersperg. The book was reprinted in the following year. He divided the physics in general and special kind. Those were still the sharply divided areas. The first, he described the rise in air pressure above the body, which is expected to accelerate its fall and further reduce the resistance of the air under the body. He described the siphon and the cannon project against the existence of a vacuum.[318] Even during the freezing of hot sealed water, Lefèbvre (Faber) attempted to solve the claim that the container would rather burst than to permit the existence of an emptiness.

Auersperg bought Melchior Cornaeus's (1598 in Brilon-1665 Mainz) Curriculum of Philosophy, which was offered to Carniolan customers by their new bookseller Mayr in Ljubljana.[319] The Jesuit Cornaeus retreated to France during the Thirty Years' War and taught philosophy in Toulouse for seven years. After returning to Germany, he taught scholastic and polemical theology in Mainz and Würzburg as a co-worker of ten years younger teacher of mathematics, the Jesuit Schott. He became a rector in Würzburg and then in Mainz. Of course, Cornaeus defended Peripatetic philosophy by remaking a new science together with Schott. With Schott's inherited vacuum pump, they also rebuilt a new kind of complementary science with the cautious remaking of Aristotle's ideas which later proved to be abortive anyway. Schott praised Cornaeus's careful study of experiments and in his Mechanica Hydraulica even reprinted some of the descriptions of experiments in the empty from Cornaeus's Curriculum Philosophia under the title Melchioris Corneai Diatriba de Novo Experimento. Among the twenty-seven Cornaeus's published works were his letters, which Kircher communicated to Iter Exaticum.[320] Schott discussed Cornaeus's views on the vacuum, at the very beginning of his first reports on Guericke's experiments involving the Prince of Auersperg, and those parts of a book certainly supported Auersperg's attempt to include eight Schott's works into Auersperg's Library, among them three in the joint bindings.

Auersperg's librarian, son of the mayor of Ljubljana Janez Ludvik Schönleben, included Schott's Mechanics among the books on architecture. There Schott reprinted Kircher's letter sent from Rome on 26 February 1656. Kircher discussed Cornaeus' hydraulics of "presumably" emptied receivers. Kircher offered a simple description of the supposed vacuum of another Jesuitical hydraulics expert turned astronomer Valentin Stansel (Estancel, 1621 Olomouc – 18 December 1705 Salvador Bahia in Brazil). In any case, Kircher insisted on Aristotle's ideas of opposing "vacuumists", as he was not able to escape the puzzles of disconnections and the problem of the impact of force (*Impetus*) in an emptiness. Kircher was convinced that even after pumping some air remained, while Schott nevertheless accepted Riccioli's compromised Galilean description of the weight of the air. Schott put some pages of beautiful pictures into his description of Heron's well and fountains.[321]

Janez Vajkard Auersperg obtained several Daniello Bartoli's books printed in Bologna where Janez Vajkard Auersperg studied from spring to autumn in 1633. Bartoli was seven years older than Janez Vajkard. His school benches were in Piacenza and Parma and he learned his theology in Milan and Bologna. Bartoli studied in Bologna in the class of physicist Riccioli who later also taught Janez Vajkard. Bartoli and Grimaldi served as Riccioli and Niccolò Zucchi's (1586-1670) assistants in their pioneering observation of the belts of Jupiter simultaneously discovered by EvangelistaTorricelli in 1630.

After his travels, Bartoli returned to Rome in 1650, where in his letters he repeatedly reported to his friend about the limitations in describing the physical truths posed by their Jesuitical order. Indeed, Bartoli became the leading baroque literati of Italian vernacular with his *L'huomo di lettere difeso ed emendato* published in Rome in 1645; Bartoli and Kircher were the Roman stars of the Jesuits also with their subsequent descriptions of China. Bartoli was a professor and rector of the Roman college. He repeated Pascal's measurement of altitudes with the barometer.[322] Despite the Jesuits like Linus,[323] Bartoli defended the pressure of the air contrary to the outdated conception of tension or even strangest fear of empty. He compared the evidence of the stresses in emptiness in the older theories of Torricelli's pressure above the vacuum; he accepted a modern belief.[324] Nevertheless, he rejected Magni's[325] and other philosophical explanations of the vacuum. Volf Auersperg did not buy this most physically colored Bartoli's book entitled the Tension and pressure (La tensione, e la pressione), which came out just before the death of his brother the prince Janez (John) Vajkard. In view of his cooperation with Guericke, Janez was particularly interested in the »substance« of vacuum; to the prince's lesser-minded heirs, however, the purchase of science of that kind may have seemed a little too deep. Janez probably himself ordered that Bartoli's book in its first Bolognese edition but he died on 13th November 1677 in the year when it was published, therefore he might not be able to read it carefully enough. The Friars minor observants of Ljubljana obtained the Venetian edition published next year which proved their early interests in vacuum experiments.

Figure 5-5: The first Auersperg Prince Janez Vajkard, after the appointment in 1654, was also commissioned to mint his own money as shown by the painting. On one side of his coin, he put his coat of arms, and on the other, of course, he engraved his own image. The silver coins proved to the last doubters that the vacuum plays really pays off)

Bartoli did not believe in the compressibility of water, which was convincingly demonstrated by Herbert and his pupil, the professor Anton Ambschell of Ljubljana, almost a century later. Bartoli mistakenly assumed that Torricelli had undergone his experiments in Florence before Berti's performance in Rome;[326] the historians did not correct the error until the middle of the 20th century. Bartoli's work on Geography was offered by Mayr in Ljubljana in 1678. Zois bought Bartoli's book about ice and its coagulation in its only Bolognese Italian edition entitled: *Ghiaccio e della Coagulatione.*

Kircher's student Lana Terzi was a member of the Royal Society of London; he corresponded, of course, to its secretary Oldenburg. In the year

Janez Vajkard Auersperg (Weikard, * 1615; † 1677) led the politics of Emperor Ferdinand III who was raised by the Jesuits and became even capable linguist and composer of the church music. After the death of Ferdinand II, Janez Weikard became a court councilor on 17 January 1640. A few weeks later he was sent to The Hague, where he became acquainted with Emperor Counselor the Count Otto Piccolomini and the secretary of the State Court Office Johannes Baron Walderode. Piccolomini was a member of the Fruchtbringende Gesellschaft, therefore Janez dedicated his memories to Piccolomini in Vienna upon his death. That memorial book was kept at the Auersperg Library in Ljubljana, while nowadays it is in a library in Wolfenbüttel along with eight Auersperg's almanacs and other works. As a member of the Fruchtbringende Gesellschaft, Piccolomini mediated with Janez that Janez should support Stubenberg's translation of the famous Francis Bacon, the first in the German language. Janez gave the Fruchtbringende Gesellschaft a magnificent and, of course, an expensive golden cup in 1657.[327] Bacon was, of course, the beginner of experimental thinking. His glory brought to him the respect of the Royal Society of London; unfortunately, his publications do not contain illustrations that were so characteristic of a later stance in physical experiments following the efforts of the Galilean Academy of Lincei. In the year 1654 the lower Austrian nobleman Stubenberg devoted a translation of Bacon's work to Auersperg a few months after the emperor's assignment of the title of prince to Auersperg. Stubenberg dedicated his translation of the other Bacon's work to King Friderick IV at the same time. Janez Vajkard Auersperg, during his collaboration with Guericke in vacuum experiments, became a knight of golden fleece, a conference and state minister. Are vacuum experiments, therefore, worthwhile?)

1670, he was famed for his description of aircraft carried by the emptied hollow copper metal balls; the idea obviously impressed Auersperg when he purchased Lana's book. It is less likely that Janez Vajkard Auersperg would also test vacuum balloons on the roof of his Ljubljana palace, as they were never successfully flown anyway.

[327] Bircher, 1995, 289, 297.

5.2.3 Guericke's Vacuum Experiments at Auersperg's Ljubljana Library

Janez Vajkard Auersperg acquired the first printed descriptions of Guericke's experiments published by the German Jesuit, Kircher's scholar Schott. Schott wrote most of his physics in his Interesting Technique dedicated to the Würzburg and Worms Archbishop the prince-elector of Mainz Johann Philipp von Schönborn, the same who bought a vacuum pump from Guericke a decade earlier. He donated that pump to the Jesuit University in Würzburg shortly before Schott began lecturing there.

Figure 5-6: The cover of the book of Schott's teacher Kircher issued in 1657, where Auersperg's librarian Schönleben specifically emphasized that it was a gift from Kircher himself. Auersperg had nineteen Kircher's books in Ljubljana; at least three of them were donated to him personally by Kircher, probably with the little help of Ljubljana Jesuits.

Auersperg naturally acquired Schott's book of the Pneumatic Mechanics with the first printed description of Guericke's vacuum experiments. Three years before Schott's edition, the newly promoted Prince Auersperg co-operated with Guericke's experiment in Regensburg in 1654.

Guericke corresponded with Schott but probably never met him in person. Auersperg also visited Schott in the imperial Embassy.

The Ljubljana Jesuits bought for their library in Ljubljana the more recent Schott's posthumously issued book entitled »the interesting techniques« for the founding of their studies of philosophy. Auersperg had it before. In this important book, Schott accurately cited early vacuum experiments in Europe and England, which particularly interested the first Auersperg prince. Schott relied on his Hydraulic-pneumatic mechanics and again rejected the existence of a vacuum.[328]

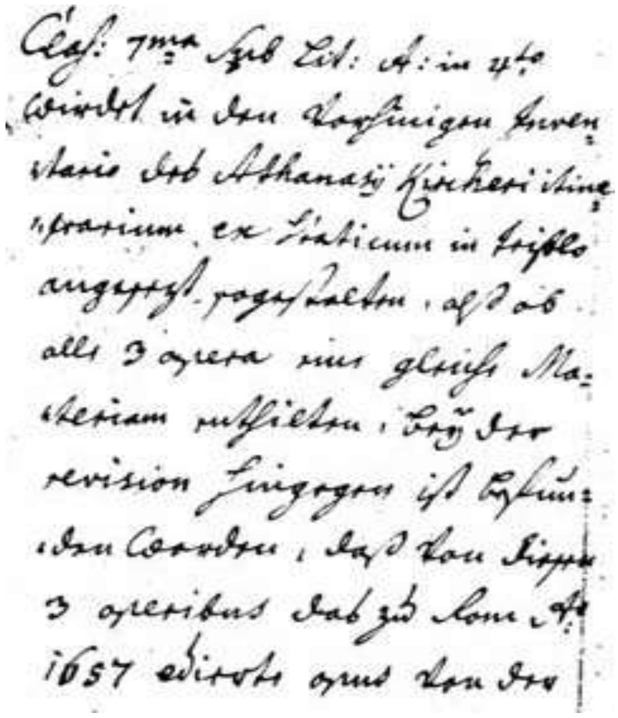

Figure 5-7: A catalogue of Auersperg's books, which on page 227 lists Kircher's (1657) work with its numerous vacuum discussions (1668, after the transcript from 1762, Vienna, Haus-, Hof- und Staats-archiv, Auersperg-Archiv VII, A / 14/4 (Minoritenplatz 1, Haus-, Hof- und Staats-archiv, Fürstlich Auerspergsches Archiv , VII Laibach, A 14/4 conv. 1 Laibach-Fürstenhof 1729-1895, Page 227).

Georg Philipp Harsdörffer was a member of the German Fruchtbringende Gesellschaft since 1642. His academical name used to be the Der Spielende which he used as a signature under his introductory glorifying poem on 2 + 2 pages to praise the patron Janez Vajkard Auersperg and even more Bacon Verulam in the translation of his fellow member of *Hochlöblichen Fruchtbringenden Gesellschafft* Johann Wilhelm count Stubenberg with academic name *Unglückseligen* in Nurnberg in 1654. Georg Philipp Harsdörffer studied law in Altdorf and listened to Schwenter's lectures. In 1652 he became a constituent, and from 1655 until his death, he was a member of the Nuremberg home counsel. He also worked on literature and music, especially in the *Der Grosse Schauplatz jämmerischen Mordgeschichten*, a collection of horror stories that Auersperg certainly enjoyed reading during the foggy Ljubljana winter evenings.

The first part of Deliciae, a book on fun mathematics and physics, was primarily Schwenter's work, although Auersperg's librarian attributed it to Harsdörffer. In 1636, Schwenter in his Deliciae described improvement of the microscope by twisting, modelled by the model of the human eye. In the same part, he described the fountain pen,[329] the numerous vacuum experiments and the flight of a bird filled with air.[330]

Daniel Schwenter (* 31. 1. 1585 Nürnberg; † 19. 1. 1636) was the merchant's son and studied under supervision of the professor Daniel Gelegengeim in his native Altdorf. Among Schwenter's professors was Johannes P. Praetorius (* 1537; † 1616), whose books were also purchased by Auersperg. Schwener became a professor of Old Eastern Languages and Mathematics at Altdorf University near Nuremberg. In 1626 he described measurements with proportional heights according to Galileo's model: Auersperg did not get it because he already had a dozen books on that thematic.

Harsdörffer added volumes 2 and 3 to Schwenter's Deliciae in 1651 and 1653. The library of Auersperg did not acquire them, but other residents of Ljubljana had both the first and the second edition. Harsdörffer was interested in Magni and Kircher's experiments with vacuum above a column of mercury, but he did not mention Guericke.[331] He described a popular Torricellian experiment of those times with a tube full of mercury, which is closed with a finger and then turned. He was interested in Magni's and

[328] Schott, 1687, 185-223, 255, 258.

[329] Schwenter, Harsdörffer, 1636, 1: 519-520.

Mersenne's experiments with Torricelli's vacuum, in Pascal's barometric altitude measurements, and in Bramer's vacuum experiments.[332]

After the death of his father, the sister took care of **Benjamin Bramer** (* 1588 Felsberg; † 1652 Ziegenhain). She was married to Bürgi. In the year 1604 Joost Bürgi (Jobst, Jöst, * 28 February 1552 Lichtensteig in Switzerland; † 1632 Kassel) took Bramer with him to Prague, where the young man remained for five years. From 1603 to 1612 in Prague Bürgi was Kepler's assistant hired for computing, dealing with logarithms and ballistics. Bramer published a book on a vacuum in Marburg. He designed an experiment like the later Guericke's; he considered the vacuum to be primarily the air that is squeezed out of bodies with water or fire.

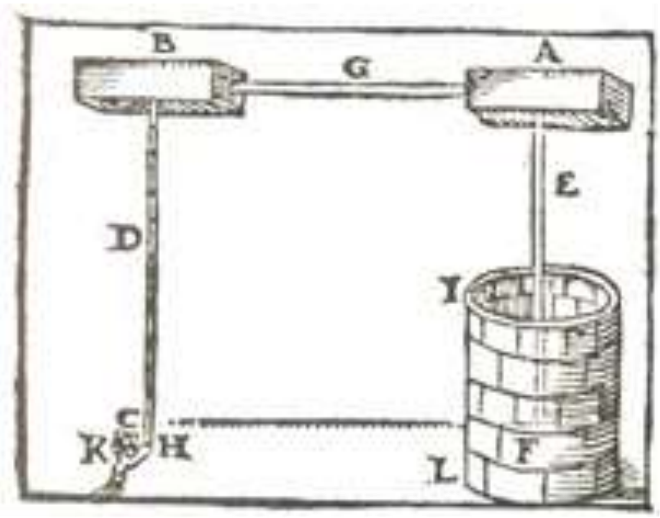

Figure 5-9 Schwenter's barometer with a pump (Schwenter, Harsdörffer, 1636, 487).

Figure 5-8: Schwenter fountain pen in the Auersperg Library (Schwenter, Harsdörffer, 1636, 1: 560).

[332] Harsdörffer, 1653, 3: 659, 466.

5.2.4 Conclusion

Within expectation, the first Ljubljana-Carniolan vacuum researcher procured numerous books on vacuum experiments. His interest in scientific experiments was crowned with his material support for the first German translation of Bacon's work, which allowed the penetration of new ideas also in Ljubljana.

5.3 First Prince Auersperg and the Capuchin Valeriano Magni

5.3.1 Introduction

Recently, the contribution of the Jesuits to the development of science, especially the early research of the vacuum, is most emphasized. The advantage of the Jesuits lies in the fact that today there are a quarter of them in the US while the American side of Atlantic is the most important source of research for the history of vacuum techniques. On the other hand, the contribution of the Franciscans, especially the Capuchins, was not much smaller, although the Jesuits were often in quarrels with Franciscans, especially regarding to the existence of a vacuum.

5.3.2 Rheita, Auersperg and Schönborn

Guericke produced the first pump in Magdeburg in 1648; that year officially ended the 30 years of war and started the 300 years of victorious path of vacuum techniques. Two years after the discovery, Guericke ordered to his servants to build a pump, which emptied the hemispheres for the famous experiment in Regensburg in 1654. The doubting Prince from Carniola, Janez Vajkard Auersperg assisted him. After a successful experiment, many bon vivant were interested in the purchase of a pump. Guericke sold the device to Prince Schönborn,[333] who offered him the most; he was the prince of Würzburg and Worms, and the archbishop-elector of Mainz, and he was not running out of the money at all. He did not buy the pump for himself but gave it to his Jesuit university in Würzburg. As early as June 22, 1655, from his journey to Mainz, Schott wrote to Kircher about the Guericke's Pump, before taking it along with the lectures of mathematics at the University of Würzburg in 1655/56.

Schönborn closely collaborated with Anton Maria Schyrl (Rheita, * 1597/1604 Reutte in Tyrol; OFMCap; † 14 November 1660).[334] Rheita invented the eyepiece for a Keplerian telescope and the binocular Telescope (1645),[335] which is still used today, unlike Kepler's variant. Rheita coined the term ocular and objective for the eyepiece and the lens, and even bothered to paint a map of the Moon (1645). The second edition of his Oculus Enoch was equipped with an addition.[336] On October 14, 1623 he matriculated to the humanistic studies of Ingolstadt University;[337] there he heard more about Tycho's merits, than about Copernican science.[338] That is why he defended Tycho Brahe's system of planets; of course, Tycho as an angry man with a mighty mustache under an artificial nose from an elephant's bone already passed away. Rheita ensured the existence of several satellites around Jupiter, Saturn and Mars (1643);[339] of course, other literati did not believe him much,[340] because at that time many other similar unproven ideas circulated among the scientists' networks. In later manuscripts Rheita described a geometric tube for the optical distance measurement, a periscope as the precursor of the panoramic telescope; he also did not forget to describe the structure of atmosphere on Jupiter with some funny guesses about the initial sins of the alleged inhabitants of Jupiter.[341]

Before his invention of the telescope, Rheita had long correspondence with Johann Philipp von Schönborn (* 1605; † 1673).[342] On 21 March 1651, he wrote to his brother Alberto, who was in the military service, about his binocular telescope, which he provided for Schönborn's collection.[343] Later, he clashed with Schönborn, so Schönborn's office in Mainz arranged Rheita's arrest in Brussels

on 21 January 1653.[344] After the inquisition process, Rheita was expelled to Ravenna;[345] his problems resembled the destiny of the other Capuchin V. Magni. The wealthy Schönborn was not particularly disturbed, so he arranged a private astronomical observatory in Würzburg and hired Ignacio Christian Bezold to this purpose.[346] This made Rheita's idea possible, as Rheita planned to set up his first European observatory equipped with the telescopes in Mainz,[347] which was earlier carried out only by Landgrave Wilhelm IV of Hesse-Kassel (1532-1592) and by Tycho Brahe.

5.3.3 Vacuum Experiments of Capuchin Valeriano Magni

Valeriano count Magni can be placed alongside Schyrl Rheita and Cherubin Le Gentil (Chérubin, * Orleans, OFMCap, † 1697) as the third famous Capuchin inventor.[348] Among the Capuchins served many other discoverers: the Capuchin Francis Marie Jablier has invented a photometer; the corresponding member of the Parisian Academy, Capuchin Emmanuel of Viviers, has compiled many popular microscopes and telescopes. Capuchin Chrysologus André designed the planispheres, maps and improvements to the barometer.[349] Galileo's correspondent Hilarius Altobello (Ilario Altobelli, 1560 (Montecchio (Treia) in Macerata-1637) published a map of stars which even Kepler used.[350] The Franciscans and Capuchins also made a great deal of missionary work, although Kircher, as a hostile competitor, did not attribute such importance to them as he did to Jesuit group of the Carniolan Bernhard Diestel, J. Gruber, and Albert D'Orville, who left Beijing in 1661 and headed for Lhasa in Tibet.[351]

The experiments had their early deep influences on the Franciscan view of the world, and it was brought to the highest point by Capuchin Valeriano Magni (Maximilian Magnani, Magnus, * 11. 10. 1586 Milan, OFMCap 25. 3. 1602 Prague;[352] † 29. 7. 1661 Salzburg), the most important Capuchin Baroque researcher of vacuum. Volf Engelbert Auersperg has even acquired Magni's polemical theology from Magni's mature years. Magni was born as the third child of the Italian merchant Constantine Magni (Costantino, 1527-1606) from Como. Constantino arrived in Milan in 1563, and worked in Vienna at an imperial secret council. He served Habsburg emperors, Maximilian II and Rudolf II. In 1588 he moved to the Prague Emperor's Palace and named his son by the ruler Maximilian. His name was kept until the gifted boy turned into Capuchin Valeriano.

Figure 5-11: Valeriano Magni around 1628, a few years before his vacuum experiments

Valeriano was a young Capuchin in Vienna from 28 August 1603 to 11 March 1605.[353] By 1605, he studied philosophy with physics included in Prague. [354] Valeriano briefly taught in Vienna (1613). He was sent to Linz[355] during the Viennese (1613) and the Prague plague. In 1614, he taught philosophy in Vienna, and in 1616 he went to Poland.[356] In 1619, he transferred to Linz as the Guardian and Master of the novices;[357] he met Kepler there.

Magni also supported Galileo's ideas in opposition to some Jesuits, which were quite bitter to such novelties, because the vacuum had gone into their noses. After short teaching in the Prague University, Magni became a Habsburg deputy in Paris (1622-1623); there he personally became

acquainted with leading vacuum researchers, including his two-years younger B. Pascal's father and the Minim Mersenne.

In 1623 he returned to Vienna as a definitor. Magni became a guardian in Prague,[358] where he soon became involved in a dispute with the confessor of Emperor Ferdinand II, the Jesuit Gulielmo Lamormain (Lamormaini), especially for Valeriano's opposition to the Jesuit takeover of the Prague University[359] where Valeriano got his support from the famous optician Marcus Marci. Valeriano also polemized with the father of modern education Jan Amos Komenski (Comenius, Komenský, 1592-1670), who under the pseudonym published the criticism of Valeriano’s theology in 1644,[360] and with the Cistercian Caramuel von Lobkowitz.[361] For a while, Magni even served as a Provincial of the Bohemian Capuchin Province (1624) until he became Apostolic Missionary in Poland, Hungary and the Holy Roman Empire of German nation in 1626; despite of the awkward name, the empire was also inhabited with Slovenians. In 1625, Valeriano was elected Bohemian provincial in Rome,[362] and in November 1627 he was in an audience with the emperor.[363] In Prague, during 1626-1628 he worked closely with the most important warlord of his time, Dietrich Auersperg’s classmate Wallenstein,[364] who was very interested in the problems of vacuum and other sciences. For that purpose, he hired a personal astrologer, Zenno.

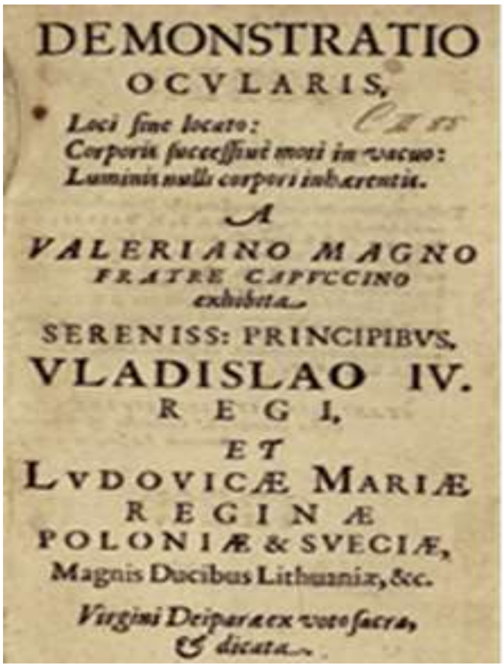

Figure 5-12: The cover of Valeriano’s book, where he first described the vacuum above the mercury column to explicitly advocate the vacuum.

Figure 5-13: The Parisian edition of Valeriano’s problems, which was followed immediately by Warsaw edition in 1647

Magni cooperated with the Cardinal Archbishop Ernest Adalbert de Harrach (Arnošt Vojtěch hrabě z Harrachu, * 1598; † 1667). He travelled with him from Prague to Vienna to visit the Emperor.[365] Magni established himself as an adviser to the Prague Archbishop Harrach (1622-1634), a later Cardinal. Valeriano tried to persuade the Galilean camp the Archbishop Cardinal Franciscus de Dietrichstein († 1636) who served as the Bishop of Olomouc from 1599.[366] Magni used his social relations among the Czechs to arrange the printing of Galileo’s Discoursi full of hints for vacuum experiments. Unfortunately, the cardinal passed away before the deal was accomplished up and the book was published by the Dutch. Magni tried to persuade the Cardinal Dietrichstein to publish Galileo's Discourse in the Bohemian Lands through his social contacts; unfortunately, the cardinal just released his sinless soul at that time and the book was only later published in

Leyden.[367] The clever Valeriano became familiar with vacuum problems at the same time. Thus, the young Valeriano was acquainted with the main innovations of the then science at an early age; Throughout his prolonged work, he acknowledged his Galilean description of the vacuum.

Magni's eruditions as the magnificent aspirations gave a powerful momentum to vacuum research within the Capuchin order, which Magni helped to establish in the Polish kingdom. In 1634, his early description of Protestantism was translated by the English. He was fierce and sometimes quite a passionate writer.[368] The Capuchins wanted Valeriano to be elected as their general, and the Polish king Vladislav (Ladislaus) wished to provide for Magni a nice red cardinal hat;[369] unfortunately, in 1643, Magni was not successful enough to collect enough support directly because of polemics about Magni's first edition of De luce mentium et eius imagine on 8. 9. 1642. Magni again met the influential persons at his visit to Rome three years later. Likewise, a quarter of a century later, a cardinal hat escaped the stubborn head of Wolf's brother, the Auersperg Prince Janez Vajkard. Volf Engelbert Auersperg acquainted Magni's polemics for his Ljubljana library; Magni's description of Protestants was published even in England in 1634. He became a famous polemical writer.[370]

On 8 April 1642, Valeriano traveled from Vienna to Graz and Ljubljana, then to Venice and Bologna, along with Fortunato de Tridento, Val di Sole († 1674). Fortunato was thirty years old Valeriano's companion, later a lay perfect of the Bohemian-Austrian province.[371] On 22 July 1643, Valeriano visited Gorizia and Trieste[372] in preparation for the Styrian provincial assembly, which included most of Inner Austrian places; the meeting was in May 1644, when Magni returned to Gorizia and Rome to meet the then Styrian provincial, the Guardian Silvester.[373] Thus, Valeriano was well acquainted with Kristof from Cividale (Čedad, * 1606; OFMCap 1623, † 5. 9. 1674). On 28 January 1664 (by the Gregorian calendar on 11. 2. 1664) Kristof carried out the first documented astronomical observation of the eclipse on the road between Vrhnika and Logatec.

When visiting the Slovenian places Valeriano, of course, lived with Capuchins and told them about his De luce and about planned vacuum experiments. As an experienced professor skilled in vacuum experiments, he also helped in teaching, since the Gorizia Capuchins led their internal philosophical studies with some intervals after 1591. The Bishop Tomaž Hren laid the foundation stone of the Ljubljana Capuchin church of St. John the Evangelist on April 25, 1607; in the quiet, he must have felt that it would become the largest in the then Styrian province. The Ljubljana Capuchins were mainly set up with a well-equipped well-known pharmacy, a bookbinding and the production of the monastery clothes.[374] In 1622 they established a library. Unfortunately, the French dissolved their monastery in 1809. It is said that Marmont's wife was angry after she supposedly caught a Capuchin's handkerchief on her nicely decorated breast during Capuchin's violent speech. In 1817 the monastery was demolished along with the church;[375] but the reports of the further fate of a fatal dirty handkerchief, unfortunately, are still silent.

In 1645, the Polish king Ladislaus (Vladislav) sent Valeriano Magni to Rome to prepare for the Torino Congress; the inspired Capuchin benefited the Romans by sharing with them his book De luce.

In the following year 1646, the Capuchin Magni independently carried out a Torricellian experiment on Ladislav IV's and Louise-Marie Princess de Gonzague-Nevers's Warsaw court. Queen's Secretary, Pierre Des Noyers, immediately informed French physicists of success. The Capuchin Magni set the barometer experiment next year for his Warsaw ruler Ladislaus IV and even more so for his bride, Louise-Marie de Gonzague, Princess Nevers (1611-1667). The queen's secretary, Pierre Des Noyers (* 1608; † 1693), immediately informed Roberval (4. 12. 1647)[376] and other French physicists from the Pascal's Circle of Magni's success. Valeriano himself wrote to astronomer and mayor Jan Hevelius in Gdansk (25 January 1648) and to the Parisian Mersenne

about his vacuum experiments (14 April 1648).[377] In Gdansk, Valeriano dealt with philosophical and mathematical experiments until November 1648, when he would return to Inner Austrian places of Habsburg monarchy.[378] Valeriano's physics was published in 1660 by his nephew, Filip's son Francisco Stephano de Magni Count Strážnice (Strassnitz in Moravia, † 1671). Valeriano's other brother František z Magni (František Magnis ze Strážnice, 1598-1652) was among the victorious Catholic commanders of the Battle of the White Mountain and established Piarists in Strážnice instead of Jesuits with a little help of Valeriano. The other unpublished manuscripts contained Valeriano's papers on vacuum, magnet, "physics of nonexistent bodies", the Solar system, arithmetic, geometry with the Sacrobosco sphere, telescopes, Galileo, Zaberella, Mersenne, Helmont and the vacuum researcher Pascal.[379] In his philosophical manuscripts with special chapters on vacuum, magnet and light with heat, Magni imagined round indivisible atoms like particles of bodies and a vacuum between them. Their movements should produce the energy.[380] The interest in science continued in Warsaw under the jurisdiction of Ladislaus' stepbrother the new king Jan Kazimierz. Kazimierz was a Jesuit and Cardinal before he married his stepbrother's widow Louise-Marie de Gonzaque. Nevertheless, Capuchin Magni, who did not like the Jesuits, supported the throne. Capuchin Magni heavily quarreled with the Jesuits. A few months after the dismissal of his first minister, Guericke's coworker the vacuumist Prince Janez Vajkard Auersperg, Emperor Leopold double-crossed Kazimierz and placed his imperial stepsister as the groom on the prestigious Polish throne. Eleonora was later considered a merciful widow. Mykolas Kaributas Wisniowiecki was the hero of subsequent Sienkiewicz's novels very popular in Carniola. Of course, as the new king, he married nice Emperor's stepsister Eleonora the next year, and poor Kazimierz soon waited for his last days in France.[381] Among Eleonora's courtiers was Alojzija, the daughter of Prince Janez Vajkard Auersperg.[382]

Magni and Pascal initially quarrelled for the championship for new vacuum experiments, but later they rather unanimously criticized the Jesuits. Due to the demand for priority of Valeriano Magni, in October 1647 Blaise Pascal hurried with his publication of the debate »*Novarum Observationum...*« (New experiments with the vacuum). At the same time, he wrote a preface to the book on empty (*Préface pour un Traité du Vide*), which was only partially preserved.

On July 12, 1647[383] Magni described his vacuum experiments in a book full of sharp critic of Aristotle and Aristotelian-friendly Jesuits; this was the first printed description of the properties of the vacuum over a closed mercury tube. In any case, while traveling through Italy, Magni had to hear something about Torricelli's achievements, which became a popular apple of dispute after Torricelli's letter to Michelangelo Ricci on June 11, 1644. The letter was of course secret and private, but soon everyone knew about its description of the vacuum above the mercury. Magni socialized at the highest class of Milano society, only a few hours away from Torricelli's Florence, so he should have heard all about such important news. Roberval has charged Magni with dishonest plagiarism, as he was told by Descartes's former classmate Parisian Minim Marin Mersenne (* 1588; OFMConv 1611; D. 1648) that Mersenne met Magni in eternal Rome and informed him of Torricelli's vacuum experiments in January 1645.[384] In any case, Magni had to hear something about Torricelli's vacuum experiment during his Italian journey, which became news of the month after Torricelli's letter to Michelangelo Ricci. After returning from Florence and Rome, the Minim Mersenne published a report on Torricelli's experiment in Paris in the spring of 1645;[385] in his monastic cell near Place Royal, he has acquainted the French with new evidence of the existence of a vacuum through a correspondent circle of his friends and visitors. He also talked about motions and vacuum with Hobbes and Descartes, who disliked the vacuums; Descartes liked to emphasize that his emptied glass is still filled with air. On 13 December 1647, René Descartes reported to Mersenne in Paris that he had put the paper

measure parallel to the Torricellian barometer.[386] The experienced glassblowers were needed for production of such glass devices; so, Mersenne could not carry Torricellian experiment in Paris, where he did not have competent craftsmen like Pascal had in Rouen. Shortly after Mersenne's death, his associates expanded into the beginning of the Parisian Academy of Sciences.

Figure 5-14: Jan Brozek published early critique of Magni from the Jesuit networks in Krakow in 1647.

Magni released his vacuum theory in July 1647, and in September 1647 he wrote and published an addendum.[387] Despite of his position in Polish court, Magni's ideas about vacuum were too much controversial to receive much support in Poland. On 18 July 1647 in Krakow, in his Peripateticus Cracoviensis productur de oculari demonstratione, contra Valeriani Magni demonstrationen ocularem de Vacuo. Vars., Jan Brozek (Joannes Broscius, 1585-1652 Bronowice in Krakow) from the University of Krakow, wrote against Magni as advocate of Aristotle. In 1620 during his studies of medicine in Padua Brozek corresponded with Galileo as a prominent biographer of Copernicus. Brozek was the best Polish mathematician of the 17th century and rector in Krakow in 1652, but he was also a sharp critic of Jesuitical influences in his university of Krakow in 1625, which eventually did not bring Brozek any closer to Magni's vacuum. The idea of an enemy of my enemy is my friend certainly did not apply in that case. A year after Brozek, Wojciech Kojałowicz (Albertas Vijūkas-Kojelavičius, * 1605 Kaunas (Kowno); SJ 1627 Vilnius (Vilno); † 1677 Warsaw) additionally criticized Magni. Kojałowicz taught philosophical lectures including physics at the University of Vilnius and became a rector there later in 1653-1655.[388]

In December 1645, Valeriano returned to Poland,[389] but he did not give up and wanted to be considered as an inventor of the barometer at the National Assembly in Regensburg 1653-1654.[390] Magni did not easily throw his chances away while he wanted to pose as the discoverer of Torricellian vacuum a decade later at the National Assembly in Regensburg (1654); there he met the Prince from Carniola Janez Vajkard Auersperg, the brightest among the then political stars. They did not miss the mayor of Magdeburg, Otto Guericke, whose father used to be a young delegate of the Polish king during his young years. Guericke did not fully believe Magni because in the meantime he himself has heard much about Torricelli's successes.

Magni gave his book to Guericke, proving the movement of bodies in a vacuum tube above mercury column in the second part of his book; in the last third part of the book, he accurately described the passage of light without a material carrier through the air and through the vacuum. Obviously, Magni did not love particles; he preferred waves, just like the vacuum researchers Huygens or Hooke. According to Guericke's report, he used a long tube of 6/4 Magdeburg cubits (Elle), which was clogged and filled with mercury at one end; they surely took it right from Idrija. When the opposite end of the tube was pressed with a finger, twisted and sank into the reservoir, the mercury slowly descended to a certain height of 5/4 cubits, which is today measured as 760 mm. The Magdeburg mayor Guericke, therefore, measured in cubits somewhat longer than 6 dm.

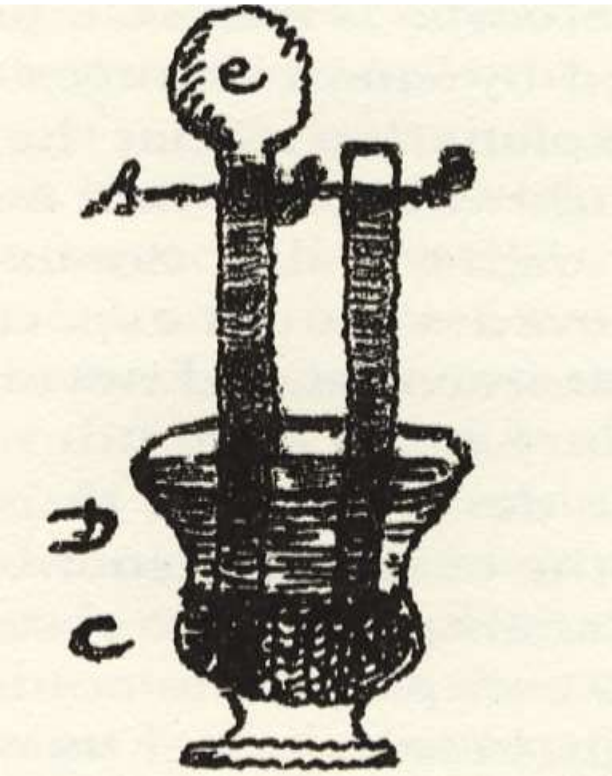

Figure 5-16: Torricelli named an experiment with mercury vacuum in a tube that was almost attributed to the inventive Cappuchin Valeriano Magni.

In any case Magni first described the light passing through the air and the vacuum;[391] by rejecting Aristotle's critique of the vacuum Magni became a black sheep for all the Jesuits, as he was not a Jesuitical sweetheart because he was a Capuchin.

[391] Guericke, 1986, 92-93, 108.

Valeriano watched an empty space in the tube over mercury, which was more rarefied than the vacuum which the mayor Guericke[392] was able to exhaust with his pump. As the most magnificent critics of Aristotle's rejection of the existence of a vacuum Magni was the greatest challenge to the Jesuit of his days. Magni was just at the height of his life path, but the Capuchin was not a pleasant interlocutor to the Jesuit. In 1659 Magni published a devastating Contra imposturas jesuitarum file against the Jesuits. Similarly, Pascal in his Parisian Provincial Letters humiliated the Jesuits; cautious Pascal did not sign up under his masterpiece because he was surely afraid to be caught by the similar impediments which dogged Valeriano.

Magni resented the Jesuit profoundly, especially with his criticism of Aristotle's denial of the vacuum. According to Aristotle, the four basic elements should have the natural direction of movement up or down according to their density. The emptiness has no density; so, Aristotelians were unable to determine the direction of its movement.[393]

Otherwise, the Pope Alexander VII (Fabio Chigi, 1599-1667) was very interested in science, but the daily politics forced him to condemn Pascal's letters and even Magni's vacuum. In 1661, following the advice of the Jesuits, he ordered the arrest of Magni in Vienna and his transfer to Rome.[394] The Pope Alexander VII was very grateful patron for sciences, but in that case, he had to follow the politicians. In 1661 the curia issued a command for the Magni's transfer from Vienna to Rome for the suspicion of heresy.[395] The Pope Alexander VII was quite grateful patron of sciences, but Magni proved to be too naughty even for Papal networks. Valeriano was called to Rome for defense; the magnificent Magni preferred to stay in the hospitable safe city of Vienna, even though by the Viennese proverb the belly had to be left outside. According to the advice of the Jesuits, the Papal Viennese nuncios issued an order for the Magni's arrest in Vienna and his capture in Rome; politics was just above science. Luckily, the Emperor Ferdinand III and his first minister, the prince of Ljubljana, Janez Vajkard, pulled out for

the unlucky Capuchin, who was apparently treading on corns of his mighty opponents. The hunted Valeriano rescued his head by moving to a more remote Salzburg, which was called by Slovenes since the ancient times as Solnograd; there he spent his last months in a monastery in a peculiar house prison, just like Galileo suffered previously in the suburbs of Florence. Shortly before his death, Magni went to Rome while all the ways were still heading to that eternal city; there, with his innate eloquence, he hoped to turn the rulers over to his empty vacuum theories. However, for those times, an old man's journey proved to be fatal; just before he caught his sight of the eternal city, he was visited by inexpressible fatal old woman called death.

Figure 5-17: Will it fall, down? The legendary rhetorical question of Minim Mersenne, who along with his aristocratic colleague fired a bullet from his vertically positioned cannon. Mersenne proposed that experiment in a letter to Descartes when he learned about the density of air, finally proved by vacuum.

Dobrzensky, who at that time had a great deal of clashes with the Carniolan alchemist Rain, believed in the Magni's championship in Torricellian experiments a decade later in his book on the New Philosophy of Fountains,[396] which was also purchased by Volf Engelbert Auersperg in Ljubljana; Valvasor collected other books of Dobrzensky at Bogenšperk. Naturally, the Czech Patriotism, which was not entirely foreign to the then educated people, could have been the cause of Dobrzensky's praise, although the networks were more geographically and ethnically colored in those times when Dobrzensky has severely

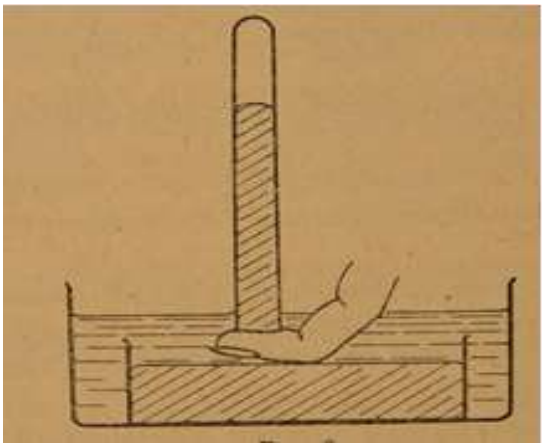

Figure 5-18: Magnified Magni's experiments in July and August 1647 with Hg under water, described on 17 September 1747 (Magni, 1959, 99) and published in the same year (Magni, 1959, 84-85).

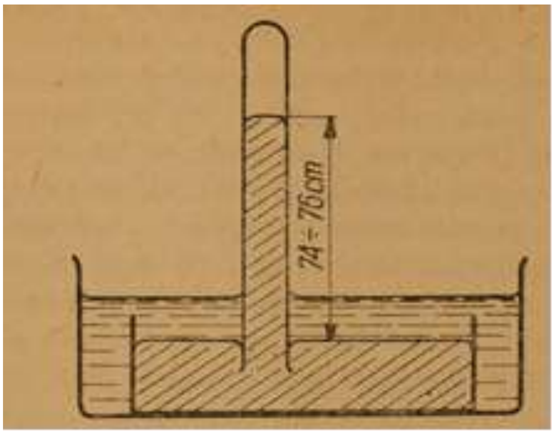

Figure 5-19: Magni's experiments 13-15 from 1650, published in the same year in Venice and in 1552 in Cologne (Magni, 1959, 89).

Figure 5-20: The vacuum researcher Magni on a death bed, painting in oil, which hung up to 1945 in Magni's castle Eckersdorf in the Glatz Midlands County (Bożków 9 kilometres south-east of Nowa Ruda). Later it was moved in the National Museums of Warsaw and Poznań (Nicolaus from Lucca; Ludwig from Salice, 1976, 128/129, 185).

[396] Thorndike, 1958, 8: 202-203; Dobrzensky, 1659, 25, 28; Cygan, 1989, 378.

quarreled with the Upper Carniola (Gorenjska) alchemist Janez Friderik Rain regarding the use of the philosophical stone. Even a century later the Carniolan Jesuit and the Ljubljana Rector, Anton Erberg from Dol near Ljubljana criticized the dead Magni, who obviously offended the Jesuits; with his description of the vacuum he pushed his thorn into their eye. Anton Erberg was still angry with the long-dead Magni, who obviously threatened the Jesuits' interests.

Figure 5-21: Magni on a deathbed, later inserted into the older Magni's theological work Iudicun (Vienna 1641) (Salzburg, Capuchin monastery) A copy from the Franciscan Assisi Museum (Nicolaus from Lucca; Ludwig from Salice, 1976, cover, 185).

Figure 5-22: Magni on a deathbed (Salzburg, Capuchin monastery. A copy in the Franciscan Assisi Museum (Nicolaus of Lucca, Ludwig of Salice in Italy, 1976, 132/133, 185))

Magni's thoughts about empty were the crown of disputes that had been dragging for over two millennia. The Jesuits who taught Aristotle's physics considered a vacuum as a concept which opposed itself. This was clearly felt in the Latin language, which happily sounded as empty as "locatum sine loco". Galileo's physics written in Italian language could avoid such verbal contradiction, but Magni (1647) turned that Latin proverb term with its head upside down onto the provocative title of his "locus sine locato".[397] Observations and experiments of the influential Capuchin have been based on modern vacuum theory. Because his experiments directly touched the ideas of Otto Guericke, his collaborator, the Prince of Ljubljana Janez Vajkard Auersperg and the other nobles of Carniola who were acquainted with Magni's ideas about the vacuum. That is why Janez Vajkard supplemented his own and his brother's library in Ljubljana with Magni's book; it is not improbable to say that the great writer Magni gave the book to Janez of Carniola, as did Janez's colleagues Kircher or Guericke.

Ad experientiam nuperam circa vacuum, R.P. Valeriani Magni demonstrationem ocularem et mathematicorum quorumdam nova cogitata, responsio ex peripateticae philosophiae principiis desumpta.

[397] Prager, 1980, 48.

However, the times have changed over the next generations while many have accepted Magni's description of the vacuum. What's more: two centuries after the death of its early promotor, the Capuchin Magni, the vacuum has become the basis of all modern technologies, from light bulbs to television displays.

The Frenchmen J. Pierius from Archiepiscopal College of Rouen in 1648 and E. Noël also rejected Magni, as well as the Italian Doctor of philosophy and medicine Johannes Elephantutius (Giovanni Scipione Elefantuzzi, Fantuzzi, † 14. 11. 1648) in his *Euersio. Demonstrationis ocularis loci sine locato, &c.: Pro vacuo imaginario dando in fistula vitrea Mercurio in ea descendente. Ab admod. R.P.F. Valeriano Magno editae.* He published his book in Bologna where he taught philosophy in philosophical college of the Bolognese Grammar School in 1648. The peripatetic Pierius witnessed and criticized Pascal's experimenting in Rouen.

The professor of Collège de France, Roberval, blamed Magni for plagiarism in 1647.[398] Noyers sent Magni's Book of 1647 to Mersenne.[399] On 5 November 1647, Magni sent to Roberval his defense against charges of his appropriating of Torricellian invention, describing his journey to Rome from 28 April 1642 to May 1643 and in beginning of 1645; he mentioned his Roman meeting with Mersenne, claiming that he was not told anything about the experiments and that he did not know Torricelli's success; he read Galileo (1638), the Archimedes' work on scales, the description of hydrostatic balance of Tytus Liwius Burattini (1617; † 1681) from Krakow and the writings of Hieronim Pinoccio (* 1612 Lucca; † 1676) who served as a mayor of Krakow in 1645-1649, as the secretary of Jan Kasimiersz and his deputy in the Netherlands and in England.[400] Magni was visited by the noble Aleksander Mazzi in Warsaw, and in 1645 by the Jesuit Jan Baptiste Adrianus, who left his Roman studies of rhetoric to came to Warsaw.[401]

In July 1647, Magni performed his seven stages of the experiment in front of the Polish king and his court. In the second phase, he pressed the mercury tube with his finger, turned it around and poured it inverted into the water, which spilled over a small bowl with mercury in a wider container. He measured 74 to 76 cm high column of mercury in the tube. Magni removed his finger to let the mercury pour from the tube into the bowl, while the water filled the tube to the top, where previously above the mercury he noticed few centimeters of vacuum. In the same year he described his experiments in Demonstratio. In February 1647, similar experiments were performed by Pascal in Rouen. In his booklet Vacuum pleno supletum (1650), Magni added experiments with an oblique tube that he pushed towards the horizontal position so long until it ran out of an empty space at the top.[402]

Magni's first published his twenty-four pages long booklet in 1647 or 1648. He put the question in the first subheading, and then he started a controversy with Aristotle. Magni's narrations were supplemented with the quotation of Galileo's Discorsi (1638),[403] and occasionally he also addressed his king and patron.[404] He then put Aristotle's name in the title of Magni's three chapters with which he concluded the book.[405]
The important new thoughts about empty were the crown of disputes that dragged already over two millennia. The Jesuits had a vacuum for a kind of entity opposing itself. This was also felt by use of the Latin language term sounding like "thing without space". Galilean physics published in Italian vernacular could avoid such a semantic contradiction. The apparent puzzle was also denied by Magni' title of his own work "space without things in 1647."[406] Experiments of Magni the Capuchin have been paved the way for modern vacuum theory. Since his experiments directly touched the ideas of Otto Guericke and his collaborator, Prince of Ljubljana, Janez Vajkard Auersperg, the other nobility of Carniolan were acquainted with Magni's ideas about the vacuum. That is why John Vajkard's brother supplemented their library in Ljubljana with Magni's book; the

writer-capuchin might gave a book to Janez as a gift.

Magni mostly resented the scholastic criticism after he refused Aristotle's denial of the vacuum. He wrote mainly against the Jesuit vacuum which served the Roman Inquisition networks of Honoratio Fabri (Faber, * 1606/7 Le Grand-Abergement between Lyon and Grenoble; SJ 1626 Avignon; † 1688 Rome),[407] whose vacuum seemed to be still full of vapours of mercury, just like Kircher or Linus' voids. Fabri was extremely popular among the Jesuits of Inner Austria with Ljubljana included. H. Fabri made similar experiments with vacuum between 1639-1641.[408] Magni mostly contradicted the scholastics with his criticism of the Aristotelian denial of vacuum. According to Aristotle, four basic elements should have a natural direction of movement upward or downward relative to its density. Unfortunately, there is no direction of movement of the empty vacuum[409] since it doesn't have a density. One hundred years later, the Carniolan Jesuit and the Ljubljana Rector Anton Erberg reviled the long-dead Magni, who obviously fairly stepped on to the Jesuits. However, the times have changed as the following generations have accepted Magni's description of the vacuum. What's more: two centuries after the death of Capuchin Magni the vacuum became the basis of all modern technologies, from the bulb to the television screen.

5.3.4 Marsenne Extends Knowledge of Vacuum

The Minim Mersenne, in his monastic cell near *Place Royal*, through his vast enormous circle of correspondents, told the French about Torricelli's vacuum experiment. After Mersenne's death, Mersenne's correspondents enabled Colbert to establish the Parisian Academy of Sciences. Mersenne became famous with his equation for calculating the of prime numbers, which proved to be wrong for the large numbers, but nevertheless encouraged many researchers. Mersenne corresponded with the vacuum deniers Hobbes and Descartes about the movement and the vacuum. Mersenne doubted that Galileo tested any motions of bodies down the inclined plane, but modern research has proved Galileo's reputation and his merits. In any case, Mersenne enabled the reception of Galileo's doctrine in the high society Parisian circles.

After returning from Florence and Rome in spring of 1645 Mersenne issued a report on Torricelli's experiment with a barometer in Paris.[410] On 13. 12. 1647 René Descartes reported to Mersenne in Paris that he had put the paper measure in front of Torricelli's type of barometer.[411] The experienced glassworks were required for production of such glass devices; so, Mersenne could not repeat Torricellian or at least Valeriano Magni's experiment in Paris because he did not have enough skilled masters there; much better happened to Pascal in the province.

5.3.5 Conclusion

The Jesuits made from Aristotle's science a barrier through their refusing to recognize the existence of a vacuum. The Capuchins were free of such clashes, so they received more novelties, which were offered by the invention of the barometer. The Capuchin Valeriano may not have been the first at his barometer experiments, but he was at least very successful in exploring the properties of the vacuum. He also visited his colleagues in today's Slovene places on several occasions during his official duties, and thus he also relied on newly advanced approaches to vacuum techniques to the erudite Slovenes.

5.4 Academic Ancestors of the First Carniolan Vacuum Researcher, Janez Vajkard, Prince of Auersperg

5.4.1 Introduction

Janez Vajkard Auersperg (Johann Weikhard, * 11. 3. 1615, the castle Žužemberk; † 13. 11. 1677, Ljubljana) was born four centuries ago; 370 years

ago, he became the first successful vacuum enthusiast in the areas of modern Slovenia. He was an assistant and simultaneously wealthy patron of Otto Guericke. At the same time, he supported the Jesuit researcher of the vacuum Athanasius Kircher and the first Viennese translations of Francis Bacon. Guericke and Kircher's opinions on vacuums were opposite, but they collaborated anyway. Janez Vajkard Auersperg undoubtedly played a key role in the beginnings of a modern new science, and especially for vacuum techniques among Slovenes, as well as among their then northern neighbors. His phenomenon is typical Slovenian. Like the entire row of subsequent educators in Slovenia from Žiga Zois through Valvasor and Fran Levstik, Janez did not even have official higher education; on the other hand, his early successes within top diplomacy enabled him to take over the most prominent Viennese political positions and above all to develop contacts with pioneers of vacuum technology in his mature years. And the Slovenian specialty: the modern Slovenes can easily welcome the "baron" Valvasor or Baron Žiga Zois among their compatriots, while most of their professional comrades and role models with Prince Janez Vajkard Auersperg included were declared as foreigners, even though they were Carniolans or even their fellow Slovenes as they were no more alien to Slovenian networks than Zois or Valvasor. They all wrote and spoke a little Slovene and preferred Latin or German; of course, Janez was speaking the Slovenian only in the dialect; he certainly did not use today's Slovene letters for his writings. This duality of criteria will be especially funny in the eyes of Janez's brother, the governor general Wolf Engelbert Auersperg, the principal extra-school educator of the teenager Valvasor. Both Auersperg brothers would not be able to close their mouths from surprise if in one way or another they'll learn that Valvasor was today a genuine Slovene, but not the Auerspergs! The modern thinker can by no means avoid the feeling that it is the transfer of later modern qualities to the former generations: because the princes Auersperg were bitterly opposed to the Slovene parties in the 19th and 20th centuries, the current Slovene politicians unduly transposed their "faults" to four centuries earlier Auersperg's ancestors. Here, perhaps, we have a surprise for you, dear reader: it is not the Slovenian stock of the poly-historian Valvasor or Žiga Zois perhaps connected with the fate of their own genus. The decisive point is that Valvasor family exist no longer in Slovenia, and the Zois family avoided the oppositions of Slovenian native supremacy policy? If we take a further step, would a possible descendant of the poly-historian Valvasor or Zois who would support foreign Germanization policy undermine the modern popularity of Valvasor's Slovenian stock or even the modern glory of his Glory? Valvasor really became popular among Slovenians on the national side, especially after his sons, because of his bankruptcy, went to the monasteries, and the offspring of their daughter enjoyed their bit of happiness abroad? In any case, it would be worth adopting at least the vacuum researcher Janez Vajkard, Prince of Auersperg, since he was undoubtedly Žužemberk native and Ljubljana used to be his home. In any case, his family lived in those areas of Turjak castle at least so long as the Slavic folks themselves.

5.4.2 Training during Studies

Janez Vajkard Auersperg was a member of highest Habsburgian nobility. Obviously, he did not study for an academic degree, but to socialize with the other future European rulers. Anyway, it might be interesting to name his teachers because they taught him Aristotelian physics which propelled his doubts in later Guericke's experiments.

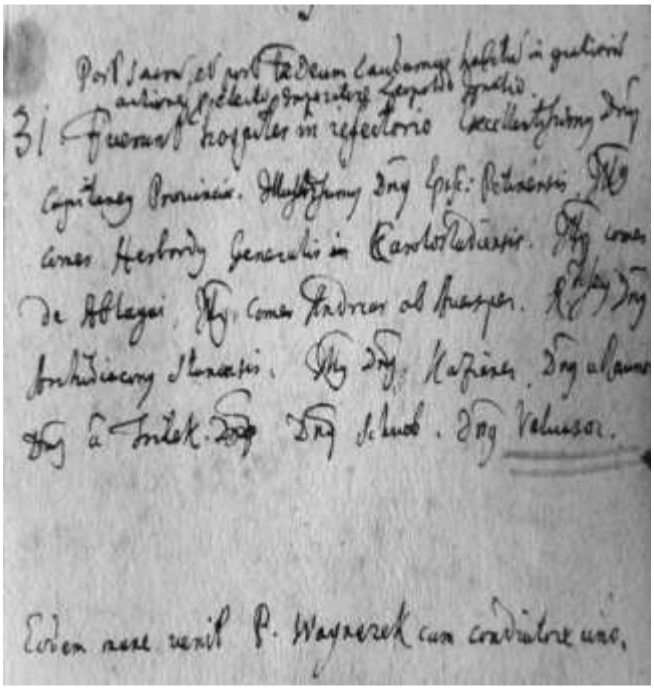
5.4.3 *Definition of the Time of Janez Vajkard Auersperg's School Days in Lower Schools*

In Janez's times, the Jesuits of Ljubljana offered six years needed for the lower studies: initials, basics, grammar, syntax, poetics and rhetoric; for the purpose of future priests, the Jesuits of Ljubljana also offered higher education studies in moral theology. Janez Vajkard did not complete his lower studies before the autumn of 1629, when he joined the higher (large) Latin congregation (Society) of the Assumption of St. Mary. He crossed over from the lower (small) Latin Congregation of the Queen of the Angels, which, however, has no preserved matrices. In 1628/29, a future vacuum researcher Janez studied syntax (higher grammar) as a member of the lower (small) Congregation of the Queen of the Angels, and therefore, in 1629, he entered the Latin higher Congregation of the Ascension as a future poetry student in the school year of 1629/30. It cannot be proven that the future first Slovenian vacuumist was included in the Congregation of the Death of Christ, which, despite of the earlier disputed beginnings, came to life well in 1660.[412] Also, of course, as a high nobleman, he did not join the German bourgeois Congregation of St. Mary. In this discussion, we will discuss vacuumists' school days in Ljubljana in 1620s.



Eodem mane venit P. Wagnerek cum coadiutore uno.

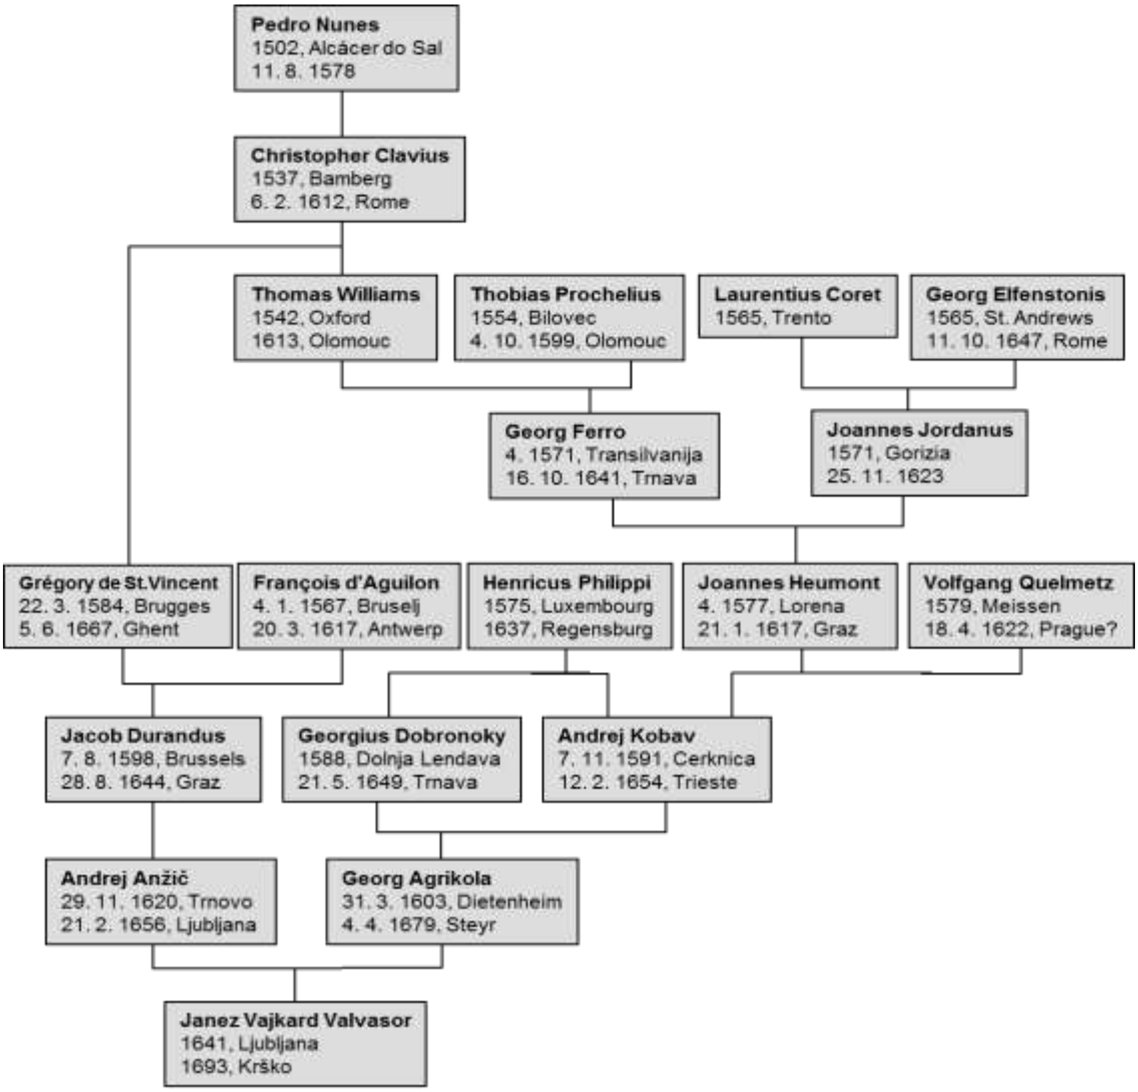

Figure 5-31: Academic ancestors' tree of prefect of the Ljubljana Lower School of Jurij Agrikola, who worked in Ljubljana during the time of Valvasor's schooling between 1653 and 1657; there are also the academic ancestors of his colleague Anžič.

5.4.4 The First Carniolan Vacuumist's Brother and his Friend Librarian Schönleben

As a son of Ljubljana mayor, Janez Ludvik Schönleben studied physics at the University of Graz in a class of a pupil Ch. Grienberger Hermann Horstus and Andrew Zergol from the Vipava Cross, who was also the student of Cerknica native Andrej Kobav. Schönleben’s and Warmuet's mathematics professor Filip Müller (Philip, * 1613 Graz) also came out of Kobav's long-standing Graz school as a student of the Belgian Jacob Honorat Durandus and, above all, of the Pole Sigismund Mogilnicki. Philip Müller taught law and mathematics to the Emperor, and as his confessor serving between 1654 and 1676, the accompanied the Emperor's visit to Ljubljana on September 12, 1660;[438] the high-ranking visitors were hosted by the first Carniolan vacuum researcher, Janez and his brother, the regional governor general.

The philosopher and librarian of Volf Engelbert Auersperg, Schönleben, was the prefect of the Ljubljana Jesuit lower school in 1650/51.[439] At the end of his prefecture, on June 22, 1651, Schönleben led the Ljubljana celebration of the anniversary of the Battle of Sisak,[440] which the 10-year-old Valvasor must have seen. Schönleben set up a school play named Heresis fulminata, followed by performances by the other patrons: the syntax lecturer Joachim Hating's under the title S. Janchorus Martyr in 1655, lecturer of rhetoric Andreas Anžič (Anšič) with a play about S. Pancratius (289-12 May 303 or 304 Rome) in 1655, and grammar lecturer Willibaldus Kogger with the tragic performance of Maria Stuart, the Scotia Regina in 1657 during Valvasor's schooling.[441]

As a priest in Ljubljana, Schönleben also worked closely with the Jesuits after leaving the Jesuit society, as he was often quoted in the Jesuitical diary. He left the society of Jesuits only to be able to remain in Carniola after a nearly twenty-years of Jesuitical experiences; traveling to exotic lands obviously did not please him too much, as it would certainly hinder his writing about Carniola. He was a frequent guest of the Jesuit college of Ljubljana where he encountered the teenager Valvasor. As a Jesuit in Ljubljana, Schönleben associated with a former Trnava physicist Harrer, who had just arrived in Carniola; together they visited Bled on 8. 6. 1651. Wilpenhoffer and Harrer visited Trieste together; Schönleben visited the Jesuit College of Ljubljana in May 1657, while Wilpenhoffer and Harrer visited Kamnik on 6 August 1657 and Kočevje on 20 September 1657.[442]

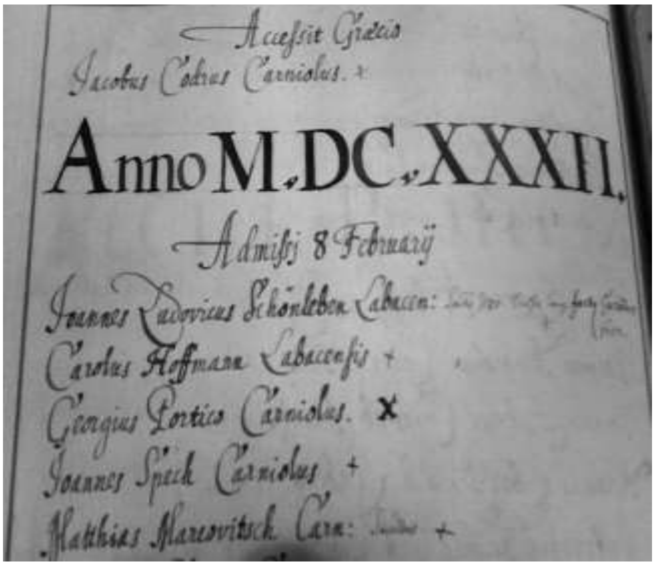

Figure 5-32: Schönleben became a member of the upper Latin Marian congregation-society in Ljubljana on 8 February 1632 (AS 1073 II / 51r paginated as page 122)

The well-dressed tables of the Governor-General Wolf (Volk, Volf) Engelbert Auersperg and his heirs were often attended by young Valvasor, Janez Danijel baron Erberg, brother of Valvasor's classmate Jurij Andrej Baron Gallenfels, Franc Hohenwart, Marko Grbec (Gerbec), the later provost Janez Krstnik Prešeren, and their older fellow Janez Ludvik Schönleben. From a fruitful exchange of opinions, even many fatal links have been coined: the owner of several books about vacuum, M. Grbec chose Ana Katarina Schwiz(en), the niece of Schönleben's nephew Janez Gregor Dolničar, for his second spouse.[443] She certainly loved her groom’s library full of vacuum data including Boyle’s *Nova experimenta pnevmatica respirationem spectantia* bind to Boyle’s *Exercitationes de atmosphaeris corporum*

consistentium: deque mira subtilitate, determinata natura, et insigni vi effluuiorum in Bolognese edition of 1675.

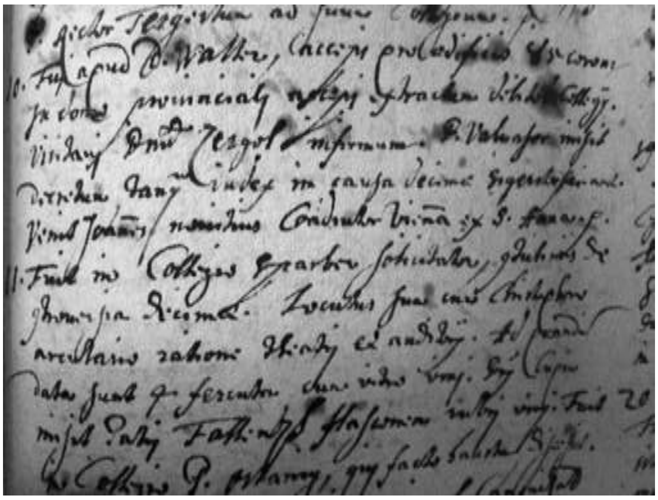

Figure 5-33: A note about the friend of the first Carniolan vacuumist, Valvasor, in the diary of the Jesuits of Ljubljana during the schooling of JV Valvasor on March 10, 1657. That’s the only note about Valvasor in the Jesuit journals, which might have been related to Janez Vajkard Valvasor, since the remaining three notes dated during his school years clearly report on the celebrations attended by Valvasor at headquarters of the Jesuits of Ljubljana together with other nobles of Carniola, and thus obviously referred to one of the older Valvasors. Ljubljana native Franz Zergoll von Zergollern (1613-4 May 1657 Ljubljana) as the husband of Felicita and the father of Franc Wilhelm from the later Gruber's castle Podrožnik (Mali Rožnik, Rosenbüchel), donated 500 guldens to the Jesuit of Ljubljana at the end of Valvasor's studies in 1657/58,444 so the record probably refers to him. The record does, however, only report 85 crowns in connection with the provincial’s fees and the weakened Zergol who died two months later. Valvasor is listed in relation to index and tithe. Immediately after Valvasor, Joannes was listed as a promoter of lessons of novices at the Jesuit Church of St. Anne in Vienna.

Wolf's palace looked like the then modern Italian academy; in fact, Wolf's young friends became the embryo of the academy Operosorum, founded in the year of Valvasor's death.[445] Many of Wolf's close friends were Academics Operosorum, such as Franc Hohenwart with the academic name "Innubus". On the other hand, Schönleben joined the Bolognese Academy of Gelati, like his nephew Janez Gregor Dolničar later in 1679. Janez Gregor Dolničar even enrolled in the Roman Arcadians in 1709.

The chief charm of the Wolf's Baroque table was certainly his rich library. At Wolf's time, at least Schönleben and Valvasor used it, which is why they soon gathered their own rich book collections.[446] Similarly, Janez Danijel Erberg, son of Auersperg customs officer from the Knežja Lipa of Kočevje region, was the grandfather of the Chinese astronomer Hallerstein and great grandfather of one of Carniolan most important owners of collections of books and antiques the baron Jožef Kalasanc Erberg; Janez Danijel had over 650 books.[447] Valvasor’s Bogenšperk played a similar role in the space of time between Wolf and the Enlightener Žiga Zois, although the local hospitable Bogenšperk network was not based solely on the well-being of the domestic library due to rural remoteness, domestic printing works and a collection of technical devices.

On 21 May 1626 the provincial governor general Volf (Wolf) Engelbert Auersperg became member and then secretary of the senior Latin Mary Congregation in Ljubljana, a few months after his transfer to the Catholic faith;[448] until then, he was Protestant, as his ancestors of Auersperg family were the main supporters of their subject Primož Trubar. Of course, Wolf's conversion to the Catholic faith was necessary, since as a Protestant he would not be able to study in Graz at all. On 9 February 1627 he continued his studies of poetry in Graz as the 104th student named Wolffgangus Engelbertus L. Baron ab Auersperg Dominus in Schemberg at the class of lecture master Stefan Kerezstes. The Bohemian Kerezstes studied philosophy with mathematics and physics in Olomouc, so many of his academic ancestors were numerous Bohemians and Poles, as Joannes Cadlovius. Among the most important academic ancestors of Volf Engelbert Auersperg, according to his Graz studies, was the Karst native Janez Rafael Kobencl, whose family has climbed up primarily through diplomacy as undoubtedly one of the most important in the empire. Contrary to the Auersperg’s family, Kobenzl’s family mostly

remained faithful to the emperor's Catholicism. In 1627, the prefect of Wolf's Lower School and the dean of linguistics was the Gorizian professor of physics Vincentius Amigoni (Amigoli). In 1657, the son of Wolf's cousin with the same name Volf Engelbert Auersperg studied rhetoric and later philosophy in Graz.[449]

Wolf continued his studies in Venice, Padua, Bologna[450] and Vienna. He completed his schooling in Siena at the class of mathematician Gallaccini after matriculation on June 15, 1630, like his younger brother, the prince Janez Vajkard Auersperg, who was able to listen to the lectures of famous astronomer and researcher of the gravity Riccioli. Janez' three years younger acquaintance Bolognese noble Grimaldi joined the Jesuitical society in Bologna on 18. 3. 1632, met his lifelong friend Riccioli there in autumn 1633 and later discovered diffractions of light. Among Gallacini's and Riccioli's classmates was also the famous Jesuit researcher of magnets and meteorology Niccolò Cabeo, whose book was bought by Valvasor.[451] Their teacher was a friend of Galileo, Giuseppe Biancani, who studied under supervision of the professor Markantun de Dominis. According to Newton's opinion, De Dominis was the main explorer of the rainbow; Dominis later left the Jesuit society, became a Senj-Modruš bishop, and then a Split archbishop. During his prolonged visit to the Protestant England, he was quite fond of Newton's predecessors. At the same time, he fell into the complicated wheels of the Inquisition, which, after his death, burned his books and remains on December 21, 1624, at a time when Volf Engelbert Auersperg still attended lower studies in Ljubljana.

5.4.5 *Wilpenhoffer Helps his Religious Co-brother Kircher's Correspondence with Carniolan Pioneer of Research of Vacuum*

After his studies among Italian scholars, Volf, returned to Ljubljana as a leading Carniolan politician. He supported his domestic Jesuits all over again. In contrast to the Jesuit mathematician Kobav or the Prague mathematician Gottfried Alois Kinner of Löwenthurn, the Jesuit of Ljubljana Wilpenhoffer sent to Kircher only the local scientific information that Kircher skillfully used in his descriptions of Carniola. Kircher never saw Carniola in person even though he was not far from it, since his journey from France to Rome could have ended in Vienna, where he was supposed to replace Kepler as an imperial mathematician in 1633. Wilpenhoffer also took care of the spreading of Kircher's works among the Carniolans, especially in favor of the regional governor Wolf Engelbert Auersperg. A few months after the release of Mundus Subterranei (Structura globis terrestris, Iter Extaticum II), on 24 October 1658, Wilpenhoffer reported to Kircher about the desire of the "Count, our lord" to have that book. In fact, Wolf's librarian Schönleben entered Wolf's bookplate in the title page of that book in the same year 1658.

Wilpenhoffer supplemented Kircher's knowledge of Carniola; Kircher initially did not mention either Idrija or Cerknica Lake in his book, although he reported on the waters between the Alps and on silver and minerals below them in the Alpine Hydraulics chapter.[452] He described the Danube river[453] in more detail and discussed the properties of mercury.[454] Wilpenhoffer reported to Kircher on a mercury mine, without naming Idrija; he noted that they also have a "fossil silver" wire there. In relation to the mine, he quoted Casati's book Ex Ligna, which was one of the books of the Jesuit Paulo Casati or the earlier work of the other Jesuit Albert von Curtz (Curtius, pseudonym-anagram Lucius Barrettus, * 1600 Munich; SJ 1616; †19. 12. 1671 Munich). Casati's *Geometricum problema ad lineas cuicunque rectae datae aequidistantesc* was published in Milano in 1602. Kircher paid special attention to the lake "near the place called Cerknica", which completely sinks underground and allows plowing over the dried field and even the hunting. Over time, the water from the bottom again bursts its banks and flooded the fertile field within the pond. Kircher relied on Wilpenhoffer's instructions.

Eleven years later, Wilpenhoffer wrote again to Kircher from Ljubljana to Rome on 28 November 1669. The letter was shrunk on the bottom; the last

half of report was written in much smallerletters, as if Wilpenhoffer was not supposed to start the other additional page on another leaf. He first mourned the death of Karl Watoser, probably their common Jesuit acquaintance outside the Austrian province, and then reported on two parts of Kircher's Ars Magna sciendi seu combinatorica under the abbreviated name Ars combinatorica. This book also inspired Wolf "Count the Excellency the

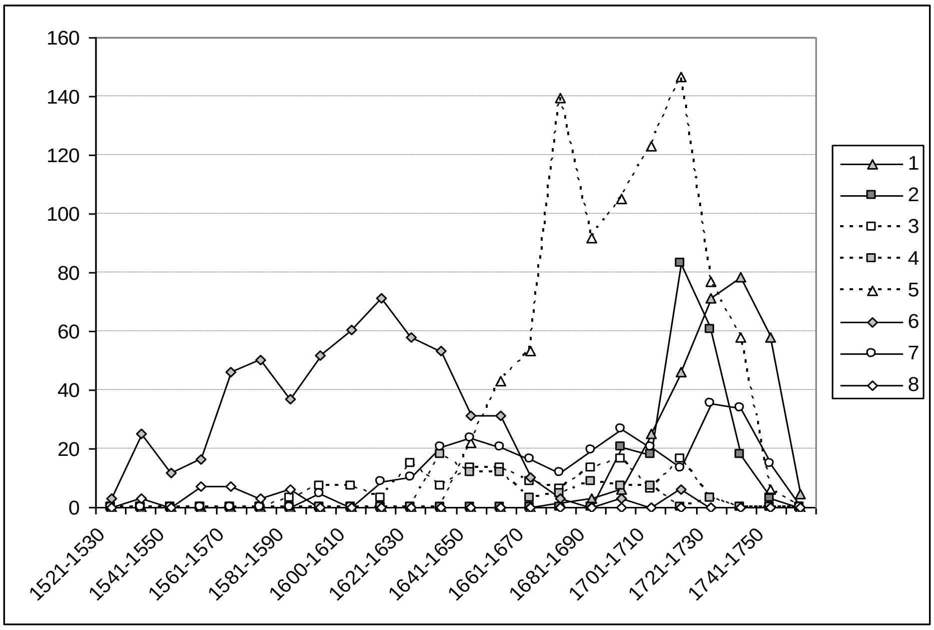

Figure 5-35: Changing the ideas of physics of the 1480 Jesuit professors of mathematics and physics from the Austrian and Bohemian provinces plotted along the decades of their births. (1 Bošković's supporters, 2 Cartesians, 3 Aristotelians, 4 Riccioli's North Italian networks; 5 Newtonians including the Jesuits Paul Hansiz (1645-1721) and E. Vols, 6 Clavius' networks including the Belgians D'Aguillon, Tacquet, Theodorus Moretus, 7 The researcher of vacuum Kircher and his students Lana and Casati, 8 Kircher's collaborators)

Governor of the Province": only recently he was elevated to the title of the Excellency as the new Imperial Secret Councilor. Wolf received that work printed in Amsterdam in 1669, and Schönleben catalogued it into a professional group of linguistics. Contrary to other three Kircher's books, in Mundus Subterranei and Ars combinatorics Schönleben did not note that it was a gift from the writer. This may mean that Wolf had to buy both prints; Wilpenhoffer certainly acted as a facilitator.

Kircher explored Carniolan waters without visiting those places. He never saw Lake Cerknica,[455] but used notes of his fellow Jesuits as Kircher's Museum in Rome was a gathering place for all kinds of Jesuit discoveries and reports. Before Wilpenhoffer, the greatest Kircher's Inner Austrian reporter was his fellow Jesuit Sigismund Siser (Siserius, Siserus, * 1.
5. 1636, Klagenfurt; SJ 7. 10. 1653, Leoben; † 29. 12. 1693, Vienna). Kircher reprinted Siser's letters in his Iter extaticum II Qui et Mundi Subterranei (1657),[456] which almost forced Wilpenhoffer's additional reports on Idrija and Cerknica for the later release of Kircher's Mundus Subterraneus.[457] After he joined the Jesuits in 1653 and spent his novitiate years in Leoben in 1655-1656, Siser may have stayed among the Jesuits of Ljubljana, although without official office. In 1656 he voted for the Jesuits of Ljubljana 800 guldens from his legacy; the Carinthia provincial States general, in fact, sent out 500 golden dinars from this account to the Jesuits of Ljubljana in 1658. Siser's attachment to the Jesuits of Ljubljana was also the result of a fall from the horse of the Ljubljana student of the casuistic Janez Siser (* 1 July 1608; † 1636) from Velikovec (Völkermarkt) in Carinthia near Klagenfurt, who died in the Ljubljana college on the day of the birth of his relative Sigismund Siser. Between 1657 and 1659 S. Siser studied at Kircher's class in Rome;[458] so, he brought fresh news about Carniolan attractions to the Eternal City. During the years 1670 and 1673, Siser lectured on ethics and philosophy in Vienna.

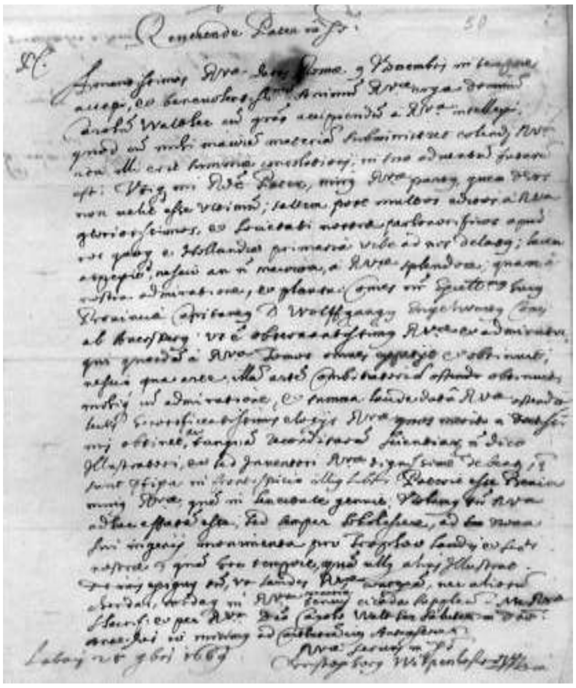

Figure 5-36: Wilpenhoffer reports to Kircher about Wolf's praise of Kircher's book Ars combinatorica[459]

Among seventy-five Jesuitical master's and priests of Valvasor's school days in Ljubljana there were altogether five teachers of mathematics (7%) and 16 professors of physics (21%); among them twelve (16%) published their works (Francis Menegatti, Janez Rover, Kobav, Montegnana, Souttermans, Schönleben, Preischaff, Dillherr, Söldner, Jelenčič, Lindelauf, Rainer). Only the first four wrote also on physics and mathematics, among them in Celje resettled Ljubljana native Montegnana. Montegnana wrote about the square of the circle, magical quadrangles and other entertaining problems in four chapters[460] at the time when he was still in charge as the confessor of the deposed minister Prince of Auersperg. Valvasor did not acquire the books of the Jesuits of Ljubljana who taught there in his schooling times, except the works of Schönleben and Friderik Jelenčič, who both left the Ljubljana college in the summer of 1652.[461] Apart from Hermann, Jelenčič, Schönleben, Montegnana and Kobav, Dolar was the only one among the Valvasor's professors of Ljubljana noted in Valvasor's book Glory (Slava), except for his list of rectors. Of course, Valvasor

also mentioned some of the other Carniolan Jesuits among his list of local writers.[462]

5.4.6 *The Confessor of the First Carniolan Vacuumist*

The confessor of the first Carniolan vacuumist, the noble Montegnana, was a kind man, a trusted collaborator of his patron Janez Vajkard Auersperg. He was among the most famous of his species. The confessor of Auersperg, the Jesuit Ferdinand de Montagnana (Montegnana), was the grandson of Trubar's archenemy Polydor Montagnana († 1604) and the son of Severus (* about 1579; † before 1602). His cousins were the Jesuits Francesco Harrer and Janez Jakob Harrer, sons of the Preddvor castle owner Felicitas Montagnana and the court judge Sebastien Harrer of Carniola. Polydor became a noble member of the Carniolan province Estates General on 3 June 1592 in Gorizia; eight years later he donated organ musical instrument worth 400 golden coins to the Jesuits in Ljubljana and in 1605 he founded a scholarship for two students. Trubar was the subject and friend of the ancestor of the first vacuum researcher Auersperg, who would surely be surprised by the vacuumist's choice of confessor after Polydor proved to be so hostile in his times.

Ferdinand de Montegnana completed his lower school in Ljubljana by studying rhetoric in 1615/16. With the recommendation of the Ljubljana Rector the Pole Nikola Jagniathovius (Jagniatovič) on 27 December 1616, he was accepted to the Graz seminary of Ferdinandeum, where he studied mathematics at the university together with Andrej Zergoll on 3 January 1617 and on 3 February 1617. Next year 1617/18, he studied physics in Graz. In 1619/20 he studied rhetoric in Vienna in the class of Viennese Ferdinand Mengenhauser (Mengerhauser) together with Andrej Tullius Bernardini from Ljubljana. While their three classmates continued mathematical-physical studies in Graz, the Jesuits sent Montegnana, Bernardini and Graz native Valerio Schörckel to Italy. Thus, between 1620 and 1622, Montegnana was educated at the Jesuit college in Sicilian Messina, where in his times the legendary Greek Francesco Maurolico (* 1494; † 1575) taught. Francesco Maurolico was the son of the Constantinople guy who did not love their new Ottoman rulers there. The Benedictine Maurolico, along with other Byzantine fugitives, presented to the Europeans the ancient Greek language, thus paving the path for the vacuum experiments of Torricelli and his heirs. Among the publishers of Maurolico's works were the Roman mathematician Ch. Clavius, Giovanni Giacomo Staserio (* 1565; † 1635) and Vincenzo Carnava († 1615) from Messina. At the time of Montegnana's education, Galileo, with his Copernican stance, began to oppose the Vatican's mighty men, after being cruelly crushed by the Jesuit astronomer and architect Orazio (Horatio) Grassi. Immediately after completing the study of mathematics-logic, physics and metaphysics, Montegnana returned to Ljubljana together with the Istria native Leonard Bagni (* 1593, Pazin; † 1650, Zagreb) as a lecturer of the first classes in Ljubljana, full of impressions of the new Italian sciences, the beginnings of vacuum technique and quarrels about the motion of the Earth. Montegnana's older companion Bagni finished his studies in Rome. Perhaps, this was precisely why he carefully dictated his lectures to his graduate student of physics Graz native Jurij Winkler, in which he adhered to Aristotle's guidelines in dealing with the vacuum in 1628. When Montegnana occupied the Ljubljana teaching position for the third time, after the Emperor's death on March 23, 1637, he performed a famous festive speech in the Ljubljana cathedral, which he printed in Graz on 44 pages and dedicated his first pages to three young brothers, the Counts of Auersperg: the future regional governor Wolf Engelbert, the prospective General Herbert and the future prince of the vacuum experiments, Janez Vajkard. His contribution was addressed as: Oratio Funebris ... Labaci ... Ferdinandi II. That oratorial performance opened his door to the diplomatic work of Janez Vajkard Auersperg, who was just then preparing a peace treaty after a devastating Thirty-year war. Thus, in 1642 Montegnana was sent to Spain to accompany the imperial mission. In 1661, as a prefect of the Ljubljana School, he wrote reports for the provincial.[463] He was precisely the kind of priest whom the vacuumist Janez Weikard (Vajkard) needed; shortly after the end of his experiments with Otto Guericke with a vacuum pump in Regensburg in 1654, Janez wished to use Montegnana's experience with Italian science and

[462] Valvasor, 1689, 2/6: 353, 357, 358, 359, 365, 367, 8: 713.

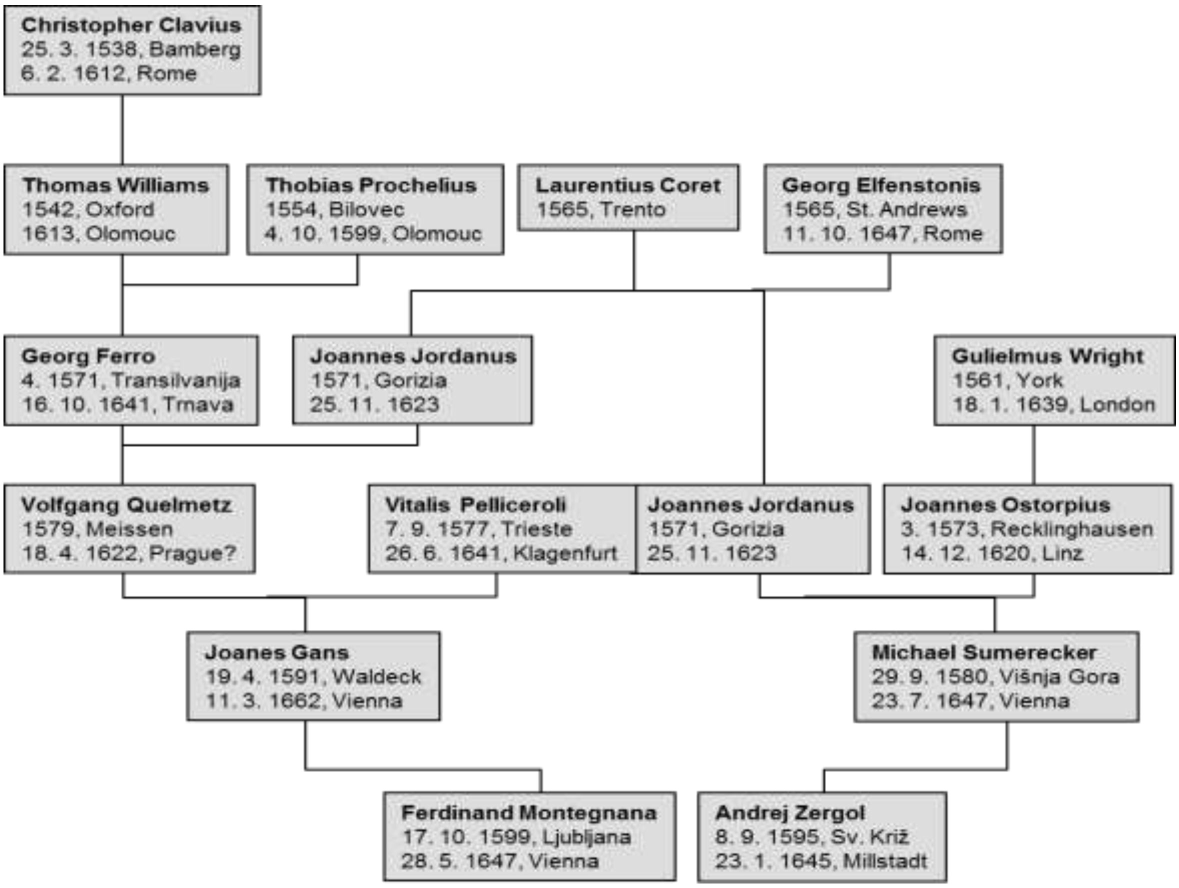

Figure 5-38: Academic ancestors of Montegnana and Zergoll by Their Graz Studies in Logic-Mathematics

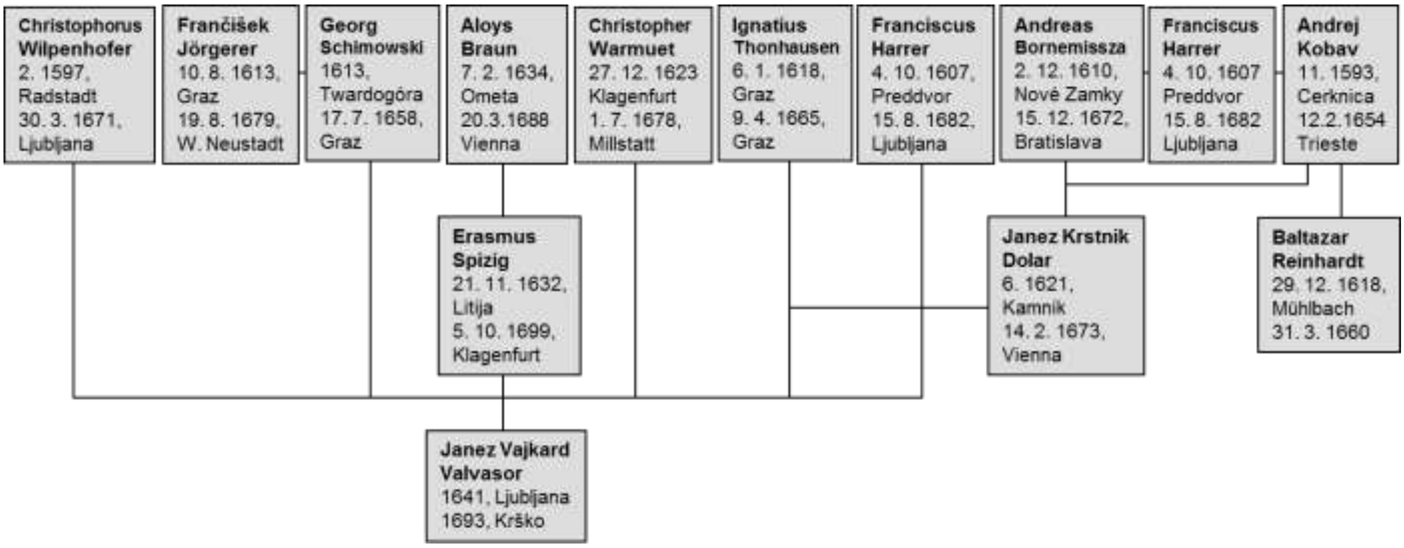

Figure 5-39: The Jesuit teachers in the time of the studies of the namesake and coworker of the first Carniolan vacuumist, renowned Janez Vajkard Valvasor

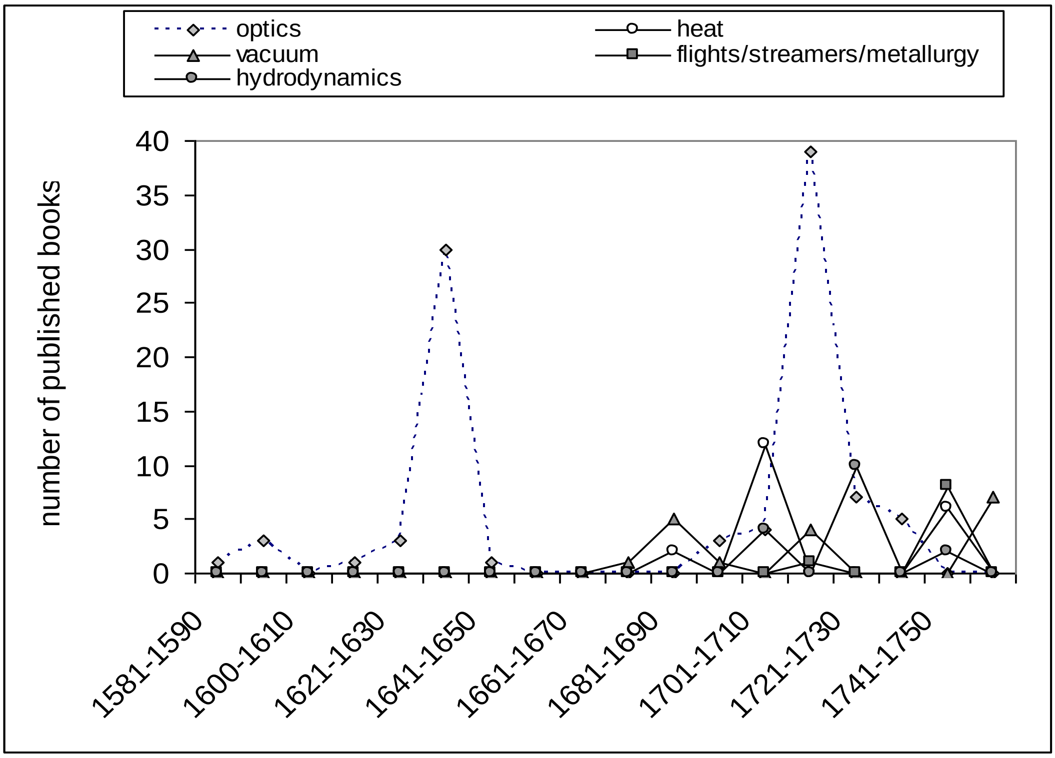

Figure 5-40: The number of published books about physics authored by the Jesuits of the Austrian and Bohemian provinces, out of a total of 601. Among them, thirty-six were authored by the Jesuits who taught physics and / or mathematics in Ljubljana.

chose him as his personal confessor in 1664. Their cooperation was mainly about science, until the prince vacuumist fell of the imperial favor in the last weeks of the year 1669. He soon had to return to his Carniolan home, where Montegnana did not dare to follow him. Nevertheless, in 1673, Montegnana published anonymously his joint designs about the squaring of the circle. The only well-known edition with a similar title is attributed to the bibliophilic count Bernard Ignátz Martinitz (* 1603; † 1685).[464]

[464] Valvasor, 1689, 2/6: 353. Baraga, 1999, 103 and Simoniti, 1972, 89 put the year of printing 1637 to Graz or to Ljubljana.

The prince vacuumist Janez replaced the absent Montegnana in Ljubljana with the local Jesuit teachers of his children. First, in 1674, he selected the Viennese professor of Logic Karl Boranga (* 1640; † 1684), a former student of Tolmin native mathematician Janez Krstnik Cruxilla (Križanič), who had just returned from Madrid. Karl has spent his last five years as a missionary after Janez Vajkard Auersperg's death. Initially, he converted the natives of Mexico as the precursor of Marko Kappus, and then sailed to the Philippines and to the Mariana Islands. After Boranga, Janez chose his own namesake Austrian Nexinger (* 1641

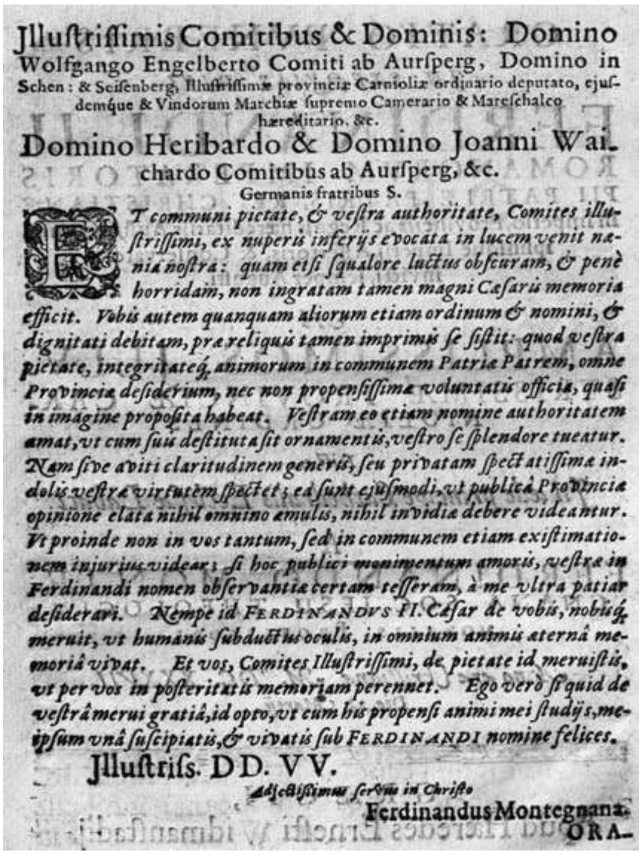
Figure 5-41: Record of the entry of the future confessor of the first Carniolan vacuum researcher Ferdinand de Montegnana to the High Latin Marian congregation-society under the chairmanship of professor of rhetoric Valentin Koch (Cochio) from Duderstadt, east of Göttingen, on 8 September 1614 (AS 1073 II / 51r pp. 76, 78). Two other younger future Jesuits, Montagnana’s two years younger guy from Ljubljana Lovrenc Kogler and the Škofja Loka native Janez Jakob Scriba, entered the society together with Montagnana. A note was promptly added upon Montegnana's three-year later entry into the Jesuits’ society and on the conduct of congregations. Valvasor also had him for a Ljubljana native in contrast to more relevant records that considered the subsequent relocation of the Montegnana's family to Celje.

Schwanenstadt in Upper Austria; † 1729) as Auersperg’s home teacher in 1675/76. Nexinger used to be a student of Solkan mathematician Philip Ceferin (Zeferin, Čeferin). Following the prince's death, Nexinger lectured on physics in Trnava and Zagreb. Nexinger was able to present the newest advances in vacuum techniques at Janez Vajkard Auersperg's Ljubljana palace. The ideas related to vacuum which circulated in Ljubljana of the prince Janez Auersperg’s era were mainly connected with the vacuum balloons that Kircher's student from Brescia, Francesco Lana Terzi, described immediately after Janez Vajkard Auersperg's return to Carniola.



Illustrissimis Comitibus & Dominis: Domino Wolfgango Engelberto Comiti ab Aursperg, Domino in Schen: & Seisenberg, Illustrissimae provinciae Carnioliae ordinario deputato, ejusdemque & Vindorum Marchiae supremo Camerario & Mareschalco haereditario, &c.

Domino Heribardo & Domino Joanni Waichardo Comitibus ab Aursperg, &c.

Germanis fratribus S.

ET communi pietate, & vestra authoritate, Comites illustrissimi, ex nuperis inferijs evocata in lucem venit naenia nostra: quam etsi squalore luctus obscuram, & penè horridam, non ingratam tamen magni Caesaris memoria efficit. Vobis autem quanquam aliorum etiam ordinum & nomini, & dignitati debitam, prae reliquis tamen imprimis se sistit: quod vestra pietate, integritateq. animorum in communem Patriae Patrem, omne Provinciae desiderium, nec non propensissimae voluntatis officia, quasi in imagine proposita habeat. Vestram eo etiam nomine authoritatem amat, ut cum suis destituta sit ornamentis, vestro se splendore tueatur. Nam sive aviti claritudinem generis, seu privatam spectatissimae indolis vestrae virtutem spectet; ea sunt ejusmodi, ut publicâ Provinciae opinione elata nihil omnino aemulis, nihil invidiae debere videantur. Ut proinde non in vos tantum, sed in communem etiam existimationem injurius videar; si hoc publici monimentum amoris, vestrae in Ferdinandi nomen observantiae certam tesseram, à me ultra patiar desiderari. Nempe id FERDINANDUS II. Caesar de vobis, nobisq. meruit, ut humanis subductus oculis, in omnium animis aeternâ memoriâ vivat. Et vos, Comites Illustrissimi, de pietate id meruistis, ut per vos in posteritatis memoriam perennet. Ego verò si quid de vestrâ merui gratiâ, id opto, ut cum his propensi animi mei studijs, meipsum unâ suscipiatis, & vivatis sub FERDINANDI nomine felices.

Addictissimus servus in Christo
Ferdinandus Montegnana.

ORA-

Figure 5-42: Montegnana’s dedication to the first Carniolan vacuumist, Janez Vajkard Auersperg and his brothers to gain their confidence in Montegnana’s printed edition in 1637.

5.4.7 Conclusions

The schools do not merely appear to be an important part of the human being and life. In fact, they define it as deeply as ever, once upon history even more than now, when the world's web is becoming a rival to the teachers of blood and meat. The future vacuum researcher, Janez Vajkard Auersperg, soon left his Ljubljana's school benches. On the one hand, the wider continuation of his studies could be an obstacle to his political journeys to the wider world. On the other hand, Ljubljana did not even have enough higher schools for him.

5.5 The First Vacuum Pumps among Slovenes

5.5.1 Introduction

In the modern world, vacuum is part of our everyday life of food or lighting; therefore, vacuum pumps are also numerous. Of course, this was not the case many centuries ago, since vacuum pumps were the most expensive machines in the European world of the inventions for decades. Three centuries ago, Hauksbee's manufactures began their mass production in London and later Musschenbroek's enterprise in Leiden joined them; soon the prices became more accessible. Where and when did the first vacuum pump run on today's Slovenian territory?

The question provides by no means easy answer. The traveling of books is much easier to follow than the export of machines. Books have always been the high-valued commercial merchandise, so that the officials always took care over their resale. A rare careless person will reject the book, because everyone knows that it can be sold with a profit. But we treat the machines differently: so long as they work, they are used, when we can replace them with more efficient ones, we are happy to discard them. The old machines did not have value on the markets until recently and today we are barely trying to protect the industrial heritage as an important instructive memory. In preserving their industrial heritage, the Croatians are one step further than the Slovenes, since Rijeka with an effective Pro Torpedo association and other neighbors' cities try to transform their former industrial plants into memorials from which new technological solutions could be learned.

The history of technologies is by no means free from problems; however, there are many more collections of old books in the world than museums of once important, but now unmanaged machines. Therefore, it is much easier to find out when a single basic book about vacuum techniques arrived in Ljubljana, rather than guessing when Slovenians first started a vacuum pump on their home soil for their pioneering time. Despite the difficulty of researching, let's try to get that tough nut resolved for our readers!

5.5.2 Guericke's Inventions among Slovenes

The prince from Ljubljana, Janez Vajkard Turjaški (Auersperg) was the main Guericke co-worker and critic. Of course, his money was not lacking, and his elder brother, Volf Engelbert, was the wealthiest guy in city of Ljubljana. The Auersperg Brothers placed in Ljubljana the best private library in those days. In their palace on the premises of the modern NUK, they also had a special room full of strange foreign curiosities, as was usually the case among wealthy educated guys; in the wilderness of later centuries, this pleasant tradition has been lost for good. Naturally, visitors to Ljubljana did not miss the opportunity to watch their famous collection. Thus, we have kept quite a few descriptions of Auersperg treasures. Auersperg's Rubens was particularly honored because he hung at least one of Rubens's art in the palace, and of course, the other Carniolans also kept Rubens's works, among them the later Jožef Kalasanc Erberg in Dol,[465] the grandson of Janez Vajkard Auersperg's customs officer. Some wall and ceiling paintings were made by the renowned artist Almanach from Antwerp in the Auersperg's Palace in Ljubljana around the year of the death of Janez Vajkard Auersperg's brother Volf.[466] Valvasor kept Dürer's "Samson Kills the Lion" of 1496/1497 in a later print, made around 1600.[467]

Janez Auersperg's elder brother Volf bought Rubens's book on architecture published in Antwerp; but it is not entirely clear from the librarian's record whether he owned one or the other Rubens' books published there in 1652; he almost certainly got both. Rubens was also honored at the Academy dei Lincei of Galileo, as his disease was treated by the member of academy Johannes Faber (Fabro).[468] In the halls and fifty-two living rooms of his palace in the middle of Ljubljana, Auersperg exhibited a portrait of emperors Ferdinand III and Leopold I next to the painting of Rubens, the chronicles of

the success of Emperor Charles V and many oriental valuables; he covered the marble floor with Turkish and Persian rugs, and he spread the Dutch Gobelins along the walls. At the front of palace, he arranged a garden with southern fruits like lemon-trees and orange-trees as the climate used to be much milder in those days. In the room of treasures, he had war trophies, paleontological rarities and even a hand of mummy. The inventory of the palace together with forty-eight paintings was compiled in the register of the first Auersperg prince, the vacuum researcher Janez Vajkard, in 1677,[469] and again at the handover among his grandchildren in 1762. The building was especially admired by Emperor Francis Joseph during a visit to Ljubljana in July 1883.[470] Unfortunately, none of the contemporaries of the first prince of Auersperg and his brother mentioned any vacuum pumps in the Auersperg 'princes' palace. Guericke's performance of the device was not only extremely expensive, but it was also characterized by obesity and weight. Such a machine would, of course, catch the eyes of the people of Ljubljana, and so one can find only one reason for the silence of visitors about a possible vacuum in the Auersperg Palace; despite of friendship with Guericke, Janez Vajkard did not bring the vacuum pump to Ljubljana.

Janez Vajkard Valvasor learned his skills as a young nobleman during his visits to Wolf Engelbert Auersperg's fests. When he finished the main part of his world-wide tours, he arranged the premises and library in Bogenšperk according to the Auersperg's Ljubljana model. Was Guericke's, Boyle's, or even Huygens' vacuum pump among his castle treasures? Hardly. In any case, it is not among Valvasor's legacy, recorded in his last home in Krško.

Like Valvasor, Janez Danijel baron Erberg learned a lot in the palace of Wolf Engelbert Auersperg, including his first reflections on science. Erberg's great grandchild, Jožef Kalasanc baron Erberg, in many ways repeated the political path of the first prince Janez Vajkard Auersperg, as Jožef Kalasanc was also the educator of pretender to the throne in Vienna. Later, he suddenly returned to Carniola. In today's beautifully preserved pavilions in Dol, Jožef Kalasanc decorated the library and the first museum in Carniola. He adorned his library with an educative note above the entrance and saved a lot of the vacuum-related book on it - did he store a vacuum pump in the neighboring museum pavilion? His son-in-law sold most of Erberg's books to Rudolfinum which is today's National Museum in Ljubljana. The peculiarities of the museum from the neighboring pavilion were scattered by all sorts of the winds. While we are maintaining the Erberg's library catalog, the list of objects from the former Erberg's Museum in Dol is not available.

5.5.2.1 The Vacuum Fun in Carniola

The prince Auersperg had enough money in his treasures; maybe he got Guericke's pump, which was the biggest and most expensive scientific instrument of the time? Perhaps at least some small vacuum preparations have been brought to his Ljubljana mansion? He certainly did not buy the first pump from 1648 or that from 1650, which was used by Schott, but he could supply the pump from 1662. Several pumps were only available after the fall of Auersperg's Viennese policy. The humiliated Auersperg prince with his wife and his seven children went to Wels, and then to his Ljubljana home in Carniola. During his frequent hunts he cooled the anger over the fading of his happiness and entertained himself with scientific studies. On July 7, 1669, he bought from the Prince Janez Anton Eggenberg the Inner Carniola manors of Snežnik and Lož and took over the Postojna manor. In 1623 Cluverius described the Postojna cave as a "big cave with the effervescent river in the hollow hill by Ljubljana". This and his other works were known to Carniolans, as they were offered as many as five Cluverius' books in Ljubljana in 1678.[471] The humanist Cluverius has established himself with geographical research of antiquity and the Middle East. After his long journeys in Germany, Italy, France and England, he befriended Thomas Bartolin and lectured at Leyden University, where Guericke studied immediately after Cluverius' death.

At that time, the Postojna cave had already been visited and the folks studied underwater flow of Pivka river "even a mile far". Therefore, the curious gentleman Auersperg of the "benevolent

[469] Žargi, 2002, 282; Radics, 1885, 28.
[470] Radics, 1885, 227, 28, 29; Radics, 1878, 54.
[471] Mayr, 1678, 71–72.

memory", as a new owner of Postojna, undertook his own research. In 1673, he lowered one of his paws on the ropes to the water in the river under the thick natural bridge in the Postojna Cave. The farmer was an apprentice fisherman equipped with fishing nets, since the economical Auersperg was particularly attracted by speculations about the underground animals that he was reading in Agricola's works. A man used the single-rope technique for his descent. He skated on a rock during a slow downhill and finally came to the water. His aides enjoyed some funny chatting and did not do too much to pull up their researcher quickly or safely. They were very pleased when he finally climbed back to the bridge and brought a pike, a carp and a clone in his net. The fish were not specially reared, but more like skinny. Auersperg was nevertheless satisfied and wanted to repeat his observations during the next day. He again offered the man a crown for his effort. However, the stubborn farmer did not want to go to the deepness again, even if Auersperg wished to give him the entire Postojna manor. He refused any further cooperation: "I will not tell about anything what I have seen and heard; but I will even not tell why I do not want to go down anymore!" He was so convincing that nobody knew how to help the prince, not with the word, nor with a sword. Further research had to be abandoned, since new volunteers wouldn’t do it either, of course. Thus, one of the first planned Carniolan modern experiments ended quite laughable.

In 1679, a year and a half after Auersperg's death, Valvasor found the elderly cave fisherman and tried to find out the details of the famous underground experiment from him.[472] Unfortunately, this man again did not want to say anything useful. From his behavior, Valvasor assumed that the scarecrow was displayed in the cave. Valvasor was assisted by the Provincial Governor, Prince Janez Sigfrid Eggenberg, who in the meantime took over the Postojna manor. Valvasor worked closely with him and devoted to him a map of Croatia at the beginning of the 12th book of his Glory (Slava). At that time the owner of the nearby castle Jama (Luege) near Postojna was the Count Janez Filip Cobenzl (Kobencl), the grandson of the brother of the mathematician-rector the Jesuit Janez Rafael Cobenzl.

As Cobenzl (Kobencl), Auersperg also became a fan of the local Jesuits. In 1674, together with his relatives and sons, Auersperg attended a dinner in the suburban Jesuit house in Ljubljana. He paid the costs of a whole banquet; when they were extensively served foods and drinks, the servants took the tables away and provided some entertainments, while the prince gave the great presents to everybody. The Jesuits of Ljubljana were also supported by the descendants of the princes. On the day of Jesus' circumcision in the winter of 1st January 1682, the son of the deceased first prince, along with the other highest nobles, attended a feast at the Jesuits in Ljubljana and vigorously supported the beginnings of scientific and higher education in Ljubljana.

After the death of his unmarried brother Volk Engelbert Auersperg, the prince inherited his estate. A week before his death, the prince brought together the manors of Poljane, Kočevje, Višnja Gora, Belaj, Žužemberk and the prince's manor into the trust (fidejkomis), which only the firstborn of the family could inherit. His descendants thus became the largest landowners of Carniola, but the real center of their wealth was in the Bohemian Sudeten Lands.

The Prince of Auersperg introduced the enthusiastic Carniolans with the beginnings of a vacuum technique in the empire and told them about some other jolly gossips of court intrigues. During the hunt he told his helpers, his subjects and the nobleman about the unusual properties of the emptiness. His stories fell to the fertile ground, as well-known among his listeners were Lienhardt Panian, Anne Panian and Jurco Panian from the Tanča Gora and Dragovanje Village of Bela Krajina in southern Carniola. Their descendants are today among the leading Slovenian vacuum researchers.

For his hunting and local politics, Auersperg needed loyal Carniolan nobles. The service of the prince was best used by the Verderber family employed as the customs officers at the Prince’s Leiden Tree (Knežja Lipa) in the Kočevje lordship. After that manor was taken over by Volk Engelbert Auersperg, the Verderber family got their noble ranks. Since name “von Verd-erber” sounded a bit embarrassed, they renamed themselves into "von Erber" and finally to von Erberg. With a welcome Auersperg's support they

[472] Reisp, 1983, 144.

soon grew up too wealthy for Kočevje (Gottschee) manor and gradually moved their business to Ljubljana areas. The Kočevje native Janez Danijel, later baron Erberg, grandfather of Avguštin Hallerstein, was one of the main prince's helpers. The Auersperg prince told Erberg and other associates in course of hunting games and a pleasant glass of local wine about the wide world and about fashionable vacuum experiments.

The Erbergs imitated their benefactors in the purchase of scientific literature. On January 2, 1680 Anton's uncle, Franc Jakob Erberg, bought and rebuilt the house on today's Old square number 9 in Ljubljana and arranged a rich library in it. Since all his children died, the house and the library with many books about the vacuum were inherited by his half-brother Janez Danijel Erberg,[473] who continued to enjoy the support of the Auersperg princes in Ljubljana. Prince Janez (John) Weikard was succeeded by his oldest son who, shortly after his father's death, married a countess from the mighty Herberstein family in 1678. In the meantime, Erberg's library grew and soon almost surpassed its model in the nearby princess castle (Figure 5-43). Karel Dežman bought at least part of the Erberg library for the National Museum in Ljubljana of today, but the Auersperg's Book Treasures were mostly sold to the American libraries in 1982. The auction in London took part without much of the Carniolans, who, of course, already had too much vacuum in their pockets.

Figure 5-43: One of the last photographs of the Prince's castle in Ljubljana, recorded after the earthquake in 1895

[473] SBL, 1: 162.

In 1791, the Auersperg princes received a ducal title and with it they achieved the privilege to mint their own money in the Duchy of Kočevje inside the duchy of Carniola. Auersperg's customs officer Erberg have also progressed and successfully jumped into the high society circles. After the first Prince of Auersperg educated the Crown Prince Ferdinand IV, the descendant of his former tax collectors, Baron Jožef Kalasanc Erberg became the educator of the Crown Prince Ferdinand I in the spring of 1809. Unfortunately, Ferdinand I was not overly glittering on the Habsburg sky while ruling from his imperial throne.

5.5.2.2 Boyle and Hooke: Exploring Vacuum in England

In addition to other Europeans, the English researchers in the middle of the 17th century also discussed their empty spaces. The most famous English thinker of experimental science, Bacon, wrote about the vacuum. Unfortunately, King Charles II did not support the research of vacuum as the patron of the Royal Society (RS) organized in November 1660 at the Gresham College and officially established two years later. As early as on 1 February 1662, the king ridiculed "weighing the air of the Greshams". "Weighing" or "blending," that is, determining the density of the air which to all uninitiated must have seemed a serious waste of time. The density of the air was already measured by Galileo in 1613, however he got about twice as high result than a modern one.[474] Later they measured more precisely, since they were able to determine the difference in weight up to 6.5 g in the 17th century.[475]

On 6 May 1653, a physician from Halifax and a later Fellow of the Royal Society (FRS) Power performed measurements like Pascal's on a hill Beacon by Halifax.[476] The experiments were later repeated by Ball, Towneley and Boyle at the top of the church in Westminster. In January 1658, Boyle read about Guericke's experiments in Schott's book from 1657, and he repeatedly wrote to Schott.[477]

Robert Boyle was born in Ireland as the seventh son of Count Richard. He studied at home and traveled throughout Europe until 1645. During his trip to Geneva, he was supposed to "turn to experimental philosophy". From 1654 he lived in Oxford, where the open coffee shop Tillyard's hosted the advocates of "experimental philosophy" in 1656. In July 1660, Oldenburg began to work closely with Boyle and his nephew. In 1660, Boyle moved to his sister's household in London, but he still frequently stayed for longer periods in his house at Oxford. During the plague in 1664, he led the RS in Oxford. He helped to establish RS, and edited the Phil. Trans. In April 1668, he finally moved to London and actively participated in the RS. In 1680 he was elected president of the RS, but he did not accept the position. In addition to chemistry and physics, he also studied and wrote about theology.

Robert Boyle (*1627; † 1691)[478]

As Pascal a decade before him, Boyle had also developed his vacuum experiments at Oxford within a broader research of the properties of liquids. Pascal's barometric experiment of Puy-de-Dôme was repeated in Boyle's laboratory. As Guericke's competitor, Boyle developed three vacuum pumps. The first two of them were assembled by Hooke. The London-based device manufacturer, Greatorex, was trying to improve Guericke's pump. However, according to Hooke, his device was too large for useful handlings. At the end of 1658, Boyle agreed to develop a pump with Greatorex and Hooke, who had been his assistant for a year. Hooke has compiled his model called "pneumatic machine or air pump".[479]

Robert Hooke was born in the priest's family on the island of Wight. He studied at Westminster and at the Oxford University, where he and his relative Dr. Christopher Wren were under fatherly protection of John Wilkins, who was the first secretary of the RS along with Oldenburg. In 1655, Hooke moved to Oxford, where Wilkins later recommended him for the post of assistant to Boyle. From 12 November 1662 Hooke was an administrator of experiments with the RS and thus the first professional scientist in Britain. In 1664, he became a professor of geometry at Gresham University, where he lived until his death. On 11 January 1665, he was promoted to a life-long guardian of experiments in the RS, whereby, after Oldenburg's death, he was also secretary and editor of Phil. Trans. between 1677 and 1683. Hooke contributed to the development of many sciences: physics, horology, physiology, geology, astronomy, meteorology and architecture.

Robert Hook (*1635; † 1703)

In 1660, Boyle listed the experiments performed in the previous two years with the first Hooke's

[478] Bogoljubov, 1984, 47; Schaffer, 1993, 236, 259, 289, 297, 314.

[479] Nichols, 1999, 22, illustration after page 86.

piston pump[480]. Among the main critics of Boyle's results were Linus and later Newton's Teacher Henry More (1614-1687), a Platonist from Cambridge. More, like Hobbes, rejected the essence of the experimental program of the RS. The members of RS Wallis, Flamsteed and Hooke defended Boyle from Before More's criticism. Zucchi thought that the vacuum above the mercury column was still full of mercury (vapours), which was accepted by Casati, but not by Gassendi and Valeriano Magni.[481] The name mercury for quicksilver was hilariously linked with the name of the Roman god, who was supposed to be the protector of the thieves, and therefore smuggled over mercury in the form of invisible vapour, at least the critics of vacuum thought so. The name barometer was coined by the French statistician, Varignon.[482]

In the end of the year 1660 and on 30th May 1667, Boyle showed the operation of his pump to the beautiful opponent of animal testing Margaret Lucas Cavendish, Duchess of Newcastle-upon-Tyne (1623-1673) and the Tuscan archduke on their visit to the Gresham College. Immediately after the new year 1661, the Society, which changed its name a year and a half later in the RS, asked Boyle to bring a pneumatic machine and show the fellows his experiments. Hooke and Boyle simplified pumping by using the iron rack and pinion device to push the piston up and down. They did not like the large amount of water which Guericke needed to seal his device. They used lubricating taps machines and valves, which had to be manually opened and closed. The wooden piston was lifted and lowered through the bronze cylinder. To ensure good sealing, a "piece of tanned show-leather" was placed between the piston and the inside of cylinder. Their machine ointment was a mixture of olive oil and other vegetable juices boiled together with PbO. They added a little kitchen salad oil to lubricate a cylinder, valve and a round glass vacuum receiver.[483]

On 12 November 1662, Hooke was nominated as the custodian of experiments in the RS. With this new job, he stopped being Boyle's assistant; but they corresponded until Boyle's death. On 16 June 1663, Hooke described his pump in front of the RS.[484]

On 15 February 1665, Hooke and Boyle made an experiment with a vacuum pump in front of the RS. Boyle rejected Cartesian physics, much like Newton did later. Boyle tried to rarefy the content of his vacuum receiver so much as to leave only the smaller substances thinner than air. Unlike of Torricelli or Guericke, Boyle did not try to pump out his receiver to get a "perfect vacuum," but he rather studied the properties of diluted air.

Like Noël, Boyle also saw several species of "matters" in the air, which proved to be true a century later in the experiments of Scheel, Priestley, Cavendish and Lavoisier. However, Boyle misrepresented the gas mixture as inhomogeneous, contrary to the later Dalton's law.[485]

In January 1671, Hooke reported to the RS about his new gigantic vacuum pump connected to the pump. He could sit inside it, as Hooke wanted to investigate the effect of reduced pressure on the human body. Hooke was small and slightly humpy; so, he easily dragged himself into a bowl where the place would be too tight for other people. His hunchback was mocked many times, as Newton ridiculed him with a funny statement that he saw further when standing on the shoulders of the giants.

On 23. 2. 1671, Hooke reported to the RS that he sat for a quarter of an hour in an emptied container and did not feel any special problems. Members of the RS commissioned him to repeat experiments with animals and with a burning candle. He climbed into the container at a pressure of 0.9 bar, but did not feel any problems, except for the pain in his ears. On May 5, 1671, he exhausted the air with bellows and measured the pressure with the gauge. The candle was extinguished much earlier before he felt the inconvenience in his ears. His heart rate did not increase during the experiment.[486]

Papin helped Boyle to assemble a third pump between 1675 and 1680. Hooke's method was improved by substituting the vacuum with "artificial air", CO_2, obtained by soaking coral in the acid. The pump with two cylinders reached 0.01 bar. Two hundred years later Wilde catalogued Boyle's book (1682) with a description of the pump in the library of Ljubljana Lyceum; today it is found in the NUK bind to six books of other authors.

5.5.2.3 Huygens' Vacuum in the Netherlands and in Paris

The vacuum pump and manometer capacity has undergone numerous improvements in valve, connector and trap in vacuum systems over the next centuries, which have enabled lower pressures. These tiny improvements, and mostly the precise cleaning of surfaces, proved to be important in the experiments of Christiaan Huygens, the second son of Descartes' friend the Dutch diplomat and poet Constantijn Huygens.

During the spring 1661, Huygens visited Boyle in London.[487] After seeing Boyle's devices, he built his own pump in November in The Hague. He exceeded his role models because "the bladder remained empty all night," meaning about eight hours. Huygens' pump was better than Boyle and Hooke's use of a wooden piston.

In the same year in The Hague, Huygens observed anomalous suspension in experiments with "vacuum in vacuum" (Figure 5-44). He purified the cleaned glass tube with water, closed it, turned it around and connected it to the water tank. Due to the resulting vacuum, the water in the tube was higher than the level of the collector. He placed it all under the bell-shaped container connected to the pump. When the air was exhausted, he expected to align the water levels in the pipe and the reservoir. But often the water level in the tube did not drop until he shook slightly the device. Boyle, who was dealing with similar problems on the other side of the Channel, initially did not believe Huygens's assumptions; Boyle attributed the result of the experiment to impurities. He and Towneley could not repeat Huygens's experiments. After two years of precise cleaning of their device, Boyle and Hooke finally got Huygens' results with water and mercury. In January 1665 Huygens announced his discovery to Kinner from Prague, who reported the news to Schott. Unfortunately, even the exact Germans and Bohemians did not know how to repeat Huygens' experiments. Huygens did not immediately publish his results, which could bring him a lot of inconvenience today. It was not until July 1672 that his experiment was described in a Parisian magazine of scholars. Two years later, Huygens' former assistant Papin reported on the success, attributing the anomalous suspension to the bubble of air in the liquid.[488]

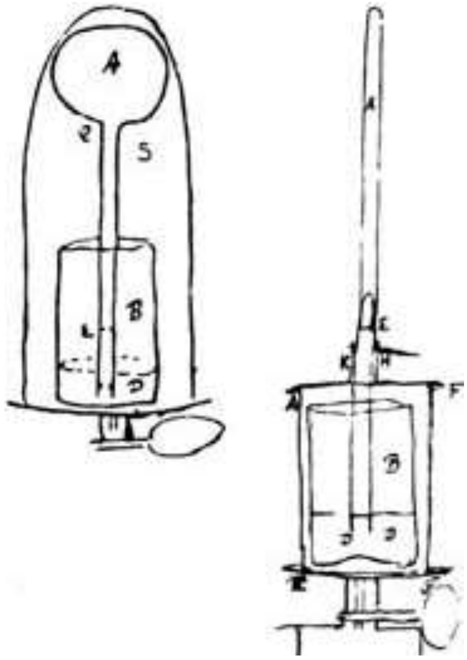

Figure 5-44: In 1660 and in 1673, Huygens' sketch of the experiment with a "vacuum in vacuum" helped to understand the need for precise cleaning of surfaces in vacuum technology

In the spring of 1672, Newton and Hooke quarreled about their theory of colors. Huygens' experiment certainly promised some less severe blood. The RS Secretary, Oldenburg, provided a translation of the Huygens discussion for the August issue of the Philosophical Transactions, since most members of the RS were unable to read the French notes fluently. During the holidays, the members of the RS met only informally, so Huygens' ideas were discussed by the RS only on October 30, 1672. The special interest was shown by Hooke, Wallis, and

[487] Sparnaay, 1992, 25.

[488] Frankfourt, 1976, 158; Shapin, Schaffer, 1993, 244, 271, 273, 277.

president of the RS Brouncker. They published a notable paper about Wallis' letters mailed to Oldenburg.[489]

In July 1672 Newton and after him Huygens attributed the phenomenon to adhesion between two solids or between solid and liquid. While Huygens believed that adhesion was caused by particles of the ether, Newton and the Dutchman P. Musschenbroek attributed the cause to the attractive forces between molecules and not to the force of gravity. Wallis rejected Huygens' Cartesian fine matter; the result of the experiment was explained by the "lack of elasticity" of water or mercury.

On 6. 11. 1672 in front of the RS Hooke read the paper about Huygens' experiment, which was not published. Two weeks later, Hooke carried out additional experiments in which the water was 12 inches above the equilibrium plane before it began to fall. "Huygens effect" was explained by Huygens' Parisian confidant, the poet-critic Jean Chapelain (1595-1674), with the assumption of the pyramidically shaped atoms that supposedly take the leading role in water under exhausted air. Of course, Huygens refused that idea too. He himself saw in the phenomenon the pressure of a fine substance, like Hooke. Later, Laplace attempted to explain the experiment with capillarity. In the 19th century, the phenomena interested the Belgian Jean-Jacques-Daniel Dony (abbé Dony, 1759 Liège-1819 the Englishman Charles Frederick Partington (Wartington, † 1857), and after them the German Helmholtz. In the 20th century, the research was continued by Huygens' fellow Dutchmen Kamerlingh-Onnes, his student Willem Hendrik Keesom (1876 Texel-1956 Leiden) and Casimir at Philips Research Laboratories in 1948 (Figure 5-45).[490] The electromagnetic causes of the Casimir effect have shown that Newton may have been amongst the closest to the truth.

In 1662, Huygens assembled another pump, which became a model for many later performances. Position of the components of the first pump were turned upside down on that occasion. By adding a mixture of oil and water to the piston, the surface between the piston and the roller was better protected against moisture, and at the same time retained enough moisture for the leathered ring around the cylinder. While he descended the cylinder, the valve opened and let some liquid in. He bound his vacuum container and the pump in the metal plate. Since he did not find enough experienced glassblowers among the Dutch experts, Huygens used a pharmacy dish for a vacuum container.

Figure 5-45: Hendrik Brugt Gerard Casimir (*1909; † 2000)[491]

Huygens settled down in Paris in 1663 to develop a new center for vacuum research. He presented the air pump to the Montmor's Parisian Group. In 1664, that group became the foundation of the Académie Royale des Sciences (AR) with Huygens as its leading member, though without the important associate Petit. Huygens stayed in Paris for two decades with interruptions due to his return to the Netherlands in June 1665 and the illnesses between 1670 and 1671 and between 1676 and 1678. In a later version of the pump presented in 1668 before the AR, Huygens replaced the metal plate with two inches thick wood connected to the iron plate that fixed the pump. He used bronze emptied receivers with wide apertures, which enabled a variety of experiments. The problem of sealings between the container and the base plate was solved with a lot of soft yellow mixture of wax and turpentine.

[489] Wallis, *Phil.Trans.* 24. 2. 1672/3.
[490] Sparnaay, 1992, 47–50.
[491] Casimir (anonymous notice), Europhysics News, July-August 2000, 30.

The same cement was used by Boyle, who remained in genuine relations with Huygens. Huygens confirmed the validity of Boyle's law and derived a barometric equation that heightened his interest in logarithms.[492] The same equation was used by Newton in his Principles.

The work of the first vacuum researchers was often dangerous. On 14. 4. 1668, during the fourth Huygens pumping of an octagonal vessel in front of the members of the AR, there was an explosion; the particles of the device were flying a meter far. Luckily no one was seriously injured, and more cautious academics later watched Huygens' experiments from an academic distance. In the next week, Huygens gathered somewhat scared members of the AR and showed them an experiment with a clock. Its ringing was almost no longer heard from the exhausted container in which the clock was immersed. As the first, Kircher proposed a similar experiment with the magnetic deviation of ringing bells in a vacuum. Guericke made that experiment which again proved excellent collaborations among the Catholics and Protestants of those times.

In 1673, Huygens published a plan for a pneumatic lift, where the blast explosion lowered the pressure in the vessel. The air pressure pushed the piston into the bowl and raised the weight. With his elevator, Papin raised four or even five people with the excited exclamations of AR members and of the mighty minister Jean-Baptiste Colbert himself. Unfortunately, the procedure was not repeatable.[493]

Ten years later, the Protestant Huygens returned to the Netherlands before the revocation of the Edict of Nantes could damage his faith in October 1685. His work was subsequently continued by one of his executives, de Volder, in collaboration with the workshop of Johannes Joosten van Musschenbroek, the father of later famous physicist Pieter Musschenbroek.

5.5.2.4 Papin's Pumps

Like Huygens, Papin was also a Protestant. The Huguenot Papin was born to the wealthy parents in Coudraies near Blois, 150 km southwest of Paris. In 1669 he finished the University of Angers. Two years later, he went to Paris, where he learned mechanical skills at the Antoine Gaudron’s (1640-1714) watchmakers manufacture. Papin collaborated with Huygens and became his assistant in 1672/73. Huygens's advice opened new horizons to him at meetings with Leibniz. Papin invented his handy three-way switch to become a member of the AR and RS.

Just like later Huygens had to abandon Paris when the Protestants lost their space in France a decade before the abolition of the Nantes Edict in 1685, Papin was also forced to find his new fatherland. Papin became Boyle’s helper in London, in 1679 Hooke’s assistant in managing the correspondence of the RS, and finally the custodian of the experiments in the RS. Between 1688 and 1695, he was a professor of mathematics at the University of Marburg in the service of Count Karl of Hessen. Unfortunately, the count wasted too much money for his war against the French to pay the Papin's inventions well enough. That is why Papin traveled through Italy and Germany for several years. Between 1692 and 1700 he argued with Leibniz about the measure of motion. For the proposals of the quarreling parties, they later coined the terms impetus, momentum or the quantity of motion ($m \cdot v$) and the "living force" of Papin’s times, later referred to as the kinetic energy ($m \cdot v^2$). Papin was sorely defending his Cartesian position of the preservation of $m \cdot v$.

In 1707 Papin returned to England, but both his patrons, Boyle and Hooke, had already died. Therefore, he could not get a job at Newton's RS, where he cooked for King Charles II three decades earlier in an economic pressure cooker with Papin’s design of steam-release safety valve. Finally, he was struggling for his piece of bread when he died in a significant shortage in London with almost nothing to boil in his pressure cooker.[494]

In May 1674 the Parisian academician Mariotte estimated Papin's pumps as twice cheaper, safer and more useful than Huygens’ device. They were sold for four English Guineas, as we read in the report of Huygens' mechanics the Englishman Jean’s son Louis Hubin (* 1628; † 1703) who

[492] Shapin, Schaffer, 1993, 267; Frankfourt, 1976, 101–102.

served as the enameller (émailleur du roi) to the French king in rue St Martin of Paris in 1687.[495]
On 14 December 1687, Papin presented his vacuum device for circulating water by diluting the air in front of the RS, immediately after the election of the new FRS, the Carniolan Valvasor. At that time, they read the first part of Valvasor's letter about the flow of water through the karst underground below the Lake Cerknica, which was based on the older theory of the Jesuit Kircher. First, Papin showed his vacuum experiments, then Newton's friend Halley illustrated the filling and emptying of the Cerknica lake according to Valvasor's description with the help of three connected containers placed at different heights. Valvasor certainly personally met important vacuum researchers when he traveled through Germany, France and England between 1658 and 1672. In 1667 he was in Paris, later in Toulon and in Lyon again in 1670. Thus, Carniolans were again somewhat nearer the pioneering research of the vacuum.

Except for Guericke, all pioneers of the vacuum exploration started their research very young: Torricelli was thirty-six years old, Pascal twenty-four, Carniolan Auersperg 39, Boyle 32 and Huygens 31. Their assistants, Viviani, Hooke, Papin and Hauksbee, of course, were even younger. The first barometer and air pressure experiments were carried out in the Catholic circles of Northern Italy and France, and the first vacuum pumps were developed by Protestants in Germany, England, in the Netherlands and France. For some reasons, the early pumping which enabled the changing of the experimental tools inside of vacuum receiver seemed to be the affair of Protestants, while the Catholics preferred the better vacuum of their early barometric tubes. The deniers of vacuum grew on both sides like the protestant Leibniz or the Catholic Jesuits and Descartes. Most of the young vacuum technology pioneers have traveled a lot at least during their studies, while Huygens and Papin have journeyed even as the established researchers. In this way, the details of the inventions spread relatively quickly through demonstration and personal contacts, especially in the scientific societies in Florence, London and Paris. These academies have played the role of modern vacuum societies, although they were, of course, intended for all branches of knowledge. For most early researchers, the investigation of vacuum was only part of their wider research projects focused on the properties of liquids, especially in Pascal and Boyle's networks. Hooke and, above all, Huygens were experts for almost all physics. Despite the bloody religious wars of the time, religion was not an obstacle to the spread of discoveries. Thus, the Protestant Boyle learned about Guericke's experiments by reading the book of Jesuit Schott. More bitter disputes involved the British vacuum researchers due to political tension during the Restoration.

With his description of the vacuum, Boyle came across a fierce rival, his four decades older philosopher Hobbes. The dispute was politically colored; Boyle's elder brother, Broghill, was a member of the weak government of the Protectorate after Cromwell's death until May 1659 and an adversary of the Presbyterians. The monarchist Hobbes opposed the authority of both Catholic and Anglican churches; of course, he cordially greeted the Restauration in May 1660. He was F. Bacon's secretary and the friend of Harvey. In Parisian exile Hobbes taught mathematics to the King Charles II. In 1662, he devoted himself to "Physical Problems"; but later received the royal salary, though quite irregular. He rejected the idea of Boyle's RS about the basic role of experiments; he had such a position to defend the philosophical pursuits against "craft" work, even though Hobbes admired Galileo. The idea of a vacuum seemed overwhelming even in political terms. Although Hobbes' works were never printed in *Phil.Trans.* of the RS, his criticism strongly influenced experiments and even the changing of Boyle's vacuum pump performance. The Boyle's group of moderate puritans in the RS supported the parliament against the king in fear of absolute monarchy. Later, Boyle's group was politically successful, as RS had received the right to print, while in 1668 Hobbes was banned from publishing political and religious works in England and forced to issue them in Amsterdam. In 1674, due to political controversy, Boyle was particularly hostile to Hobbes' collected works which appeared in 1668. Hobbes had an attractive force at contact between smooth marble plates for the main evidence against Boyle's description of the vacuum. The phenomenon was explained only by Leibniz in February 1672, by Huygens at AR in June 1672, by Newton in a letter to Boyle

[495] Shapin, Schaffer, 1993, 273.

on February 28, 1679,[496] by Josef Stefan, and Casimir.

Vacuum pumps were the most expensive scientific tools of the time. According to preserved paintings, Boyle's pumps were about 0.5 m high, that is, much smaller than Guericke's giant, located on two floors of the house. Even the gigantic barometers with water or wine were not cheap. Much experience in blowing glass was needed to make such devices. Thus, Mersenne could not design the Torricellian experiment in Paris, where he had no capable craftsmen at hand. Pascal was more successful, as he was helped by the famous glassblowers from Rouen. From 1647 to 1670, a total of fifteen pumps were built in Magdeburg, Oxford, London, Paris and the Netherlands:[497]

- The first Guericke pump in Magdeburg in 1648. Two years later, he created a pump, in which he evacuated hemispheres for the famous Magdeburg experiment in Regensburg in 1654 and sold it to Schönborn.

- Greatorex's improvements to Guericke's pump.

- One or more pumps at the Boyle's house in Oxford. The first of them was made at the beginning of 1659 in London and they transferred it to Oxford in March. In December 1661, a new pump was planned in Oxford.

- One or more air pumps were in the Gresham College in London after Boyle transferred them from Oxford in the summer of 1660. With it, Hooke experimented from 1661 to 1663, and the operator Mayow showed visitors the operation of pumps in the autumn in 1667.

- Pump in Halifax in 1661.

- Huygens took the pump to the Netherlands in the autumn of 1661.

- By March 1663, Huygens assembled and later operated a pump for the Montmor's group. The group with Pascal's friends Petit, Roberval (until 1658) and others operated between December 1657 and May 1664 in Paris.

- In the mid-1660s they had a pump in Cambridge.

- Huygens brought the pump, built in winter 1667/68, into the rooms of AR between March and May 1668.

- Another Hooke's pump with a mercury gauge made in 1667, which Boyle described two years later as "An experiment that tests the motion and sensitivity of Cartesian fine matter called ether."

- The third Boyle's pump was compiled by Papin.

- Senguerd constructed a pump with a single almost horizontal piston, which he mentioned in his "Philosophy of Nature" in 1681 and described it in detail in the second edition four years later. According to Guericke's example, he used an oblique position of cylinders and sealed with water. His toothed rails, the front wheel and the cross-spindle were summarized = by Hooke, two pistons on one rod designed after Papin, and the installation of the elements reported by Boyle.[498] According to Senguerd's plans in Leyden, Johannes Joosten van Musschenbroek made a convenient pump. Johannes Joosten's son, Pieter van Musschenbroek, took over Senguerd's Chair of Physics at the University of Leiden and contributed to the sale of the pump throughout Europe. Musschenbroek's pumps from the beginning of the 18th century used to be among the oldest preserved[499] since most of the elderly tools were destroyed by the teeth of time.

- Hauksbee's double-cylinder pump, manufactured according to Boyle and Huygens' plans of 1675, was on sale between 1703 and 1709. Individual products are still on display today.

5.5.2.5 Hauksbee's Vacuum Pumps with Ljubljana Franciscans

The vacuum pump caused first-class philosophical disputes between Aristotle's or Descartes's followers and their antagonists, the Galilean admirers of modern new science. The main propagandist announcer of novelties was Francis Bacon, who, like Janez Vajkard

[496] Shapin, Schaffer, 1993, 93, 114, 134–139, 150, 189–203, 225, 280–281, 290–292.
[497] Hellyer, 1998, 295.
[498] Schneider, 1986, 399.
[499] Hellyer, 1998, 295, 335.

Auersperg half of a century later, ended political work in disgrace in 1621 and devoted himself to science. Janez Vajkard Auersperg felt the resemblance of his own and Bacon's fate, and he therefore paid for the first German translation of Bacon's work. At the same time, he decorated the Ljubljana palace with a picture of the fall of Helios' son Phaeton, whose prided but incompetent drive of solar chariot Zeus punished with a deadly strike.

In the meantime, the vacuum pump in the hands of the draper's son Hauksbee the elder (* 1660) became part of the industrial offer after the initial Boyle's support. His nephew Francis Hauksbee (* 1687) already advertised his vacuum pumps as a member of a powerful Drapers' Company of the City of London. After Hooke's death, the experiments in the RS were being prepared by the self-taught Hauksbee the elder (* 1660). He used to be Boyle's assistant, but he was not employed by the RS as Hooke used to be. On 15 December 1703, at the first session of the RS, under the direction of new President Newton, Hauksbee described an improved double-barrelled air pump with two pistons, which was much easier to use. Boyle's pump enabled Hauksbee's observations of the speed of moving bodies in a vacuum. The next year, Hauksbee emptied the container with a volume of 0.7 l to a pressure of 0.0025 bar within two minutes.

The erudite of Ljubljana closely followed the western novelties. Guérinois' work, read by the Franciscans in Ljubljana, became more involved in Gassendi's atomism and experiments with the (Boyle's) pneumatic vacuum pump. Jacques-Casimir Guérinois (1640 Laval in western France-1703) was a Dominican monk who served as the professor of theology in the University of Bordeaux. His books in Ljubljana Franciscan library proved again that the monks might have some political quarrels among their orders, but they certainly loved to read useful valuable books of their alleged opponents without any real limits.

5.5.2.6 Getters

The term "getter" is derived from the English verb "to get". The getter reacts well with gases and thus removes them from space. The getters appeared very early, so pumping was soon no longer the only way to get a vacuum. As early as in 1674 and 1684, Boyle investigated the porosity of the substance and the occlusion of gases. The phosphoric anhydride was used initially to remove traces of water vapor in a vacuum. In 1772 Fontana discovered the adsorption of gases in hot wood charcoal. He was a priest, a professor of logic and physics in Pisa, and then in Florence, where he was also a physicist at the court of the Archduke Leopold I. The insulation of his pumps prevented any contact with the outside air while the ember of burned charcoal was dying. With this, the adsorption effect of charcoal was saved for the air in the recipient. Landriani described Fontana's achievement in a letter mailed to the Englishman Priestley, who successfully repeated the experiments in 1775. The discovery was, in one way or another, used by Scheele (1773) and B. Higgins (1776).

The invention of Fontana was described by the Dutchman Ingenhousz upon his return from Vienna to England in 1782. Ingenhousz assembled a device with a cover made of copper and of brass, but unlike Fontana, he considered that it was not possible to get such a good vacuum with gettering alone as with pumping. The Croat Domin agreed with Ingenhousz and announced that the adsorption could be used elsewhere.[500] The Frenchman Regnault of Collège de France improved the vacuum by replenishing the container with water vapor before pumping; then it was extracted with H_2SO_4, stored in a smaller container which Regnault finally broke within the emptied receiver. The procedure was repeated several times. A similar method with CO_2, oxygen and other gases was later developed by others. In 1852, Andrews followed Davy's = advice and twice filled his vacuum receiver with CO_2 and emptied it. After that, he fixed the rest of his gas with potassium carbonate.

Andrews' method was taken over by Gassiot who used potassium carbonate to remove enough gas from his Geissler's cathode ray tube to prevent discharge. The exploration of adsorption in charcoal was continued by Dewar and Tait in 1874. The vacuum was obtained only by adsorption, completely without pumping.[501] Dewar increased the adsorption power of charcoal with cooling in the liquid air. The

[501] Andrews, 1889, 224–227; Dewar, 1927, 1116, 121, 127, 892, 1014, 1118, 121, 127, 894, 1120, 1244.

obtained pressure was estimated at $3.8\cdot10^{-3}$ mbar (1/350 torr). Finkener filled the oxygen tank and exhausted it. By heating the copper to the red grill, he then bonded the remaining oxygen to the copper oxide and got a pressure of 0.033 mbar.[502]

5.5.2.7 Early Vacuum Experiments of Italian Jesuits

The getters and barometers were essentially the Florentine inventions. Galilean physics and vacuum experiments of Florentine academicians were much more slowly accepted at Jesuit schools than Bošković's physics a hundred years later. The Jesuits at least at first initially resisted the existence of a vacuum as a logically impossible and equal to zero. Vacuum experiments have been interpreted by the Jesuits of Linus' networks. The drawings in Jesuit manuscripts are the only relevant data on glass devices for vacuum experiments used at Italy and at the end of 17th and early 18th centuries. The vacuum pumps composed in London, Oxford, Paris and the Netherlands were different from school sketches of Italian professors, which show some specific features of Jesuit vacuum research (Table 5-2).

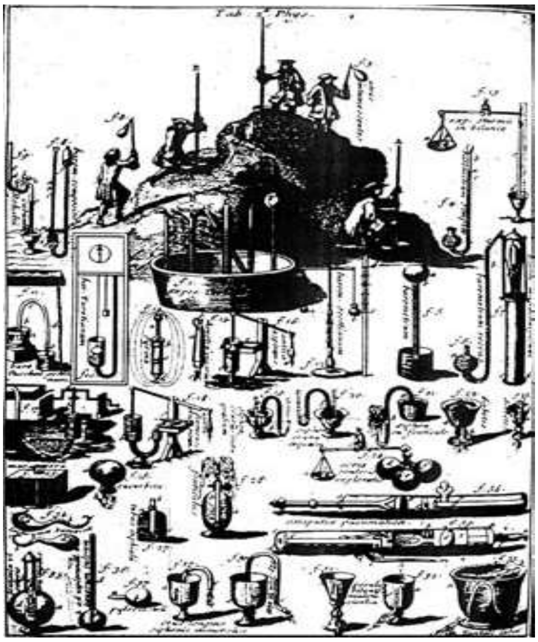

Figure 5-46: Measuring the height of the hill with the barometer.[503]

Other Jesuitical manuscripts contain less useful images. Panici and Guarini still believed in Linus' theory,[504] but they did not reject the vacuum. In 1699/1700 Panici taught physics at the College of Rome; he described Boyle's experiments, but he was more interested in the explanation of the colleagues Linus and Faber (Fabri),[505] whose textbook the Jesuits used in Ljubljana. Panici acknowledged the pressure of the air and commented Torricelli's famous letter to Cardinal Michelangelo Ricci. In addition to Boyle, Panici quoted Giovanni Alfonso Borelli and the Roman professor Jesuit Benedictis who taught in 1666. Panici was interested in the achievements of Bartoli from Ferrara, who served as rector of the Roman College between 1670 and 1674 and published the biography of Zucchi in 1682.

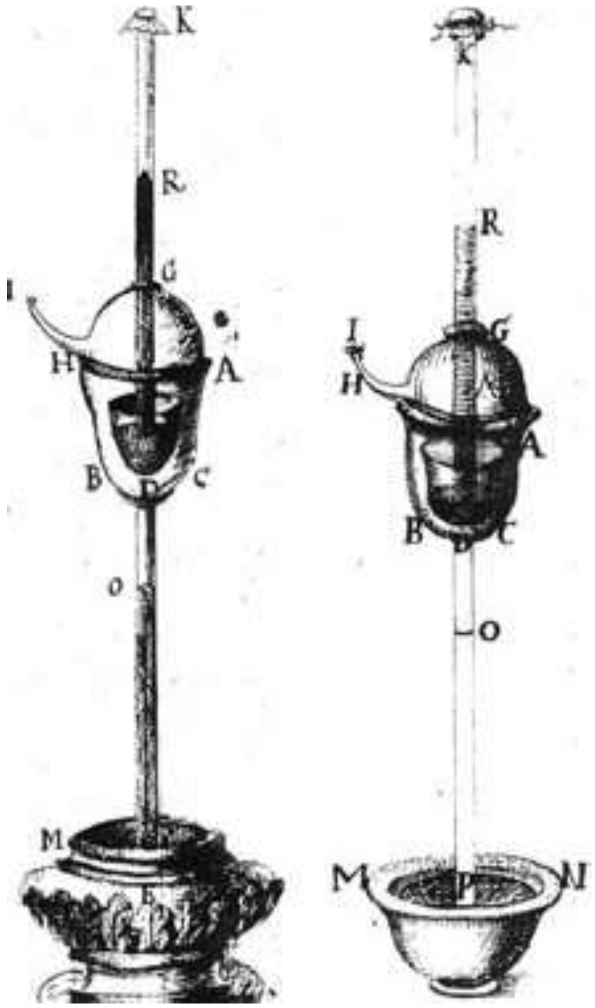

Figure 5-47: Vacuum in a vacuum[506] by Guarini (1706, 341/342)

[502] Rosenberger, 1890, 684; Priestley, Autobiography 1966, 165, 181.
[503] Esteran, about 1720, 311.

[504] Fistulae (Guarini, 1706, 339).
[505] Panici, 1700, 990–992, 996, paragraphs 1242–1245, 1251.
[506] Guarini, 1706, 341/342.

Panici noted the measurements of the masses and densities of air of Galileo, Mersenne and Faber. He examined the experiments of Florentine scientists with mercury and Galileo's experiments with water in support of his opinion on the vacuum.[507] Thus, his description of the vacuum was the basic part of the Physics of Panici. He devoted his last chapters to it.[508]

Guarini was a professor of physics at the College of Siena in 1703 and a professor of mathematics at the Roman College between 1710 and 1712. Six years after Panici, he criticized Descartes's theory of vortexes, primarily because of Descartes's opposition against vacuum. He reported on Torricellian experiment, Magni and Linus. He described Boyle's pneumatic pump and vacuum experiments at the Florentine Academy[509] and, above all, Roberval's theory of vacuum.

Figure 5-48: The Jesuit Barometer[510]

Panici and Guarini taught at the Collegio Romano. Their sketches show devices that were later explained to a young Roman student Bošković from Dubrovnik. Half a century after Panici and Guarini, Bošković's physics assumed a vacuum for one of its foundations. The question of Bošković's vacuum has now been raised in a completely differentiated way than in the earlier dispute between peripatetic and atomists.[511] Bošković avoided the Cartesian linguistic problem of vacuum as nothing. Therefore, for most Jesuits the description of the vacuum in Bošković's networks was the only useful way out of the puzzle that was triggered by the already obvious success of vacuum experiments. The first measurements of heights with barometers were carried out in France on 19 September 1648 and five years later in England. Much less is known about altitude measurements in Italy and the Habsburg Monarchy. Esteran's drawing shows measurements in Italy or in Spain as he served at both places. From Esteran's picture, we can find out how at a certain height of the hill the researchers reported time and direction of winds at the era when they had no portable clocks available yet (Fig. 5-46).

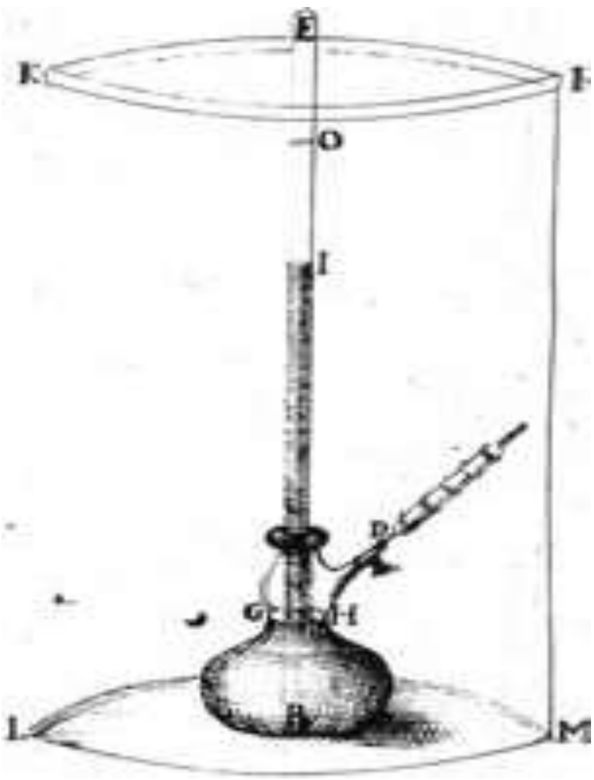

Figure 5-49: Simple Italian Jesuits' Pump[512]

[507] Panici, 1700, 992, 994–995, paragraphs 1246, 1249–1250.
[508] Panici, 1700, 980–998, paragraphs 1226–1254.
[509] Guarini, 1706, 77, 295, 304–305, 309–314, 319.
[510] Guarini, 1706.
[511] Hellyer, 1998, 389.
[512] Guarini, 1706, 341/342 b.

Roberval and Auzout first observed their barometer in vacuum in 1648. Soon after, the experiment was repeated by Roberval's friend Pascal. A similar Boyle's experiment was the one which Schott appreciated the most among all Boyle's achievements.[513] The experiment was termed a "vacuum in a vacuum", and later it was particularly well-known in Huygens's version (Fig. 5-47).

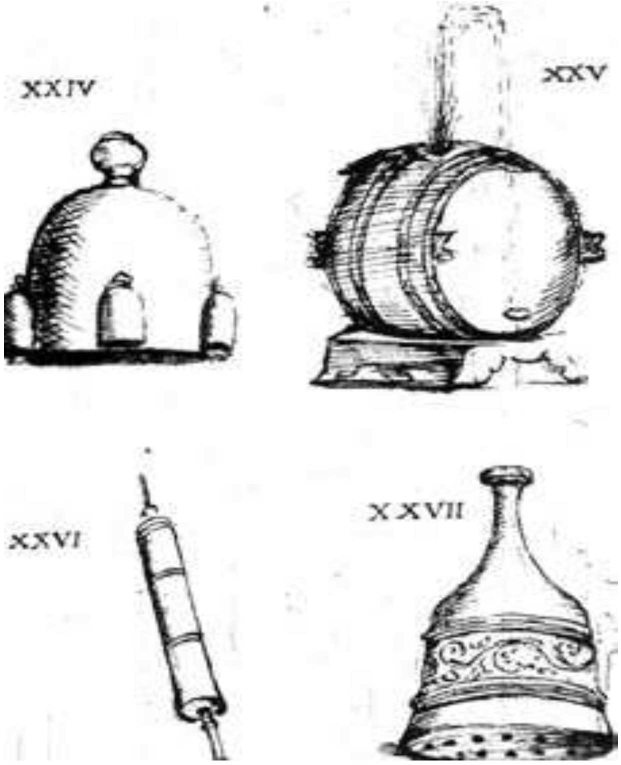

Figure 5-50: Other equally simple Italian Jesuit Pump[514]

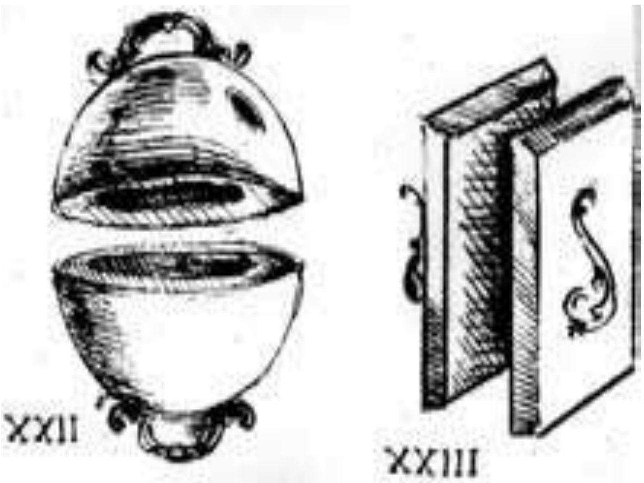

Figure 5-51: The Magdeburg hemispheres.[515]

[513] Boyle, 1965, 1: 33–39, 168–169 (17th experiment and its defense against critiques); Hellyer, 1998, 288.
[514] Anonymous, about 1700, 181.

Guarini twice sketched the famous Roberval's experiment for his students.[516] A mercury column dropped when the barometer was placed in a vacuum container. When the air filled the container, the column rose to a level that balanced the outer air pressure (figure 5-48).

Both Guarini and his anonymous contemporary drew simple vacuum pumps like early Guericke's tools in their manuscripts. The details of designs cannot be distinguished in the sketches of Figures 5-49 and 5-50.

Experiments with Guericke's Magdeburg hemispheres were explained within the Jesuit curricula in the chapter on adhesion rather than in the chapter on vacuum. Therefore, the sketches were depicted in experiments with the adhesion of two marble plates (Figure 5-51).[517] Centuries later, J. Stefan proved that the adhesion of two marble plates does not involve forces between the invisibly small constituents which were proposed earlier.

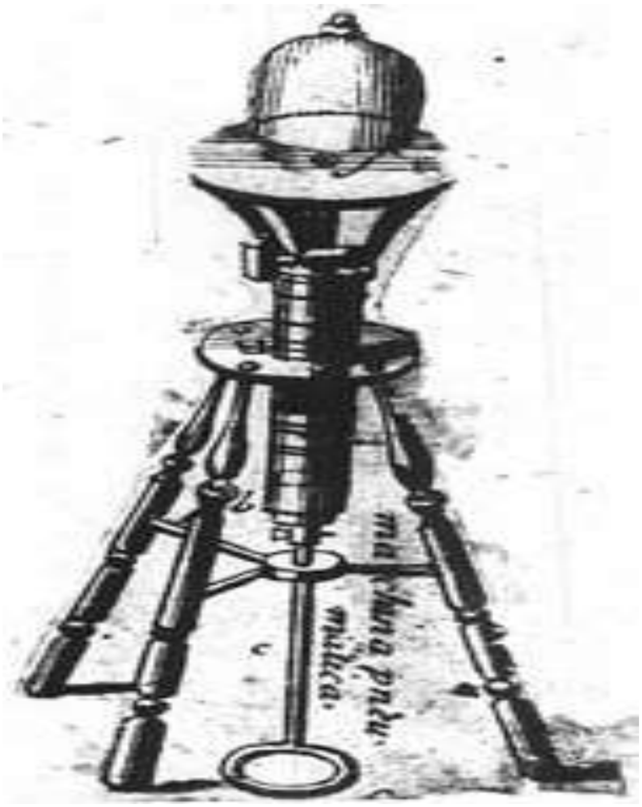

Figure 5-52: Italian Jesuits' Vacuum Pump[518]

[515] Anonymous, about 1700, 181.
[516] Guarini, 1706, 333, 342; Middleton, 1964, 48–49, 54
[517] Esteran, about 1720, 406 left; Anonymous, about 1700, 181.
[518] Esteran, about 1720, 32.

Esteran's vacuum pump[519] was not quite the same as the pumps which Hooke had assembled for Robert Boyle in Oxford and London in the late 1650s and in the 1660s, nor even to those which Papin designed in the second half of the 1670s. Esteran's vacuum pump was even more distinct from older Guericke's pumps (Figure 5-52).

Esteran named his device as "pneumatic" by Boyle and also separately sketched each of its components. Like Boyle in 1669, Esteran drew and recorded dozens of experiments in a emptied receivers. In the vacuum, he observed the eventually changed activity of the balance, waterway fountain, suffocating of animals, ringing, adhesion, barometer, magnets and much more (Figure 5-53).[520]

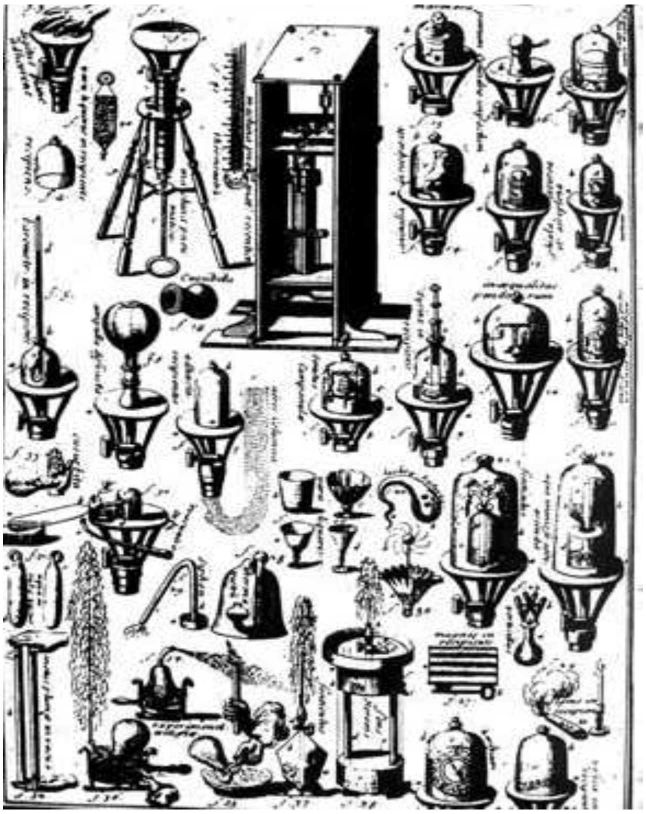

Figure 5-53: Jesuitical experiments in a vacuum[521]

Panici's Pumps in the College of Rome closely resembled the first and second Boyle's devices. The first Panici' sketch differed primarily in the shape of the frame and with its different design of the shut-off valve under the vacuum container. There were some differences with the cover of the container, which is not well visible on the Panici's sketch. The other Panici' sketch differs greatly from second Boyle's pump depending on the shape of the frame, the vacuum container and the movable parts (Figures 5-54, 5-55 and 5-56).

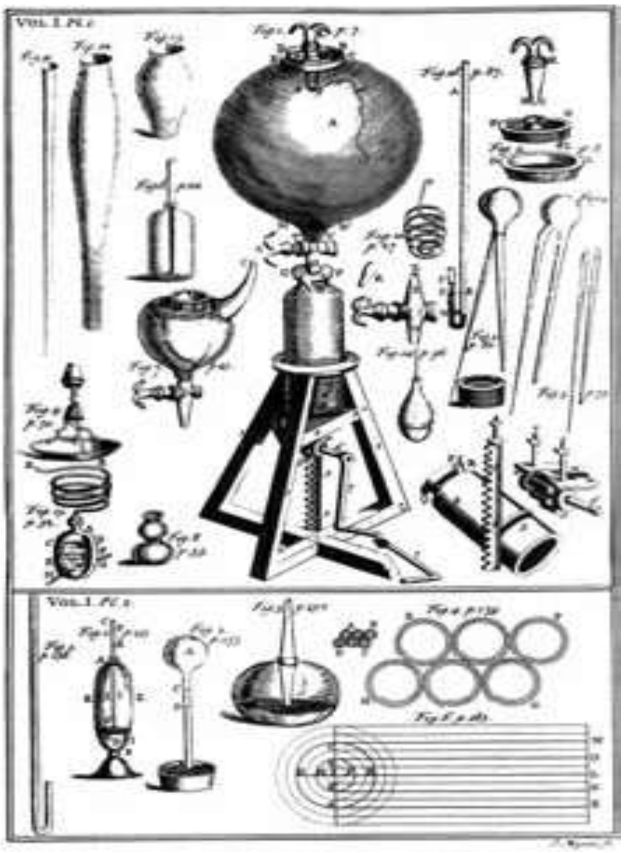

Figure 5-54: Boyle's pump[522]

Before our discovery which described the sketches of Jesuit professors in the Italian province, the researchers preferred their false opinion that Torricellian vacuum was mainly used in Italy under the influence of Galilean pupils from the Florentine Academy. Since the vacuum in the barometer was better than the vacuum of Boyle's pump, the Italians were supposedly not particularly interested in the pump, which would otherwise allow them to conveniently set up experiments with a much larger space for their execution. In Florence, Guericke or Boyle's pumps were not made, although the Tuscans knew their composition. The secretary of Florentine academy, Magalotti, was personally convinced of the advantage of Boyle's device in eliminating bubbles in a vacuum in England in 1678. The information spread mainly through personal contacts and books; so, the Florentine academics have argued

519 Esteran, about 1720, 32 left.

522 Boyle (1660), 1965, 86/87.

that their own vacuum devices are as good or even better. The opinion was created as based on the early reports of pioneering Boyle's work, much like Boyle's underestimation of Guericke's pump.[523] Apparently, at least in Rome, they tested Boyle's and similar pumps.

There are still many white spots left in the historical development of early vacuum devices. Since the devices from the 17th century have not been preserved, many details have been lost to oblivion. The manuscripts of the Italian Jesuit professors help us to fill the gaps in the knowledge of the experiments with which our ancestors proved the existence of a space with reduced pressure (Fig. 5-57).

6 Books about Vacuums

6.1 Vacuum among Carniolans at End of the 17th and in 18th Centuries

6.1.1 Vacuum Books in Ljubljana at the End of the 17th century

The oldest data on the knowledge of vacuum in the former Carniola is illustrated by the relative prevalence of the books about emptiness. In May 1678, Mayr's catalog of books offered 2566 titles of different topics to Mayr's clients in Ljubljana. Mayr put up for sale the works of the then most important Jesuit researchers of vacuum: four Kircher's books, letters and two other Fabri's works,[526] and six books of Würzburg professor of mathematics, the Jesuit Schott. Among the researchers of the vacuum outside the Jesuit order in Mayr's offer there were mainly three Boyle's books, among them the Tractate about Air with experiments in vacuum. In addition, Mayr offered the most important scientific journal, Phil. Trans. with Boyle and Newton's discussions published there (Fig. 6-1).[527] This was the newsletter of the RS whose member became Carniolan Valvasor nine years after Mayr's printed offer.

Among the Schott's books in Mayr's offer, we miss a work "Hydraulic pneumatic mechanics", where in 1657 Schott first described the Guericke pump. For this reason, Mayr offered Technical Specifications from 1664, where Schott described in the first part the experiments with Boyle and Guericke's air pumps. The rich residents of Ljubljana were able to buy Schott's brand-new work on Magic, where in the 7th book on gas experiments Schott described the Jesuit exploration of the vacuum and the experiment with Magdeburg hemispheres (Figure 6-2).[528] The richly illustrated book was, of course, purchased by the Jesuits of Ljubljana as it proved the reality of the Auersperg Prince's Regensburg stories.

Between 1655 and 1663, Schönleben, the son of a Ljubljana mayor, cataloged the books of the prince's elder brother, the Auersperg Count Wolf Engelbert. He had the first edition of Kircher's Great Art (Ars Magna), whose second edition Mayr offered to the citizens of Ljubljana a few months after the death of Prince Janez Vajkard. In 1697, Auersperg gave his copy of the Great Art (Ars Magna) to the Jesuits of Ljubljana, who were just preparing for the opening of Ljubljana's higher studies. In that book Kircher examined Torricelli's experiment with a mercury barometer.[530] Already for two centuries, mercury was dug in the Idrija mine; so, the experiments with it were especially important for Carniolans. We do not know how many books the residents of Ljubljana bought at

[530] Kircher, 1664, 26–29; Mayr, 1678, 79.

Mayr's shop, since we know the catalogs of most larger libraries in Carniola only for the 18th century while only Valvasor's listing and the legacy inventories are relevant for earlier data of late 17th century. Certainly, the offered books on vacuum show that Carniolan ancestors were interested in vacuum puzzles very early. Boyle's works sold in Ljubljana still apply today as a key to the foundations of modern physics, chemistry and vacuum techniques; Ljubljana was not the provincial city three centuries ago without contact with the progress of vacuum research in the European centers of the time. Most of the books were purchased by the son of the first Auersperg prince and the son of his knighted tax collector, Franc Jakob Erberg, elder brother of Janez Danijel Erberg (Table 6-1).

6.1.2 The Vacuum Related Instruction at the Jesuit College in Ljubljana (1706 -1773)

6.1.2.1 Students Start Learning about the Vacuum

The younger sister of Janez Danijel Erberg, Maria, was married to the nobleman Matija II Jenčič. Shortly after the marriage, in 1674, Matija became the manager of the Auersperg's castle Poljane by Kolpa river. His son, the physicist Sigmund Jenčič, taught at the college in Ljubljana between 1701 and 1705 and again between 1713 and 1718. He must have remembered his uncle's stories about Auersperg's and Guericke's experiments. Therefore, in the thirty-five exams queries, his physics students of physics in Ljubljana learned the differences in the density of substances that enabled the operation of vacuum pumps.

In the Jesuit College in Ljubljana, they began to teach physics in 1706. Anton baron Erberg from Dol by Ljubljana, the first cousin of Sigmund Jenčič and son of Janez Danijel Erberg, was the first domestic author of the textbook about physics in Carniola. Anton was a professor in Ljubljana and during the last two years before the death even the rector of the Ljubljana College. He wrote General and Special Physics in Aristotelian Chapters[531] modified for the Maria Therese's Reforms, which were printed only posthumously after Anton Erberg passed away.

In the first part of the conversation On Creation and Decay, Anton Erberg cited his own and the scorned Magni's works. In the second part, he addressed the physical changes of substance. He listed the vacuum experiments of Torricelli, Huygens, Boyle and Guericke. He heard a great deal about Guericke's and Auersperg's experiments in Regensburg from his father, and he did not completely shake off Aristotle's and Auersperg's doubts about the possibility of moving any stone through a complete vacuum. He has denied the possibilities for the existence of a vacuum and, in contrast to Magni, ensured that in the body there cannot be a completely empty space.[532] The opinion was still quite widespread in the time of A. Erberg's youth, but upon the publication of his book it had already become obsolete after the vacuum in steam engines became the leading industrial motor.

6.1.2.2 Erberg's Concept of Vacuum, his Collection of Textbooks and Experimental Tools

Anton Erberg's nephew Hallerstein together with his colleagues presented for the first-time their vacuum experiments to the Chinese Emperor in 1773. At that time, the great grandson of Prince Janez Vajkard Auersperg's brother, Herbert Auersperg, became the professor of special and general physics in Ljubljana in 1770. Anton Erberg's first cousin, B. F. Erberg, published the translation of Physics of magnets of the famous Dutch physicist P. van Musschenbroek in Ljubljana in 1754. In the same year, at least three Musschenbroek books were purchased at the college in Ljubljana, among them Essay on Physics, where he dedicated an entire chapter to an empty space. In contrast to Cartesians, Musschenbroek argued that empty space is much more than a space without a substance. He thought that the water was cooling faster in an empty space than in the air, which was incorrectly proved by stopping of the burning in an empty space. The mistake was due to the ignorance of the role of oxygen in combustion, which was investigated only by Priestley, Scheele and, above all, by

[531] Hellyer, 1998, 374.

[532] Erberg, 1750. 2: 351–353; Erberg, 1751, 2: 47, 351–353, 3: 151, 161, 492–497.

Lavoisier. All of them succeeded after A. Erberg's death.

Pieter van Musschenbroek was born in Leyden in the Protestant Flemish family which retreated to the north to avoid religious exoduses. By 1715 he studied philosophy, mathematics and medicine at the University of Leiden in the Netherlands. His best teacher was Boerhaave, a professor of medicine, botany and chemistry at Leyden since 1708. Pieter van Musschenbroek then went to visit Newton in London. He continued his studies in Germany, where he received his doctorate in philosophy in 1719 and became a professor of philosophy and mathematics at the University of Duisburg. He was experimenting in his classes. Between 1723 and 1739, he taught at the University of Utrecht and in 1734 he issued a famous textbook of physics in the Latin language, which was published two years later as the first physical work in the Dutch language. In 1732 he received the Astronomy Chair in Utrecht, and in January 1740 he accepted the Leiden Chair of Philosophy.

The vacuum pump was an integral part of every better laboratory in the century after its invention, like the later Leyden jar.[533] We know very little about vacuum pumps at the Jesuit College in Zagreb.[534] According to the catalog of manufactured scientific devices published by Johann Gabriel Doppelmayr's student Brander from Augsburg in 1753, the cheapest vacuum pump was worth 150 to 175 florins, together with the associated glass parts. The other pump costed 250 fl, and the costliest was sold for 350 fl. The most expensive pump was made according to the plan of 'sGravesande, the coworker of P. van Musschenbroek in Leyden. The microscopes were much cheaper, as only 30 to 40 florins[535] had to be paid for them. On 17 September 1755, B.F. Erberg as the professor of mathematics enumerated the fifty-five instruments needed for the teaching of mathematics and physics in Ljubljana. They averaged the prices of 50 florins, but later the Jesuits received yearly as much of half of that price for their maintenance. So, the people of Ljubljana could not afford to have more vacuum pumps which were at last three times more expensive than the average tools.

B. F. Erberg was a professor of mathematics, philosophy and physics at higher studies in Ljubljana between 1751 and 1758. From his student years he preserved the undated manuscript of Physics, in which he dealt with air and with the fear of vacuum. He devoted ten chapters to the explorations of vacuum, overpressure and air resistance. Among his favourite experimental devices was a pneumatic pump with its own vessel and a double piston needed to exhaust the air from the container. With a similar device, Boyle has already proven that the vacuum does not translate the sound. In his Ljubljana experiments with the pump, Erberg also glowed his metallic plate and demonstrated the transfer of thermal radiation through a vacuum. The pump had a special lamp. A resinous mixture of lead and silver was used to seal the emptied receivers. Thus, six Erberg's devices in his Ljubljana lab formed a vacuum experimental kit (Figure 6-3). Guericke's Magdeburg hemispheres were used to display the air pressure.

Thus, the grandson of the prince's customs officer, B.F. Erberg, acquired a Magdeburg hemisphere of Auersperg and Guericke for teaching at the Jesuit's college of Ljubljana a century after the original experiments in Regensburg. At least then, if not during the time of the first Auersperg prince, they could repeat Guericke's experiment four hundred miles south-east of Regensburg, in white Ljubljana. The Magdeburg hemispheres were enumerated again in 1811 among the instruments for the study of hydrostatics and in 1847 among the instruments for the exploration of gases. The device from 1755 was replaced by a new one made by the Ljubljana bell-foundry of Samassa. In the following years they wrote off the Samassa's Magdeburg hemispheres, which were not listed in the census in 1866. The third Guericke's hemispheres in a more modern version were acquired for the Grammar School in Ljubljana in the school year 1867/68. After 1755 in the college of Ljubljana the Jesuits used Heron's bronze fountain to demonstrate the lifting of a stream of water with compressed air, which was already known in ancient Alexandria. Erberg also obtained

[533] Leyden jar was an earliest usable electric condenser. It got its name by the Dutch university where P. van Musschenbroek taught as one of the inventors. After his first experiments he got such strong electrical shock that he refused to repeat it by any chance.
[534] Dadić, 1982, 2: 240.
[535] Hellyer, 1998, 309.

a barometer for meteorological observations and a Cartesian diver, attached to a semi-transparent hollow ball, which, under pressure on the tube stop, descended from the surface to the bottom of the liquid. Erberg also purchased Heron's copper sprinkler. Like Magdeburg's hemispheres, both Heron instruments were written off before 1866. However, in Heron's case, they did not acquire new devices that apparently no longer fit modern curricula. Erberg's "Barometer for Meteorological Observations" was used in 1811, when Kersnik listed the teaching aids at the Central Schools in Ljubljana.

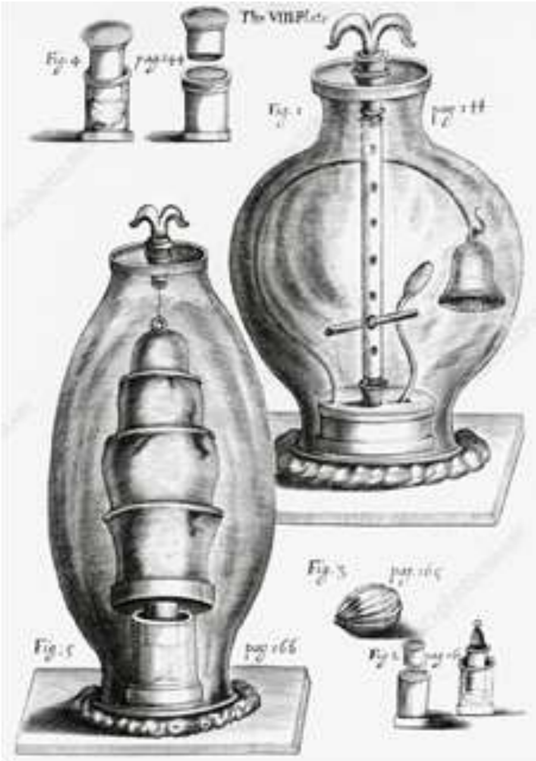

Figure 6-3: Woodcut from Boyle's book with an experiment of ringing in a vacuum, as it was shown to the students in the Jesuit College in Ljubljana after 1755.[536]

6.1.2.3 Taufferer's Edition of Mairan's Book

The Rijeka (Fiume) native Tricarico taught physics in Ljubljana in 1757. Two years earlier, he printed his thirty examination theses in Graz, among which he laid the theses in physics after his eleven theses from metaphysics. After describing the difference between physics and chemistry, students had to prove the existence of a vacuum and its distributions in the world. After his theses, he printed the popular physics conversations of the French Jesuit Cartesian Regnault. He described Torricelli's experiments with a mercury barometer, the rejection of the fear of emptiness in books of Galileo and Kircher, and the experiments of Pascal, Mariotte, Boyle and Guericke with a vacuum.[537]

In 1760, the professor of physics Taufferer from Turn by Višnja Gora printed nineteen exam theses from the general and the same number of theses from special physics. He finished the examination with two theses about biology. The theses were defended by Škofja Loka natives Anton Feichtinger and Alojzij Vermati de Vermesfeld, where for the first time in the history of Ljubljana schools they publicly supported the Copernican system. Taufferer explained Torricelli's experiments with barometric tubes, an elastic ether and an empty space in the body pores. The small body particles are supposed to generate heat and sound with oscillation, and there should be an empty space around them. Dilution of the body is due to the spread of the pores (cavities) caused by the ingress of countless particles of fire. Similarly, thickening should be caused by the cavity shrinkage due to cohesion. Due to disorders in the ether balance evaporation of very fine particles from the cavities of the substance is expected. His ideas of a vacuum were noted in the first two chapters of his publications of translation of the book of the secretary of the Parisian Academy Mairan. Taufferer published it in a promoting print bind to his Ljubljana exams theses. Jean Jacques D'Ortous de Mairan (Dortoux, D'Ortous, 1678-1771) described a vacuum in a tube above a mercury column. He dealt mainly with meteorology; only on the first page he described the operation of the vacuum in the barometer and the air pressure.

6.1.2.4 Schöttl's Concept of Vacuum According to Raigersfeld's Records from 1763

Raigersfeld was the Carniolan noble family of the farmers' genus from Rakovica under St. Jošt mountain in Upper Carniola (Gorenjska). From 1761 to 1767 M. Raigersfeld studied law and cameralism at Sonnenfels' class in Vienna. Sonnenfels proclaimed M. Raigersfeld as his most talented student. In 1763 he studied at the elite Theresian Jesuit College in Vienna. There he

[536] Conant, 1958, 75.

[537] Regnault, 1755, 67, 349–357.

listened to the lectures of physics of former Ljubljana professor J. Schöttl, who used the textbook of Hungarian Jesuit Paul Mako.
Raigersfield wrote about the vacuum and pores in the bodies.[538] He first attempted to justify the existence of a vacuum, but only in subsequent chapters he began his mathematical equations. Regarding the vacuum, the Cartesians and Leibniz were opposed to the advocates of Newton and Epicurus. However, in the completely totally filled space, movement is not possible, as there is no space to move in. The vacuum must be between the stars. Raigersfeld and his teachers saw contradictions in the Cartesian doctrine of a subtle ether. He thought it would hinder the movement of the planets. This argument was repeatedly used in the second half of the 19th century. Raigersfeld had pores for a space between two distinguished particles of matter. In the pores there is an infinitely more vacuum than in the bodies themselves. There is also much more vacuum than matter in the pores, and Raigersfeld expressed the ratio between them with numbers. The weight is proportional to the amount of matter; in lighter bodies there is more vacuum. In the background of such thinking he anticipated the later William Prout's assumption of the same atoms with different mutual distance in different substances announced in 1815/16 after the experiments in a vacuum apparatus of Prout's own design.

Raigersfeld's pores in the bodies allow the propagation of sound and light. The particles moving through the substance experience a repulsive force. At other distances between particles, there is a mutual attractive force[539] according to Bošković's theory. Raigersfeld did not mention the new Bošković's work by name because he did not provide much quotations anyway. His professor J. Schöttl and Mako, were among the most enthusiastic defenders of Bošković in the Habsburgian monarchy.

6.1.2.5 The Influence of Bošković's Physics in Ljubljana until 1773

In the 1750s, the Jesuits modernized physics classes at the College of Ljubljana. After 1753, they acquired many books about physics published by non-Jesuitical authors and modernized the cabinet of physics. On March 9, 1758, the famous Jesuit physicist Bošković visited Ljubljana. On his way from Vienna to Venice, he slept overnight after a fine reception at the Jesuit College in Ljubljana (Figure 6-4). Bošković visited Ljubljana at last three times. At that era, physics course in Ljubljana was still a part of the course of philosophy together with metaphysics and logic. Only after 1764 the professors of physics in Ljubljana were no longer alternating every year, but rather they lectured physics for several years in a row. Their physics was also split in its modernized experimental (particular) and theoretical (general) parts.

Figure 6-4: Note in the Jesuit Diarium of the Minister of Ljubljana college on the visit of Ruđer Bošković to the College of Ljubljana on March 9, 1758[540]

In the last decade before the suppression of the Jesuit order, all professors of physics in Ljubljana have been also the advocates of Bošković's physics. According to Bošković, the vacuum was purely imaginary, but not entirely nothing, because it changed completely real distances between masses. The penultimate rector of the Ljubljana College between 1763 and 1766, and again from 1769 to 1772, Dillherr, published Gobart's book about the barometer as a promoter in Graz in 1746. The small format booklet consisted of 220 numbered paragraphs. The fourth among them denied the "horror vacui", and the tenth correctly described the lifting of mercury in the barometer

538 Raigersfeld, 1763, 4–13.
539 Raigersfeld, 1763, 5–13.
540 SI_AS 1073, Manuscripts, I/40 r, page 1742 right.

due to the weight of the air. The descriptions of the experiments of Kircher, Boyle and other researchers followed. In paragraph 104, the possibility of dilution and compression of air with a pump was described.

The Carinthia native Janez Krstnik Pogrietschnig was a professor of physics in Ljubljana between 1764 and 1768. In 1768, he published the theses for the physics examination. His students bound their exam thesis together with the books of the famous authors to promote Asclepi's astronomical discussion and Bošković's physics. The balance of mercury in the barometer was explained without mentioning the vacuum, and the barometer was mainly analyzed from the meteorological point of view. In addition to Pogrietschnig's examinations, in Graz Bošković and Asclepi's works were also reprinted by the Viennese Biwald, the most important writer of textbooks of physics in the then Habsburg monarchy. He taught at the Jesuit College in Ljubljana between 23 October 1755 and 1757 and might have been there again as the student of last year of theology and assistant librarian in Graz, in 1761. His theses for physics examinations were repeatedly reprinted with minor changes. They contained no specific questions about the theory of vacuum, while Biwald's students had to know experiments with pumps, a siphon, and various artificial springs to describe the operation of the barometer. The opaque nature of the bodies was explained by the heterogeneous structure of parts of the body and by the evenly distributed mass particles and empty spaces in the body.

6.1.2.6 Vacuum-related Instruction on Lyceum in Ljubljana from 1773 until its Temporary Closure (Abolition) on 20th October 1785

In 1775, Jurij Vega passed the final exam at Lyceum in Ljubljana after he answered thirty-eight physics theses of his professor Gregor Schöttl, a relative of Janez Schöttl. In 1769 Gregor started to teach physics in Ljubljana.[541]

In 1771, G. Schöttl considered the fluids in general, and he especially focused water and vapor, but he did not mention a steam engine nor a vacuum. In 1775, Vega and other students provided a description of matter, which, in addition to the substance, also forms pores with a vacuum included. The students described the spread of light through a vacuum, referring to demonstration experiments with two decades previously acquired devices that they observed during their lessons (Figure 6-5).

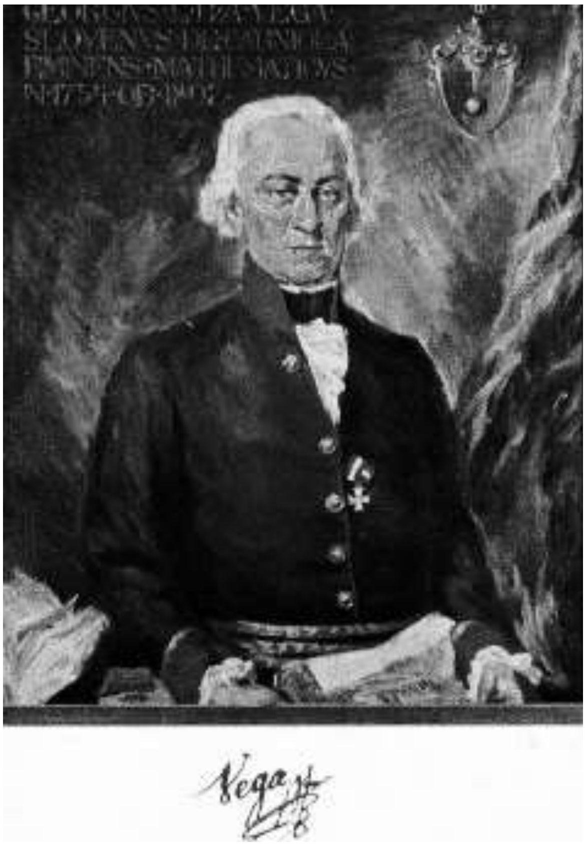

Figure 6-5: Jurij Vega (* 1754; † 1802)

Later Vega used the knowledge gained during his studies in Ljubljana. In 1800, the whole chapter of his textbook was dedicated to air pumps and presses consisting of piston, communicating vessels, recipients, and pipes. He specifically described Torricelli and Guericke's experiments with hemispheres. He knew that Guericke pump couldn't possibly achieve such rarefied air comparable to the vacuum in Torricelli's barometer. He described a dozen vacuum experiments using air pumps:

1) The height of the mercury column increased with pumping out the air above it.

2) He rarefied the air in the tube so that mercury went into an open pipe connected to a mercury container. When he released atmospheric air into a tube, mercury dropped down into the container.
3) As the air was pumped, the external pressure on the glass container's wall rose. In the case

[541] Schöttl, 1775, 33–52.

of large dilution, the deformation of the container may have occurred.

4) By allowing the atmospheric air into the emptied container, he levelled the external and internal pressure.

5) He described the Guericke's experiment in which 15 horses on each side, without any success, pulled the evacuated hemispheres.

6) The candle extinguished, and the poor animal choked in diluted air.

7) By diluting the air, he reduced the volume of the sound of the bell in the vacuum so that the ringing of bell was almost completely dried off.

8) He described the Cartesian diver which he had already used during the physics lesson in Ljubljana.

9) Despite the strong dilution of the air, the water in the recipients is only slightly heated during pumping.

10) Beer, milk and yeast secreted a lot of air bubbles in diluted air.

11) Some water evaporated when he considerably diluted the air above it. A completely transparent vapor was liquefied on the walls when he let the air into the container.

By weighing the emptied hollow sphere, he proved that the air had gravity. The bodies were heavier in a vacuum without buoyant force, which would counteract force of the gravity.[542]

After the suppression of the Jesuit order, physics at Lyceum in Ljubljana was taught by the former Jesuit Ambschell from Györ in Hungary for half a dozen years in 1778-1785. He was an enthusiastic advocate of Bošković's physics. He examined the barometer and empty spaces to make it the subject in his examinations. As the Ljubljana Rector, he was unable to prevent the temporary abolition of the Lyceum which remained closed for several months due to the Josephine centralization reforms.

6.1.2.7 Vacuum in Physics Classes in Ljubljana in the First Half of the 19th Century

After the reestablishment of Lyceum in Ljubljana on 24 April 1788, physics was taught by the former Jesuit Jernej Schaller, born in the Viennese suburb in 1745. After his illness, he was replaced by Neumann from Moravia from 3 March 1803 until autumn 1806. Later, Neumann became the professor of popular astronomy and physics at Joanneum in Graz until he went to Vienna. Neumann published a Compendiaria Physica textbook in Graz from 1808 to 1812; in the German translation it became the Lehrbuch der Physik. The book was purchased immediately after the print for the Lyceum Library in Ljubljana. The former Neumann's Lyceum student Kersnik, a grandfather of renowned writer, used it in his Latin physics classes for the freshmen at the Faculty of Arts of the Academy of Ljubljana in 1810/11. Kersnik is one of the most proficient physicists in Slovenia, because he taught physics since 10. 12. 1808 until his death; almost forty-two years. During the French occupation, he was a professor of physics at Écoles centrales in Ljubljana, the capital of the Illyrian Provinces. In 1811, he catalogued Magdeburg hemispheres and other devices in the physics-chemical cabinet in Ljubljana. After the restoration, Janez Kersnik taught physics at Lyceum in Ljubljana according to the textbook of the Piarist Remigio Döttler. Döttler took over the lectures of physics and mechanics at the University of Vienna after Ambschell (1804-1809) and retained the chair until his death in 1812. Döttler's textbook was not based on Bošković's dynamics anymore, but it still distinguished between general and special physics. Guericke's experiments, the consequences of dilution and air compression and the production of various Torricelli tubes or barometers were discussed in the first chapter of special physics.[543]

For a half of decade, Hummel from Moravia was Kersnik's colleague in Ljubljana. Hummel taught the elementary mathematics in the first year of Lyceum in Ljubljana from 1835 until his departure to Graz. In 1850 at Graz University, he became the first professor of physics and retained the chair until his retirement on 31. 5. 1867. Before his appointment to post of a substitute (suplent) teacher, and in 1837 as a full professor in

[542] Vega, 1800, paragraphs 62–66, 70–74, 76, 80–82.

[543] Döttler, 1815, 1: 12–15, 33, 2: 4–25.

Ljubljana, he made a device for the improved fermentation of wine and beer in 1821.[544] In the fermentation machine, he used gaskets and recipients that were characteristic of the then vacuum and overpressure devices (Figure 6-6).

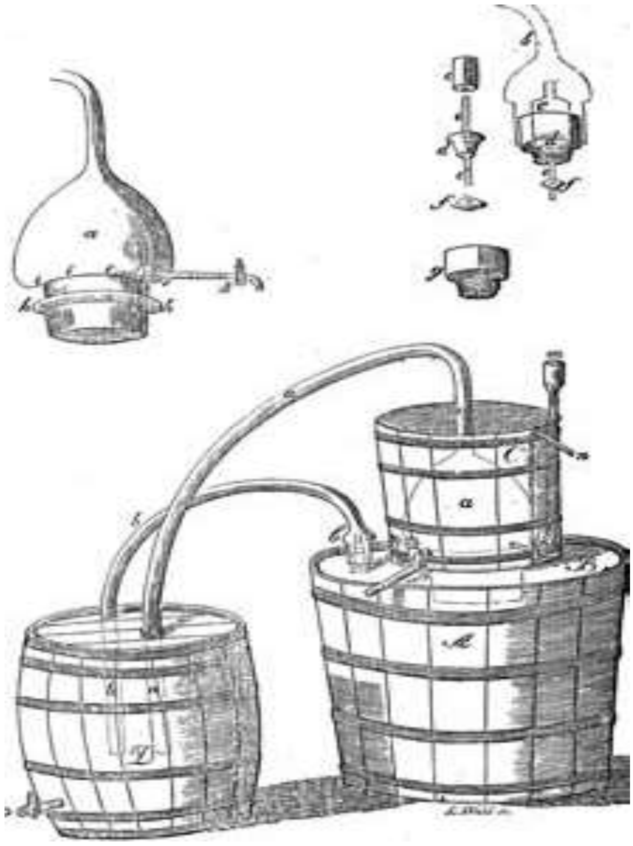

Figure 6-6: Hummel's Machine for the fermentation of wine.[545]

6.2 Vacuum Related Books on Slovenian Soil

What was the education of the first Slovenian vacuumists? We will find the answer in books with descriptions of vacuum techniques of their times, but we will be able to tell less about vacuum devices in the then Baroque Ljubljana. Janez's brother Wolf Auersperg has filled one of his Ljubljana's rooms with unusual devices like "chamber of wonders" as Kircher did in Rome, but there is not enough information about any Wolf's vacuum devices in it. So, we have the first explicit proofs of the school's vacuum experiments in Ljubljana only on 17 September 1755, in Ambschell and Schaller's catalogues, and from 1811, a century after Auersperg's cooperation with Guericke in Regensburg.

Auersperg's library in Ljubljana might be the greatest private collection of his era, but the bulk of knowledge of his neighbours was still concentrated in local monastic libraries. The Slovenian ancestors were the descendants from Latin culture although their linguistic drastically changed. After the collapsed fall of Roman Empire, there was a long silence and disastrous lack of any great eruditions. Mostly through the preserved ecclesiastical Christian organizations the Slovenian ancestors soon met again with Latin culture which somewhat vanished after the collapse of Rome. They learned their forgotten erudition through the Benedictine monasteries in Štivan near Devin (Duino) from the 4th century to the 6th century, as well as from 7th century up to the 4th of July 1289 at St. Peter in Salzburg, where the Irish monk St. Rupert founded a monastery around the year 700. The Irish missionary methods were based on adapting to local conditions, which were later borrowed and developed by Matheo Ricci and his Jesuits in China, while the Irish folks resembled Slovenians in many aspects of their political and religious struggles in the following centuries except that the Irish hated master were English while the Slovenians had their similar troubles with racist Germans as well as with their own renegaded Quisling Germanized folks. The Irish encouraged regular reading of their faithful believers for the training and education of their souls. The Green Irish island was thus a bridge to the knowledge of the new Slavic settlers in Slovenian countries.

One of the most important then-existing libraries in the Slovenian lands belonged to the Cistercian monastery in Stična. Between 1140 and 1473 a Benedictine monastery in the Upper castle (Gornji Grad) in southern Styria was operating, and from 1183/84 the important Cistercian friars settled in Monošter (Szentgotthárd) on the former Slovene territory of today's Hungary.[546] Among the most important libraries in the Slovene areas was the Cistercian stronghold in Stična, where the monasterial theological school and scriptorium was established in 1136 with the founding charter of the Patriarch of Aquileia named Peregrinus (Peregrin).

The most abundant libraries with scriptwriting had the strictest Carthusian order of the Catholic Church. Their particularly rich libraries and scriptoriums were successively established in their four monasteries in Slovenian Lands. We do not know (yet) how to explain why such an interest of the Carthusians for Slovene ancestors; in any case, the actions of the Carthusian monks have greatly increased the level of astronomical, mathematical and literary education in Slovene places. However, the functioning of the Carthusian monks significantly raised the level of Natural History, mathematical, and literary education in Slovenian Areas.

As could be expected, most of the books including those related to the vacuum were initially kept in monastic libraries, which was especially true for now Slovenian areas where the monastic literati remained almost the only ones until the Renaissance. During the Habsburgian centralizations of Josef II, several monastic libraries were disowned with their books officially transferred to Vienna or to the Lyceum library of Ljubljana, but in facts many books were stolen. By the lucky coincidence even if many of these books are not in our evidence now, we still have access to the several variants of their catalogues to enable our search and valuations of knowhows about vacuum among the early monks living at the areas of now Slovenian state. Certainly, far the most important library in the Slovene area was the Cistercians' library in Stična which was also sadly victimized by Josef's imperial reformers.

6.3 Books on the Vacuum once Owned in Cistercian Library in Stična of Lower Carniola

6.3.1 Introduction

Among the most important libraries in the Slovene area was the Cistercians' library in Stična. In 1136, the Patriarch of Aquileia Peregrin issued the founding charter of the local monastery with a theological school and scriptorium.[551] Six years later, the Cistercians founded a monastery in Vetrinje, which had similar significance for Carinthia (Koroška) and nearby Upper Carniola (Gorenjska) as Stična had for Lower Carniolan folks (Dolenjci). Especially rich scripting libraries have developed the strictest Carthusian order of the Catholic Church who established four monasteries

[551] Bahor, 2005, 100.

in later Slovenian places: Žiče (1164), Jurklošter,[552] Bistra (1260) and finally Pleterje[553] of the Count Herman of Celje, who acquired the emperor himself for his son-in-law.

Pleterje monastery was abolished after its internal problems in the Protestant era in 1596, and the whole property was transfered to the Jesuits of Ljubljana.[554] Only God knows the reasons for so much interest of the Carthusians for Slovenian ancestors. In any case, the actions of the Carthusian and Cistercian monks greatly raised the educational level in later Slovenian towns.

In 1576, 418 books with more than 650 texts were listed in the Stična monastery.[555] The Abbot Maximilian Mottoch served in 1660-1680. He edited a library and archive. After him, the library was led by Janez Kočevar, Francis Plehan, and in the 18th century by Placid Peternel, Evgeny Wernegkh, Robert Kuralt and Bernard Schuderbach. Today the NUK stores the inventory compiled at the time of the abolition of the Stična monastery in 1784. It lists 2663 volumes,[556] which, unfortunately, today unknown Cistercian divided between ten expert groups starting with bibles.[557]

The Aesthetic books followed,[558] and after them the historical books;[559] The fifth group listed the sermons.[560] The fourth expert group is most interested in us as it included philosophical and physical work, descriptions of medical sciences and classical manuals under the reference codes SS and T.[561] It contained 263 works on philosophy and medicine and dictionaries. Of course, philosophy still included naturalistic works with numerous explanations of Aristotle's physics; then natural science included general science, medicine, pharmacology, astronomy, physics with vacuum experiments, chemistry, including even superstitions. The mathematics and physics-based work in Stična originated mainly from the former private library of the secular priest turned Cistercian Florjančič.

In 1783, on the General Cistercian Chapter, the abbots encouraged the heads of regular posts to purchase books in the field of physics, mathematics and sciences, and especially the useful works of horticulture with forestry. At the abolition of the monastery, there were about thirty mostly Latin medical works in Stična. The monks read much less German or Italian books. More than a third of medical books were printed in the 16th century. Among the Stična codes of 12th Century they kept the various scriptures of the Irish monk Baeda Venerabilis (Bede, Beda, * 673 Jarrow in Durham; † 735 Jarrow) *Commentarius in Matheum (Explanatio super Matheum), Expositio in Libros regum* and *Varia*.[562] which testifies to the early visits of Irish monks to Slovenian medieval ancestors. The oldest printings among Stična Incunabula were authored by Regiomontanus, Arnoldus de Villanova's Venetian incunabula Opera medica et chururgica (1490),[563] and a year younger the most popular witty Boethius physical reflection of De consolatione philosophica[564] which was the most beloved among Carniolan high society readers.[565]

Arnoldus de Villanova (Arnaldus, * about 1235 near Valencia; † 1311 at sea between Naples and Genoa) learned Greek and Arabic at home; he successfully treated the Pope Boniface VIII, wrote about the philosophical stone, among the first distilled alcohol and described the carbon monoxide during the smoldering. The Ljubljana Lyceum Library also acquired its Venetian translation of Avicenna with Averroes' comments *In fine expletus est liber primus canonis quem princeps aboali Abinsceni de medicina edidit. Translatis canticorum Avicenne cum commentaris Averrois* issued in 1489.[566]

The Ljubljana Lyceum Library took over the books of the Carthusian monastery in Bistra five years after its abolition in 1782, together with the library of the Kostanjevica monastery. According to the census, the library in Bistra upon the abolition of

Slovene naturalist **Ivan Dizma Florjančič de Grienfeld** (Janez, * 1. 7. 1691 Ljubljana; † 1758) was the son of a lawyer in Ljubljana the member of Academia Operosorum Ivan Štefan Florjančič de Grienfeld (* 1663 Ljubljana; † 1709 Ljubljana). Ivan Dizma completed philosophical-physical and theological studies at the Jesuits of Ljubljana. He was delighted with his professors' scientific sophistication that he even entered their order for two years, just like his father before him. Between 1733 and 1738 he was a priest in Šmartno pri Litiji where he arranged an observatory of astronomical phenomena and magnetic declinations. In next decade, he was a priest in St. Vid, near Stična, and before his death he found the last peace as a Cistercian in the neighboring Stična. In any case, he was among the most educated Cistercians in Stična, the most prominent in natural sciences and vacuum techniques; a large part of the monastic physical reading is adorned with his inscription on the bookmark. He left his own manuscripts, vacuum books and other books. He used Vlacq, Strauch and Sturm's tables, learned Wolff's mathematical technique. He used Winkler's book about the electricity, and Matheseophilus's solution of the ancient quagmire of the squaring of the circle (1733), which Florjančič strongly rejected in the manuscript. He also used five-hundred thirty pages long Johann Leonard Rost's (* 1688; † 1727) astronomical guide with fourteen sketches (Nürnberg 1726), which was finally enlarged by fourteen pages full of images. In the end, in the research enthusiasm, he stuck with the notes for the year 1700, for 1753, and for the day July 6, 1753. Then he observed the eclipse of the first satellite of Jupiter. He added on both sides written leaf list full of data about the Polar star and Tycho's constellation of stars noted for 1717; among them Florjančič was specially interested in Andromeda. It is quite probable that the Cistercians in Stična inherited from Florjančič's legacy also Jacques Cassini's (* 18 February 16; † 15 February 1756) Parisian mathematical writings (1749) and today lost Kepler's Rudolphine tables, which had been on sale in Ljubljana over a decade before Florjančič's birth in Ljubljana.

the monastery had 2900 books and manuscripts.[567] Similarly, the Stična library was only taken over six years after the dissolution in 1784. The most beautiful Stična manuscripts from the second half of the 12th and the beginning of the 13th century used to be appropriated by the Viennese court library, but, of course, many were lost or slipped through the fingers of "conscientious" officials. Thus, only about two-thirds of the former library of the monastery in Stična is preserved in the NUK today.[568] Most of the other expensive stuff just – disappeared. According to Ž. Zois' report, a guy could buy a manuscript or even incunabula for a price of 1 kg of bread in Ljubljana in those dunny days.

The last abbot in Stična was Višnja Gora native baron **Franc Ksaver Taufferer**,[569] who had two brothers priests: Jakob Jodok died in 1810 as a provost and canon of monastery of Augustinians in the town of Vorau in Styria northeast of Graz, while Inocenc became an important Jesuit in Ljubljana and professor of physics in 1760. Franc Ksaver studied in Germanicum in Rome between 1752 and 1756 and received his doctorate there. In March 1756 he was consecrated, and in 1764, he became an Abbot in Stična. Despite his Lower Carniolan origins, he took care of every coin of wealth for his reasonably well-built constructions like a guy from the Upper Carniola (Gorenjska) region or the Scotsman would do. His ways of heading of the monastery caused quarrels and the departure of the newcomers like Gollmayer, Kuralt and the later famous Anton Tomaž Linhart. The Abbot even suffered under the humiliating interrogations of Maria Therese's officials as all sorts of triable bothered his poor greedy head.[570]
.

6.3.2 Cistercian Vacuum

The first-class domestic library of Cistercians from Stična was largely supplemented with Florjančič's heritage. The Cistercians from Stična were well established among the Ljubljana scholars and technicians. Thus, a few days after the death of

[567] Minařik, 2000, 578.

[569] Jurij Jožef Dizma (Franc Ksaver) Taufferer (* 22. 3. 1733 Tum by Višnji Gori; † 23. 3/5. 1789 Ljubljana).
[570] Bahor, 2005, 101.

Anton Čokl (Tschokl, * Vienna; † 8 February 1779 Ljubljana), his chair on the Ljubljana Lyceum was taken over by Jožef Andrej Nowak (Novak, Novakh, Baptized as Josef, 1750 Gorizia-15. 4. 1888 Stična).[571] In 1767 Jožef Andrej Novak made regular vows and became a profess of the Cistercian abbey in Stična, which he left for a while during his service in Ljubljana. Despite the simultaneous professorship in Ljubljana, he was an archivist and abbot's secretary when the monastery was abolished in Stična in the year 1784.[572] Besides the archive, he certainly also carefully looked upon the library too. Unfortunately, Novak sharply contradicted the researcher of the vacuum and compressibility of water, the Ljubljana rector Anton Ambschell.

They quarreled for the proof of the immortality of the human soul; therefore, they had to transfer both of their non-gambling souls to Vienna, after the whole of Ljubljana's faculty of theology moved to Innsbruck for a few years while the faculty of philosophy was abolished until the ex-Cistercian Linhart asked for the return of philosophical studies to Ljubljana.

Figure 6-7: Florjančič measuring instruments published along his map of Carniola (1744).

The Stična Cistercians underwent new vacuum and other experiments under Florjančič's influence. They even knew how to predict the weather from the behavior of human fish Proteus fished in the surrounding area, which they nourished for that purpose in the monastery. They told many people about mysterious underground animals Proteus including the owners of the surroundings of Stična, barons Zois. Together with Zois, they worked diligently in the Carniolan Agricultural Society, which in two decades of operation (1767-1787) successfully played the role of the domestic academy, and deeply interfered with the development of Carniolan physics, fertilized by vacuum technique. Every year, the society has been awarding prize-winning questions. In 1767, the very first reward went the manager of the Rifno (Rifnik, Raicheneck, Reichenekk, Reichenegg) estate by Celje south of Šentjur Franz Jamnik. On 23 November 1768, the Society also praised the Jesuit Pogrietschnig's paper on the Common pastures under the motto Labor omnia vincit.[573] Dr. Ivan Jožef Anton von Haymonn (Haymann, Haiman, Haymon, * 1722 Postojna; † 1799 Ajman's (Ehrenau) castle by Sveti Duh by Škofja Loka), together with the procurator and prelate of the monastery in Stična, evaluated the answers. Postojna Jew Haymonn from the old Carniolan family wrote papers about fertilization, just like Pogrietschnig;[574] of course, the Cistercians in Stična did not forget to acquire Haymonn's books, perhaps during his collaboration with the prelate of Stična In 1757 Haymonn studied his first year of theology in Graz. In the following year he was promoted to the Doctor of Medicine in the imperial

Figure 6-8: A hunter with an air belt around his hips crosses over water with a gun and a game for his dinner.[575]

[571] Novak (Schmidt, 1963, 165, 269).

Vienna with a dissertation on air, various gases and vacuum. On this occasion, he thanked the Empress' Minister Gerhard van Swieten (* 1700; † 1772),[576] and quoted Hippocrates, Jean le Clerc's (* 1657; † 1736) Histoire de la Medicine, Bernardino Ramazzini's Dissertation, de Const. (De Constjtutjone [sic] Anni M. DC. LXXXX. Ac De Rurali Epidemia, Quæ Mutinensis Agri, & vicinarum Regionum Colonos graviter afflixit, Dissertatio) printed in Modena in 1691 and especially the famous Boerhaave's Inst. Med. with the description of the heat of the air.[577] He examined Mariotte's research of the increase of air resistance with the square of the velocity of the projectile; he quoted Johann Rieger's Introd. Rer. Natur.,[578] instructive Swieten's observations of animal behavior in a vacuum,[579] mercury barometer, Réaumur's experiments, Stahl's exploration of burning, Fahrenheit's thermometer and scented evaporations.[580] In fact, Haymonn's dissertation contained more physics than medicine; the wise man successfully practiced in Carniola, and he paid special attention to the equipment and business of pharmacies, so that before 1774 he became a medical councilor and protomedicus as a specialist of urologic and obstetrics. He married lady Angerburg whose father Janez Adam Gottfried Dinzl von Angerburg (* 9 November 1720 Zgornje Perovo) gave him the castle which got the name Ajman by Slavic misspelling of Haymonn's name.[581]

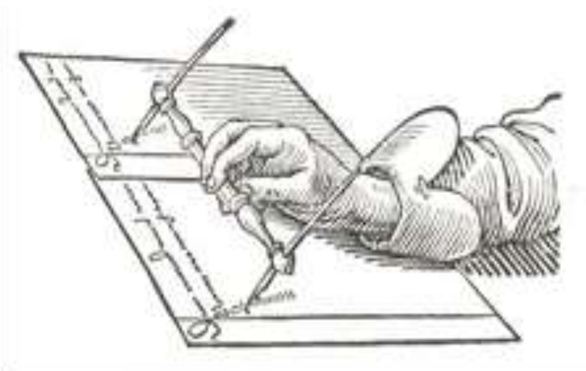

Figure 6-9: "Invention" for producing copies before the photocopier was available.[582]

6.3.3 Stična Books

Georg Philipp Harsdörffer (* 1. 11. 1607 Nürnberg; † 22. 9. 1658) mailed eleven Latin letters from Nuremberg to the Roman naturalist Kircher in 1653-1656.[583] Harsdörffer swore mainly on Francis Bacon;[584] he even imagined an airy belt around the hunter's hips, to make it easier for him to cross the waters with a gun on his shoulder and a newly caught bird.[585] After Porta and Ryffus' example, Harsdörffer described the siphon used to pump up water onto a hill, where he launched another pump.[586] He liked the description of the winds in Venice, which blasted in their time also to the fun of the Protestant Megiser of Carniola.[587]

In 1651 and 1653, Harsdörffer added the second and third volumes to Schwenter's Deliciae.[588] Cistercians in Stična acquired them. The Višnja Gora baron Maximilian Anton baron Taufferer bought Deliciae in the first edition of 1651, as well as in the second edition of 1677, and adorned them with his bookplates in 1720.

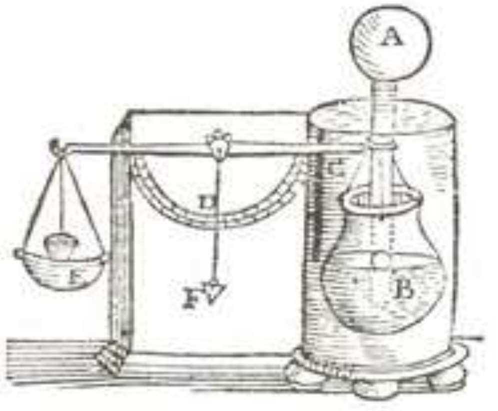
By **Johann Rudolph Glauber** (* 1604 Karlstadt; † 1668 Amsterdam) we call Glauber's salt, the sodium sulphate. Glauber was curious about many sciences. He spent his youth during the Thirty Years' War in Viennese cosmopolitan world, then traveled along the Rhine Valley, finally settling in Amsterdam for two decades, where he rebuilt a former alchemy house for modern vacuum and chemical experiments with burners and distillation devices. He became wealthy so he hired five or even six assistants, as he had a lot of income. Glauber's vacuum-related procedures and chemical ideas were sufficiently popular for the Cistercians in the Stična to buy as much as two of his books.



[589].

Figure 6-11 : A sketch of air weighing in the Stična library; first performed by Koper native Santorio Santorio (* 1561 Koper; † 1636) as an introduction to Torricelli's vacuum experiments.[590]

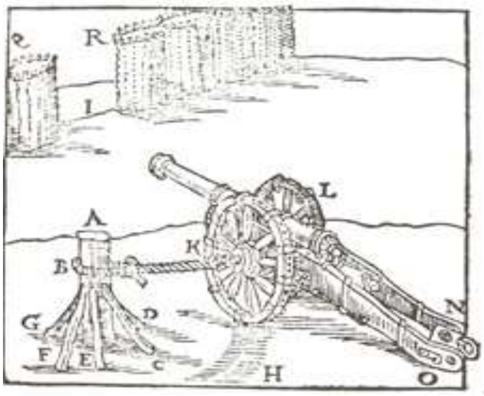


Figure 6-12: Fixed cannon to mitigate a recoil momentun.[591]

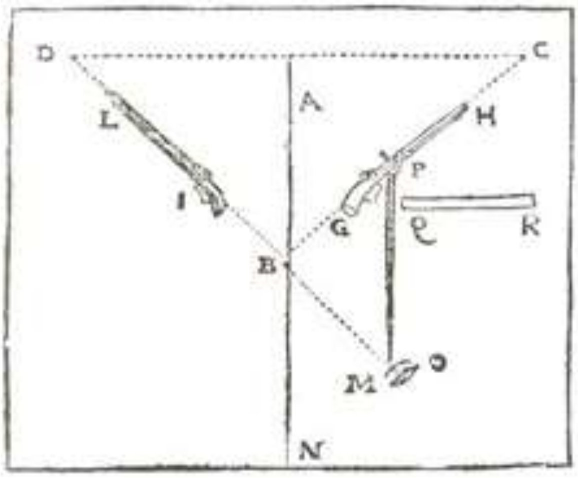

Figure 6-13: Target with a rifle in a mirror image.[592]

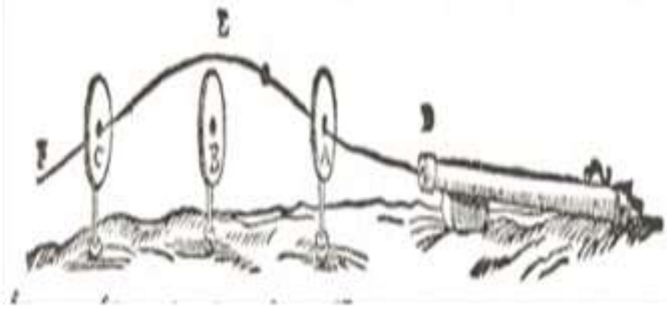

Figure 6-14: A sketch of the parabolic trajectory of a projectile in the former Stična Library.[593]

In the second volume, Harsdörffer described Marquess Guidobaldo Monte's moving images in perspective, Liceti's luminescence, and Mario Bettini's description of the burning with Archimedes' mirrors. He described Magni's and Kircher's experiments with a vacuum above the column of mercury, but he did not mention Guericke in this respect.[594] He was interested in a Girolamo Fracastoro's magnet supposedly useful for moving iron through the air despite W. Gilbert's criticism. Harsdörffer praised Heron's sphere with an overpressure as an ancestor of the steam engine and Bacon's description of the winds; he conscientiously illustrated concentric circles cut from paper for the correct formation of German sentences, the testing of the Drebbel's submarine on the Thames and Furttenbach's metal ship. After the ill-fated or maybe even useful habit of his days Harsdörffer ended his work with alchemy.[595]

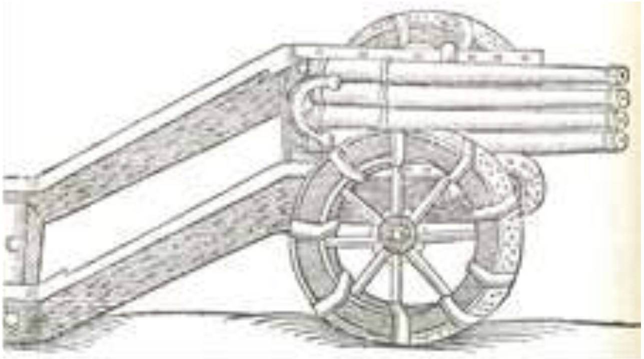

Figure 6-15: The cannon with four barrels which inspired the Cistercians in Stična.[596]

In his third book, Harsdörffer offered the reader a double feather for writing copies, Kircher's slightly missed Egyptian hieroglyphic research, Copernican Movement of the Earth, and the instructions of the Croat Marin Getdalić for weighing metals according to the provisions of the Archimedes' law.

Harsdörffer liked to play draughts (Checkers) or chess even with living figures: on the left he placed his female figures, and his right side was populated by male figures. The fortresses-castles, often referred to as elephants, were put in Spanish dresses, hunters were dressed in a Welsh costume, the farmers seeking for their transformations after reaching the end of the desk were courtiers or Garde-dames of the court.[597] Harsdörffer described the static of the sloping towers in Pisa and Bologna, the domestic Native American use of tobacco, and especially the drive of ships without sails or rudders,[598] which soon led to the invention of the steamer.

Harsdörffer described the old but still popular Torricellian experiment with a tube full of mercury tube, which he sealed with a finger and then turned clockwise quickly. Harsdörffer discussed Magni and Mersenne's experiments with Torricelli's vacuum, Pascal's barometric measurement of heights and the vacuum experiments of Kepler's Prague associate Benjamin Bramer.[599]

Harsdörffer offered many entertaining answers: How long do we live without eating dishes, Bacon's opinion on the use of salt, the afternoon's naps benefits… Harsdörffer provided thirty-four short, pleasant questions with answers suitable for evening social entertainment.[600]

The Cistercians in Stična did not avoid even using a vacuum in the military efforts at that time. Wolfgang Augustin Meyer (Mayr, Mayer) dated a preface to his military manual in Ulm on 8 January 1680. It was soon read by the Cistercians in Stična. The unusual book initially served thirty-eight figures - the pictures were followed by an initial chapter with descriptions of the tools.[601] Meyer then elaborated on the details of vacuum pumps and pumps with relatively complex seals and discharge openings conveniently adapted for pumping air out of the vessels. He added a description of big balls with water[602] and some smaller ones. He provided specific instructions on the preparation of the powder; he listed the masses of materials used with alchemistic signs for gunpowder, water, sulfur, turpentine, etc.[603] It was convenient for the reader to read the instructions and quantities needed for mixing, describing the best rockets and vacuum pumps; he knew how to check the quality of the gun and the fireballs popular in those times.[604] Loth was used to measure the mass, which weighted close to 13 grams.[605] The flammable substances were made from arsenic and sulfur. He summarized even the advanced artillery use of geometric devices, while he listed various useful types of firearms.[606] The second part of a book was compiled by Wurttemberg prince's engineer the captain Marx (Markus) Eysenkrämer von Bissigheim who resided in the house of the future apothecary in Besigheim 20 km north of Stuttgart in 1603-1634. For the instructive end Eysenkrämer listed ten rules of an expert artillerist,[607] trained in his dealings with a vacuum formed in a cannon tube.

Despite the rivalry between their orders, the Cistercians in Stična did not avoid even Jesuit writing about a vacuum: the desire for knowledge does not recognize secular restrictions. The Slovenian Jesuit Janez Baptist Cruxilia (Křižnič, * 23. 6. 1623 Tolmin; † 1684 Klagenfurt) began his book stored in a monastery in Stična with the

discussion of logic and continued with physics on 94 independently numbered pages. He devoted the third part to mathematical physics on fifty pages. He continued with physics-ethics on 38 pages and added the last part, metaphysics. He dedicated his work to Emperor Leopold I. The book was published in the form of a Philosophical and Physical Examination at the University of Graz, where he tested his Graz native student Gregor Sigfrid Count Dietrichstein without any sharp questions as the Dietrichstein family used to be one of the most powerful in all monarchy. Dietrichstein studied for his baccalaureate in philosophy. The conscientious student first considered Aristotle[608] in blind faith that nature opposes the installation of a vacuum; physics of empty space should be diabolical, but God is able to even work with it. He did not describe in detail the two decades old Torricellian experiment. The mathematical physics followed, and physics astronomy was next. The treatment was crowned by the technical physics, which Dietrichstein connected with the static of vacuum related tools and other machines.[609] At the end, he listed the questions from all Cruxillia's exam areas on unnumbered pages.

The Protestant descriptions of the vacuum were not unwelcomed to the Cistercians of Stična; so, they read Johannes Sperlette's (* 1661 Mouzon in Champagne; † 5 February 1725 Halle) book dedicated to Friderik III Brandenburg, the ruler of Prussia and the city of Magdeburg, where until recently the famous vacuum researcher Otto Guericke excelled as a mayor. Sperlette was a Huguenot which forced him to abandon France after the eviction of the edict of Nantes. In the time when he published his *Physica nova* he served as the rector and professor of philosophy in French Grammar school of Berlin. Sperlette was a gymnasium rector, the Doctor of philosophy and a public professor, according to today's terminology, a regular full professor. In the subheading, he listed mathematics with the explanation of the inevitable laws of motion. The real principles of the bodies followed and the description of the true nature of the vacuum.[610] In the title, he announced the images which he put in between the text; he drew a nice illustration of the law of refraction.[611] To his notes on Euclid he added a picture and illustrated Descartes' vortexes for the nice pictures.[612] In the second part of the book, he reported on the Zodiac, the »fixed« stars, gravity and lightness, as well as the rain.[613] To conclude, Sperlette served his questions from all physics: in Question 5, he exposed the supposed error of Epicurus and Gassendi. He refused any existence of the atoms with an intermediate vacuum included. He devoted the 42nd question to the local motions, and his 126th question to the Moon.[614]

The famous **Josip von Zanchi** (* 23 August 1710 Rijeka, † 1786 Gorizia) represented the new streams of Viennese students of Boerhaave's ideas in physics and philosophy. Zanchi was born in Rijeka in a patrician family. He entered the Jesuit novitiate in Vienna in 1725. He taught at the college in Gorizia and published a book with historical and scholastic content. In the years 1741-1752, he taught mathematics, logic, physics, metaphysics and ethics at the Viennese Theresianum and at the University of Vienna.

Among the popular Cistercian authors in Stična was Eusebius Amort (* 15 November 1692 Bibermuehle in Bavaria; 5 February 1775 Polling); a famous scholar, canon, professor of theology, and a librarian in Polling forty kilometers southwest from Munich. In third part of his work which he described physics, Amort narrated about the systems of ideas of physics, as the astronomy of Ptolemy, Tycho and Copernicus. Basically, he addressed Galileo's ideas in Torricellian vacuum experiments with a barometer[615] and a thermometer.[616] The last ninety-three pages of special physics Amort devoted to metaphysics, which sounded more like a pendant than anything like a special fourth part of a book. At the conclusion, he filled his first five tables with astronomical drawings. The sixth table dealt with barometer and vacuum techniques of his days, and the final three tables illustrated the biology of those times.

Figure 6-16: Zanchi's coat of arms.

The Cistercians of Stična read the textbooks of Zanchi,[617] who still did not accept the new Bošković's dynamic philosophy and physics; he based his explanation on Musschenbroek's Dutch version of Newton's physics, which was also very popular among the Jesuits in Ljubljana.

Zanchi restored Aristotle's science of matter and form in his double, metaphysical and physical sense. To his first book of "general physics" on three hundred eighty pages, he bound another book about the "special physics" with its own cover page and page numbering; both books eventually shared pictures. The first of these were interesting sketches of Magdeburg and other vacuum experiments, which stimulated the discussions already for centuries.

Zanchi divided his general physics into basic principles and observed types of bodies. In the second book, he described all three astronomical systems: Ptolemy, Copernicus, and Tycho's in the order of their origin. The role of water and fire in changing of the weather was followed. He came up with a special occurrence like the northern lights (Aurora Boreralis), along with modern metallurgy and even alchemy.[618] Then, in turn, he dealt with phenomena outside of mechanics: fire and cold,[619] elasticity,[620] and above all, magnets and electricity as unusual puzzles of those times.[621]

At the promotion of his baccalaureate candidate the Count Ivan Patačić von Zajezda he translated into Latin Noël Regnault's critic on Voltaire's Newtonian work.[622] The book was later reprinted four times as it promoted Cartesians from French nationalistic approaches.[623] It was purchased by the Cistercians in Stična, and at the same time by the Trieste and Ljubljana Jesuits.

The monks in Stična also bough books of their neighbor Jesuit (Franz Ksaver) Anton Erberg (October 21, 1695 Dol by Ljubljana; † 3. 10. 1746 Ljubljana), the first Carniolan writer of the modern textbook about physics. Up to his age of twenty-five Anton Erberg attended lower studies in Ljubljana, studied philosophy, entered the society of Jesuits, passed his novitiate, led the congregation, lectured in upper and lower secondary schools. He thus became acquainted with the Ljubljana higher school, which he later led. Between 1720 and 1723, he studied theology in Graz and at the same time took care of the library. After he took his three vows in Judenburg, he returned to Graz and taught ethics and then a three-year course of philosophy with physics from 1725 to 1728. Anton Erberg lectured again in Vienna between 1729 and 1731. He gave a three-year course in philosophy. From 8 December 1744 until his death he was a rector in Ljubljana. After his death his fans published his Logics, General and Special Physics, and repeatedly reprinted his Dialectical philosophy. He compiled those books already during his teaching of philosophy in Vienna and Graz between 1725 and 1735; he postponed the publication in anticipation of the Maria Therese's Reforms, which in the middle of the century imposed a new modern approach to physics teaching. He died already before the changes of natural science curriculum in Ljubljana and other Habsburg colleges.

Stična's monks were interested in siphons and similar natural vacuum-related hydrographic puzzles on their domestic karst: therefore, they bought numerous works of Jesuit Lecchi. In 1765, Jesuit Giovanni Antonio Lecchi (* 1702; † 1776) published Bošković's letter on the principles for the convenient rules for measuring the water flowing in the basins; he added the process of calculating the average velocity of a fluid.[624] Lecchi was the leading expert for Italian waters just like Grandi.[625] He was a professor of mathematics in the university of Pavia, where Bošković taught later. From 1738 until the ban of the Society in 1773, Lecchi taught at the Brera University in Milano, where Bošković taught afterwards. Then, Lecchi became a court mathematician and hydraulician of Maria Theresa with 300 florins of his annual salary as a kind of predecessor of navigational director G. Gruber. On the request of the Pope Clement XIII he managed river currents in the province of Emilia-Romagna until 1769. In 1752, Lecchi published a book on Newton's infinitesimal calculus; so, besides Bošković, Lecchi became one of the first researchers of new physics and mathematics among the Jesuits working in Italian areas. But already on 27. 5. 1766, Bošković found that Lecchi's book contained the "wrong assumptions" of his enemy, the Parisian academician d'Alembert.[626] In the beginning of 1774, in his letter to his pupil and associate Francesco Puccinelli (* 1741; † 1809), Bošković recommended Lecchi's work, but after Lecchi's death, he completely rejected him on October 25, 1780.[627] At the same time, Gabriel Gruber equally changed his opinion on Lecchi; the man resented him for his sharp assessment against the Ljubljana Canal. Gruber was the student of Bošković's friends, while Lecchi belonged to the different networks.

Anton's physics was published as the second and third part of his philosophy needed for the higher education, while his Institutiones dialecticae was intended for lower levels of instructions.[628] General physics was printed with Imperial privilege on November 4, 1750, and special experiments and vacuum techniques were issued next year. Immediately after that, the imperial decree of 1752 ordered the formal division of physics lectures into a general and special part. Thus, the textbook with the authority of the late rector Anton Erberg supported the introduction of of novelties into the study of physics.

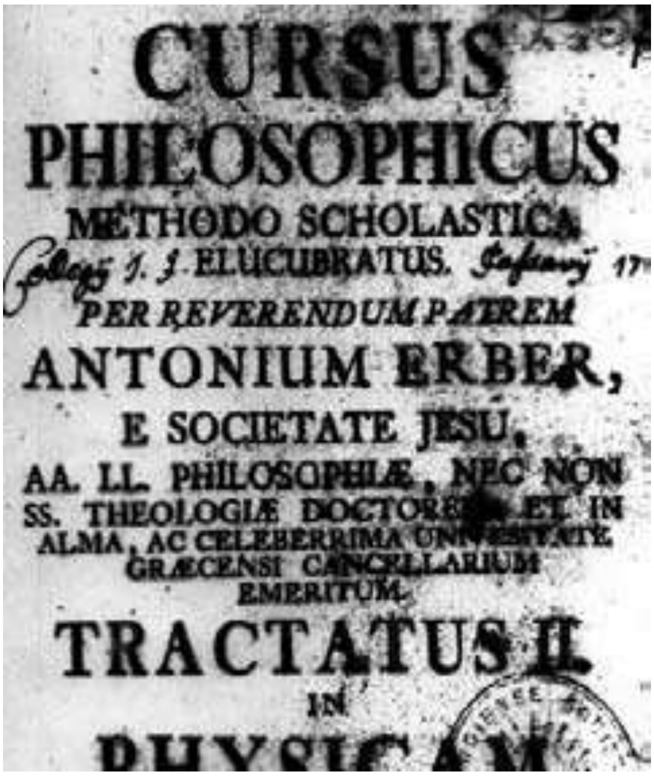

Figure 6-17: The title page of Erberg's General Physics (1750), the first book about physics of the Carniolan Jesuit scholar.

The monks from Stična lived in karst areas and were therefore very interested in Gruber's research, which "became productive" at his Ljubljana canal. In 1769 the Empress demanded a report on possible drainages of the Ljubljana moor. Gruber presented two proposals for the protection of Ljubljana from floods and the drying of the marsh at the invitation of the provincial Land Estates General in the same year. In the first he planned to deepen the Ljubljanica river for a very modest price of 74,271.42 guldens, while in the second one he was planned to spend somewhat more on canal, namely 82,744.17 guldens. The Gruber's canal was for only 10% more expensive, and Gruber supported that plan with all his might; of course, he cleverly presented the lowest possible costs in the hope that he would be able to increase them a little bit during the advanced course of his work.

Figure 6-18 : The cover of the book with Lecchi's criticisms of Gruber's ideas, which the Cistercians read in Stična.[629]

In 1770, a decree of the Viennese court ordered the creation of a special commission for the drainage of the Ljubljana moor. The members of the commission were the engineer Liber(ius) from the famous Ljubljana-based scholarly family, Gruber and the Milanese Jesuit Lecchi, who then resided in Ljubljana for a while. On the orders of the authorities, each of the three delegates communicated his opinion. In Milano, Lecchi received Gruber’s plans to build a canal; he disliked the proposal, which caused grave problems to Gruber. Lecchi felt that a deepening and widening of the Ljubljanica riverbed should be a better solution. Gruber criticized Fremaut's proposals, as well as "P. Lechi (sic!), Milanese Jesuit and known mathematician" and the ideas of engineer S. Hubert. Everyone advocated the deepening, while Lecchi even favored the extended the riverbed of the Ljubljanica river. However, their solution did not seem much cheaper than Gruber’s, and even houses near the Ljubljanica could be threatened, such as the home of Baron Zois on Breg. The most threatened would be the Jesuit college with its walls over the right bank of the Ljubljanica at the beginning of its current through the then city of Ljubljana. Therefore, the Jesuits of Ljubljana wanted the canal. Gruber proved to be able to provide the local high-society support because he used to be first home teacher of Žiga Zois, and was also supported by Žiga's father, the richest Carniolan Michelangelo Zois. While Gruber introduced Žiga to the mystery of the latest vacuum findings, Gruber told to both Žiga and his father about the threat of their palace on the Breg (side) of Ljubljanica river if, God forbid, the authorities would accept Lecchi's proposal.

Lecchi published his critique of the Gruber’s canal just before ban of the Jesuits on 23. 3. 1773, when the diggings of canal in white Ljubljana were already in full swing. By doing this, of course, Gruber's opponents were firmly supported, although at that time both Lecchi and Gruber were still the subjects to their Jesuitical order. Lecchi devoted his book to Francesco III[630] from the house of Este, the Duke of Modena, Reggio, Mirandola north of Modena, etc. Lecchi dedicated his posthumous work with the related topics to the archduke Ferdinand,[631] the 14th child of Maria Theresa, who was married to Francesco's granddaughter and his only heiress, Maria.[632] Thus, Lecchi dedicated both of his basic researches to the dukes of Este and their Modena, where he planned several highlighted meliorations of the local waters. Of course, the Cistercians in Stična used to read both books.

Lecchi divided his book into two parts, which he tied together. He independently paginated each part. In his second part, he first presented his work on two Italian waters in two dissertations. He devoted much of his book[633] to his vacuum-related hydrodynamic studies of the individual places of the German Empire in the years 1769, 1770 and 1771. In five sections he described his works in Šibenik of Dalmatia, on the Adige (Adiža) river in Trento, in Treviso, and by the Adriatic Sea in Ancona. He put his discussions about Ljubljanica river into the third section, which he sent to the Chancellor and Foreign Minister Kaunitz already on 27 February 1771. Lecchi referred to Gruber's

633 Lecchi, 1773, 79-195.

report and maps designed in the ratio of 1: 11300, so he did not even provide specific sketches of his own to his file. In three articles, he described the situation at that time near the Ljubljanica River, recommended improvements and his final decisions, which, despite some complimentary comments on Gruber, strongly opposed Gruber's intentions focused on canal. Lecchi used Gruber's measurements of the fall, width, tributaries, banks and floods of the Ljubljanica River. Lecchi began his description with a great deepening of the riverbed of Ljubljanica below the Jesuit school where Ljubljanica river enters the city of Ljubljana all the way to the house of Baron Codelli in the other side of then city; Codelli was an early friend and patron of Michelangelo Zois as both were native from Bergamo. Lecchi listed rapids and obstacles along the further flow of the traditionally sleepy river Ljubljanica. Lecchi considered the level of the riverbed, the depth of the stream and the influence of the bottom. From experience in Ferrara, Bologna and during the regulation of the Reno river that flows into the Po River, he has realized the unsteady variability of the rivers which flow in flat plains. In addition to technical notes, he also used pleasant thoughtful descriptions of the "nature of the waters in their free stream" and advised: "Do not go too far from natural circumstances ... let the river be where it was for centuries."[634] The Ljubljanica river with Barje (Moors) valley was treated as a lake in a satisfactory way, as a lake that can rise its level by source, rains, sand ditches, mills and other circumstances.

In 1769 the professors Breguin and Marcy,[636] as well as the cameral engineer Sigmund de Hubert (Hübert) assisted Lecchi in his measurements.[637] Lecchi estimated the volume of material that should be removed at the beginning of the Ljubljanica river and from its riverbed in the city itself; he intended to increase the speed of the river, so that during the spring floods the water level would not have risen for more than four feet. What obstacles does one had to overcome to achieve the desired flow rate? In the discussion, he expressed the opinion of Professor Gruber, although Lecchi felt that all data on the river flow was not available. Also, the complete destruction of the Ljubljana mansions storage facilities and mills because of the deepening of Ljubljanica and floods did not bother Lecchi much; in Lecchi's opinion, Gruber was supposed to spend the unknown higher costs for his canal. For this reason, he proposed the use of locks, as they had already done on Italian rivers. This, of course, was much cheaper, as instead of part of the human hands or very rare useful manufactured devices before the emerging vacuum technique of steam and mechanical machines, they could use the power of the river stream. The flow was supposed to deepen its own riverbed by itself in two or three years. A similar procedure, where the river itself was friendly digging its own bottom, Lecchi had previously tested for his drying works near Bologna; of course, the excavated bottom should be maintained every year. After the second year of work, the river should dig its own riverbed for two feet unaided, while in the third and fourth year it will dig up for two additional feet. New depths would contribute to the permanence of the riverbed. However, the deepening of the Ljubljanica River would make the work of the mills impossible at the end of the city because the mills will remain to high above the water of river. Lecchi was sorry for them, "but such was the price of general well-being," he commented sarcastically.

MEMORIA TERZA

Figure 6-19: Lecchi on the Ljubljana Canal with a critique of Gruber's ideas, read by the Cistercians in Stična.[635]

[634] Lecchi, 1773, 152-173. Prince Wenzel Anton count Kaunitz-Rietberg (* 2. 2. 1711; † 27. 6. 1794).

[635] Lecchi, 1773, 152.

Lecchi had some concerns, he did not look at Ljubljana's circumstances in detail but summed up his data mostly by Hubert's notes. Concerning the drainage, he referred to Gruber's sketches[636] and considered the underground tributaries of the Ljubljanica River. He advocated the preservation of old bridges and encouraged the installation of new ones; in any case, it was all still relatively cheaper than the canal.

In conclusion, Lecchi criticized the Gruber's Canal project, although he repeatedly referred to Gruber's sketch. The canal was projected in the middle between the two hills behind Codelli's house-castle; of course, the canal would take most of the waters from the original riverbed and increase its speed. However, after many years of experience, Lecchi supposed that without any obvious urgency it is not necessary to deal with such a costly and radical intervention. According to Lecchi, the Ljubljanica already has a sufficiently large force at the Old Caves (Stare Jame) near the mill, where Gradaščica spills in, and the new canal overflow would, of course, reduce the force of water in the Ljubljanica river. The redirection of parts of water into the canal would have shared some of the water that was available for the millings so far. According to Lecchi and by Galileo's student Castelli,[637] the amount of water transferred is proportional to its speed,[638] which of course is a very simplified D. Bernoulli's theorem. Such a stream would not by itself eliminate the threatening floods, as it would only work at relatively low water levels. In addition, the tributaries of the Ljubljanica River bring a lot of material; they can even overfill a canal and prevent rotation of the mills.

Therefore, Lecchi cleverly described the canal as a peculiar risk and led the water to his own mill focused on deepening the riverbed. Finally, Lecchi added some glimmering hints about the private interests of people involved in planning the Ljubljana canal,[639] which, of course, interfered with the very core of the problem focussed between the golden yellow crowns. Lecchi did not expose Codelli and Zois with their names, but all readers knew what was Lecchi talking about. Lecchi's deepening and expansion of the Ljubljanica riverbed would never spend so much money as the Gruber's canal, which at that time became one of the largest projects in the entire Habsburg monarchy.

On the other hand, Gruber presented his canal with flows, falls, and underground vacuums while using the support of major Struppi[640] and Hubert.[641] Baron Zois and a lot of other Carniolan wealthiest folks were supporting Gruber; so, on March 9, 1771, ten days after Lecchi's report to Kaunitz, the Viennese authorities decided to prepare the money and give Gruber a green light. Lecchi's luck began to fade, and soon after him Kaunitz's star was in decline, while Gruber's reputation grew steeply. Lecchi died at a time when Gruber was still working on a canal; in the posthumous issue of his works on the waterways in 1776, he no longer mentioned the dispute around the Ljubljanica River, but rather concentrated on the waterways in the areas of Milano, Modena, Reggio and Venice.[642]

6.3.4 Conclusion

For centuries, the Stična Cistercians built their base of learning in Lower Carniola (Dolenjska), and they also intervened in the field of technique and vacuum devices closely related to the regulation of karst waters in their immediate Ljubljana neighborhood. In the early days, they accepted the correct interpretations of early vacuum experiments, especially from the books inherited by Florjančič. Unfortunately, half of a decade after Florjančič's death, the monastery in Stična was recklessly abolished and many of the literary treasures were forever lost on their way from Stična to the white Ljubljana or to the Viennese metropolis.

6.4 Capuchin and Franciscan Vacuum in the Middle of the 17th Century

6.4.1 The First 800 Years of Franciscan Vacuum for Slovenes

6.4.1.1 Introduction

The Friars Minor Franciscans with St. Francis' guide to the collection of scriptures in honorable places strongly influenced the development of libraries among Slovenes and, basically, the reading of natural science books related to vacuum research. They were and still are the most numerous religious order in Slovenia. In Slovenian country, they established themselves in all three branches: Franciscan Friars Minor Observants, Friars Minor Conventuals (Minorite) and Capuchins. Many Slovenian scholars were studying with Franciscans and often joined their monastic order. Who were the Franciscan vacuumists on the southern slopes of the Alps?

6.4.1.2 Vacuum in Kamnik

In the monastery in Kamnik the Franciscans led the elementary school, later even the secondary Latin school-gymnasium transferred from Kostanjevica above Gorizia to Kamnik. In their Kamnik library, the Franciscans kept the medicine of the famous Helmont. Perhaps it was the son of the famous "erudite" Janez Vajkard, the Kamnik guardian Donatus Valvasor, who was interested in exploring the vacuum as he learned a lot about it in his father's library at Bogenšperk?

After his group portrait with his son (and publisher), Francis Mercurius van Helmont, J. Helmont dedicated to his son his own medical and chemical work at the end of the Thirty Years' War. He described four ancient elements, and especially the gas and nature of the vacuum with criticism of Aristotle included.[643] He did not know Torricelli's experiment, since he designed it in the year of J. Helmont's death. Helmont described the magnetic force[644] and especially Paracelsus; the son-publisher added many amazing stories about the effectiveness of the philosophical stone,[645] for which Father Helmont certainly would not put his hands in the fire. The ancient theory of four elements was still a part of science as the Ljubljana bookkeeper Mayr sold data about it in the astronomer Trigler's[646] and many other books which even the Franciscans of Ljubljana bought for their library.

The provincial Governor Volf Engelbert naturally did not want to be left behind the Franciscans of Kamnik. Therefore, he bought the same Helmont's work for his library in Ljubljana in a slightly older edition. He collected several hundred pages of Helmont's previously unpublished criticisms of Galen's advocates, the descriptions of fire, illnesses

and, above all, plague in four specially paginated works.

According to the Franciscan Kamnik monastery catalog from 1760, medicine with surgery, anatomy and botany was included into twelfth expert group, while the philosophy with mathematics, meteorology and arithmetic belonged to the tenth expert group. Both groups also included vacuum books. Among the medical books were the works of authors like Levinus Lemnius, the Jesuit vacuum researcher Gaspar Schott and Stahl; Newton's Optics with the addition of his papers published in Phil.Trans. were bought in a Latin Clarke’s translation issued by the Graz Jesuits.[647] Typically, in addition to the Erberg Barons in the Slovene area, only the Franciscans of Kamnik and Novo Mesto (New City) enthusiastically bought Newton's works with modern conceptions of atoms and intermediate vacuum, as only those Franciscans taught to their students the physics doctrines at sufficiently higher level.

6.4.1.3 The Vacuum-related Books among the Škofja Loka Philosophical and Physical Writings

The Upper Carniola Capuchins first settled in Kranj (1640) and only on 28 April 1707 in Škofja Loka; however, after the abolition of the Kranj monastery (1786), the books of Kranj Capuchins were transferred in their neighboring Škofja Loka Capuchins’ headquarters[648] together with the individual writings of the Novo Mesto (New City) Capuchins.[649]

The Škofja Loka Capuchins loved to read the old good Albertus Magnus; they especially preferred his mineralogy, but less his physics or astronomy.[650] Albertus' biography was obtained from Trithemius’ Benedictine Pen as an introduction to Albert's mineralogy with botany, which is also preserved today in NUK in two pocket editions without bookplates.

The courageous Škofja Loka Capuchins did not refuse Protestant books if they only helped to clarify the mysterious properties of vacuum. They stored a book of Wroclaw Lutheran Daniel Sennert, a professor of medicine in Wittenberg (1603), where he taught together with his brother-in-law Michael Döring. Sennert combined the obsolete Galen's medicine and Aristotle's doctrine with the criticism of Paracelsus's novelties in his promoting of the advancement of atomism; it became the mainstay of Boyle's thinking about the vacuum.[651] Volf Engelbert Auersperg obtained two Sennert's books, and in May 1678 Mayr offered to his Ljubljana clients in addition to two Sennert works also the Jakob Barner's (1641-1709) book on Sennert's medical systems. Barner taught medicine and chemistry in Padua and Leipzig. In Ljubljana, they stored two reprints of Sennert's medical letters (1634), which were also purchased by Volf Engelbert Auersperg. In one of his books offered in Ljubljana, Sennert's discussion of heat was bound to Sennert's Letters; in the second reprint, however, no such binding took place. The Škofja Loka Capuchins acquired the earlier publication of Sennert from the year 1611. Sennert described nature, as well as the branches of medical sciences.[652]

The Škofja Loka Capuchins loved to read the books of writers from their otherwise opposite Jesuit order; they bought a book of Jesuit Schott, who first described Guericke's vacuum experiments while using Guericke's pump. In the Škofja Loka Monastery they read a philosophical course with physics of Capuchin of the Swiss province, Gervais Brisacensis. After his logic, Gervais also dealt with general physics with a special emphasis on vacuum experiments with the mercury barometer of Capuchin Valeriano Magni. He apparently attributed to his colleague Magni even the Torricellian experiment, as he did not even mention the poor Torricelli.[653]

6.4.1.4 Books on Vacuum Classified as Medical Science in Škofja Loka Capuchin’s Library

In 1717 the Škofja Loka Capuchins acquired the reports on Lower’s research in London. As the first, Lower introduced blood transfusions among the Westerners; he collaborated with Robert Hooke, the manufacturer of Boyle’s Vacuum Pumps. The Škofja Loka Capuchins also read Paracelsus and the predecessor of Stahl's theory of phlogiston combustion, Becher. Latter, Becher became a commercial councilor in Vienna in 1666, which heightened the popularity of his work in Habsburg Monarchy.

6.4.1.5 Franciscans for Ljubljana Jesuits: North Italian Brixianus and his Local Critic Markilič

The examples of Capuchin vacuum researcher Magni were soon followed by researchers from other branches of the Franciscan Order. The experimental textbook about physics of the Friar Minor Conventual (Minorite) monk from Brescia (Brixianus) was acquired by the Ljubljana Augustinians. B.F. Erberg (1751) bought Brixianus’s mathematical textbook in four parts (1738, 1739) including his presentations of surfaces of revolution for the Jesuit library of Ljubljana as one of the manuals needed for updating the instruction according to the instructions of the emperor Empress Maria Theresa. The Franciscans of Novo Mesto (New City) had both parts of their Friar Minor Conventual (Minorite) co-brother Brixianus’ book, the physical part even in two different editions according to the old good Lower Carniola (Dolenjska) principle of the "similar supports the similar".

The Friar Minor Conventual (Minorite) Fortunatus Brixianus (Brixia, Brixanus, Girolamo Ferrari, *1701 Brescia; 1718 OFMConv Borno by Brescia; † 1754 Madrid) was a professor of natural science with mathematics in his native city of Brescia, after which he assumed his own pen name. In 1738 and 1748 he was in Venezia and Padua and in 1744 and 1750 he was in Rome where he picked up some influences of the Jesuit G.B. Tolomei. However, the progressive acquisition of Newtonian physics did not make Fortunatus Brixianus a true epistemological follower of his model; while he was abandoning the Cartesian physics during his travels, he never abandoned the strict mechanistic assumptions, so he always refused to consider the “accurate measurements supporting of Newtonian formulas as evidence of the physical reality of universal gravitational attraction”, which deprived Fortunatus Brixianus of Bošković’s eventual support. Fortunatus Brixianus even developed some aspects of history of mathematics from the ideas of Ramus’ Historia Mathematica, and the books of the Jesuits Millet de Chales (Dechales), Aimé Varcin (1630-1702) as well as the famous Ch. Wolff. In 1753 Fortunatus Brixianus became a secretary of the general of Franciscan order Pedro Juanete de Molina (1698 Onil in the Spanish province of Alicante south of Valencia-1775 Vila-Real in Northern Portugal) who soon departed from Rome to Madrid.

Fortunatus Brixianus advocated the modernized slightly Newtonian ideas of the Franciscan Duns Scotus, atomism, and strict adherence to mechanics as the foundation of natural science. In the experimental and mathematical textbook, he did not recognize the scientific authority of the church or Aristotle, and the validity of the Brixianus textbook about physics was confirmed by scholars in Venetian academic center of Padua on 20 September 1745. The Augustinians of Ljubljana used the edition of Fortunatus Brixianus’s work published in 1751 and 1752; it consisted of two books on general and one on special physics especially focused on astronomy with chronology. Later, those books were given to the Ljubljana Lyceum library, where part of the leaves remained uncut until the end of the 1990s. It seems that Brixianus did not have any special readers among Ljubljana's Augustinians? Two and a half century after its printing the writer of these lines took over that unread book in NUK, as it had apparently not caused excessive interest in the white capital of Ljubljana.

Brixianus has addressed many contemporary researchers, including Gassendi with his vacuum in the pores[655] connected with Du Hamel’s preservation of vacuum, and the Cartesian Le Grand with his Institutio Philosophiae which also belonged to Ljubljana Franciscan library and to Valvasor’s library as it was on sale in Mayr’s office in Ljubljana. In his book *De Meteoris* Jean

[655] Brixianus, 1751, 1: 52.

Baptiste du Hamel has tried to combine Scholastic approach with Descartes's innovations.[656] Brixanus noted his neighbor Jesuit Lana Terzi of Brescia,[657] 'sGravesande, Musschenbroek[658] and Boerhaave. Two Le Grand's published supports of Descartes were put on the Papal index together with several Descartes' books. Le Grand favored the intermediate direct contact of bodies and used Descartes' example of emptied glass to refute the vacuum. Le Grand highlighted the remains of the water in an empty jar so he could deny the vacuum.[659] Le Grand noted the pneumatic experiments, mostly those of Gassendi with the salt in allegedly differently shaped atoms, and the experiments with the Aeolian Harp.[660] Le Grand used Gassendi's explanation of Torricellian experiments of barometer with the notes on the evident translation of heat and light in the vacuum.[661]

Brixianus researched natural phenomena with experiments without specifically considering Aristotle's opinion or theologians.[662] He did not describe Torricelli's experiments[663] in a large section on the vacuum, although he acknowledged the existence of a vacuum and endorsed a tremendous amount of evidence from Torricelli's Florentine Accademia del Cimento to distinguish between heat and cold-producing substances.[664] Among the Newton's critics, he quoted the Italian Venetian translation of Lezioni di Fisica (1743). The author was an honorary member of the Parisian Academy (1721) and a member of the London Royal Society (1729) Joseph Privat de Molières (1734-1739).[665] Molières based his book on his own lectures at Royal College and tried to mix Newtonian theory with small Cartesian vortices of Malebranche.

At the end of the first of his books about general physics, Brixianus recommended the Newton's Principles in the edition of Roman Friars Minims Bošković's later collaborators Thomæ Le Seur (Leseur, B. 1703 Rethel; OM; D. 1770 Rome) and Francisco Jacquier (B. 1711 Vitry-le-François; OM; D. 1788 Rome) published in 1739, Samuel Clarke's Newtonian optics also available in the library of Franciscans in Novo Mesto (1741), Musschenbroek's translation of the reports of experiments of Accademia del Cimento (1731), the Venetian edition of Boerhaave's Chemistry (1737) and some medical writings. The recommendation fell to the fertile ground, as the Franciscans of Novo Mesto (New City) besides Brixianus, obtained an edition of Friars Minims of Newton's Principles and one of Musschenbroek's works. Likewise, the Franciscans of Ljubljana read Musschenbroek's books and Jacquier's textbook with its 3rd - 6th parts focused on mathematics, general physics, experimental physics and ethics. By funny coincidence the Friars Minor Conventual of Ptuj obtained from their religious co-brothers of Graz the first two parts of Jacquier's textbook about logics and metaphysics in Graz edition which the Ljubljana Franciscans missed in Jacquier's textbook published in Venetia by Simon Occhi in 1762 .[666]

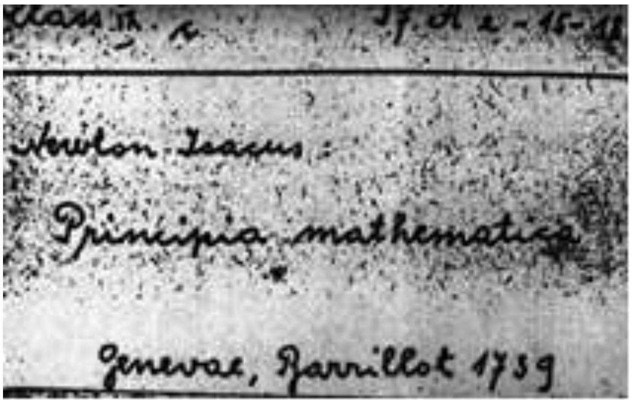

Figure 6-21: Toš's catalog of Newton's Principles (1739) in the Novo Mesto (New City) Library Catalog of 1942.

Brixianus began his first book with formations-creations of the bodies and appearances of bodies according to natural principles; Brixianus divided his second book into chapters on the source of gravity,[667] artificial and natural gravitational movement,[668] and especially the gravitational movement of fluids with a special emphasis on hydrostatics.[669] Brixianus devoted the penultimate

chapter of his second book to the suspension of mercury in Torricellian pipes. He described Boyle's criticism of the Jesuit Francis Linus (Hall), before explaining Musschenbroek and Pascal's experiments. He was also aware of the merits of Huygens, of Newton's assistant Samuel Clarke and of a Minim (Paulanerorden) monk Emmanuel Maignan.[670] Brixianus compared the measurements of the densities of air of dozen researchers in Musschenbroek's tabled commentary of Florentine academic merits.[671] Brixianus finished his second book with sketches of motion, slopes, collisions, communicating vessels, vacuum barometers and thermometers.

Figure 6-22: Le Grand's (1679) painting on the title page of his book in Franciscan Library of Ljubljana (noted as F).

Brixianus divided the last third book of special physics into six dissertations about the creation of the world, the mathematical description of the Earth, the system of the universe, the special useful features of stars and chronology. He published two copperplates of the Copernican system separated by the copperplate of Tycho's universe;[672] the obsolete Ptolemaic doctrine has been obviously already turned away into the old nonsense. With the last nineteenth group of images, he explained the solar eclipse. He used Newtonian teachings in both mechanics and optics.[673]

The curator of the library of the Franciscans and several times guardian Hieronim Markilič (* 1712; OFMobs; † 24. 5. 1790 Ljubljana) was among the fiercest sharpest critics of his own elder religious co-brother Fortunatus Brixianus (a Brixia, Brixanus, Girolamo Ferrari, * 1701 Brescia; OFMobs; † 1754) and other modern researchers.[674] In 1764 in Ljubljana, Markilič acquired eleven years old Scholastic Regensburg Philosophy of Benedictine from Prüfening Abbey (Prifling) monastery on the outskirts of Regensburg in Bavaria Veremundus Gufl (* 1705; OSB; † 1761) with a detailed description and sketch of Pascal's experiment[675] and Schott's explanation of work of Guericke's pumps.[676] Gufl made dozens of experiments. In 1769 the Franciscan H. Markilich (Markilič) rejected his assumptions together with the opinions of Fortunatus Brixianus (of Brescia).[677]

624 Pars Tertia.

condi elementi globulorum ... quuntur; iisdem autem ... extrusis, ad se invicem accedere coguntur, quæ veluti capillamenta se impediunt, obstantque, ne solitis motibus circumvolvi queant. Quare à materia subtilissima lacessita, suis extremitatibus se mutuò verberant, & à loco dispellunt: Unde ita vires suas intendunt, ut majus spatium occupare nitendo, Aquas sursum versus jaculantur, & eas vi magna emittunt.

Eadem prorsus ratione ...

In 1777, Markilič used the 18-year-old Zagreb-based tract of imprecision of philosophy, published by the professor of physics in Ljubljana, Jožef Matija Engstler. It was translated by Kazimir Bedeković. Bedeković translated into Latin the Reflections upon learning of Thomas Baker which was published anonymously in 1709/10 and posthumously in London in 1756. At the same time the translation was also published in Zagreb bound with their local examining thesis by the same printer Härl. Bedeković was born near Varaždin and studied philosophy in Vienna in 1758. He taught physics in Zagreb.[678] Baker's ideas enabled numerous translations by which many thinkers profited, including Engstler and Bedeković: they initially published only one page of the unpaged welcome introduction. Baker devoted his seventh and eighth chapters to physics and astronomy.[679]

Figure 6-24: Le Grand's sketch of Descartes vortexes around a magnet in Franciscan Library of Ljubljana (Le Grand, 1679, 599); F.

The Englishman Baker criticized Descartes and defended the modern theory of vacuum and molecules advanced by the Minim monk Mersenne and the Jesuitical classicist literary critic and opponent of Jansenism René Rapin's (1612-1687) *Reflexions sur la Poétique d'Aristotle*. Baker also supported the Parisian Jesuit superior Gabriel Daniel (1649-1728) who criticized Descartes's vortices in 1690 and additionally refused Pascal's Jansenism four years later.[680] In fact, Baker was

6.4.2 Franciscans for Ljubljana Jesuits: North Italian Pace

Despite the long-standing disputes, Ljubljana Franciscans read many Jesuit books and the Jesuits in Ljubljana read many of the Franciscan writers. Among the most popular on both warring sites was Franciscan Stefano Pace with his Italian written Physics of Peripatetics, Cartesians and Atomists. In his own way, he was in love with the two groups of monks, as he was the Jesuit in Parma until God's caution seduced him in Franciscan habit. In the first two parts of Pace’s work, the Jesuits of Ljubljana entered their bookplate in 1771, thirty years after the printing of that book; during this time, the Franciscan poet and teacher Valentin Vodnik almost certainly learned about Pace's ideas.

Pace was initially the Jesuit in Parma, but in 1697 he joined Franciscan order. He borrowed up his physics’ ideas from the Jesuit Paul Casati, but Pace used to teach philosophy more than mathematics.[682] Pace described the individual phenomena (light, frost, heat, electricity) in a series of events, and he quoted Cartesians, atomists, old scholastics, and new peripatetic; among the latter, he most likely considered himself, since he always cited the peripatetic beliefs as the last. Pace began his first part with a praise of Roemer's measurement of the speed of light as the achievement of the "second Tycho", probably because both were Danes.[683] Pace noted the description of the Glauber’s[684] cold and salt, the air pressure with a vacuum and Torricellian

experiment.[685] Pace continued with Boyle's achievements,[686] the Bologna stone,[687] and the description of Cartesian assumptions of Jacques Rohault (* 1620; † 1675).[688] Pace mentioned Gassendi,[689] but not Newton. Pace's 18th Chapter of Tractate II of the first part discussed the vacuum experiments while in his last 19th chapter Pace narrated on the movement in the empty.[690] He quoted Aristotle and his peripatetic fans,[691] and also Pace's neighbor, the Jesuit Lana Terci. The first part was completed with Pace's sketches of reflection and refraction of light, hydraulic paradox and vacuum experiments, even the famous Huygens' experiment of vacuum in vacuum, which Pace ascribed to Gilles de Roberval (* 1602; d. 1675).[692] Pace dedicated his last book to biological sciences.

In the six tracts of the second book, Pace described the substance in stars,[693] comets,[694] astrology for decision-making,[695] individual planets,[696] tides,[697] transformations of metals,[698] and finally underground waters and earthquakes.[699] The images inserted at the end of the text presented all the possible systems of the world, the eclipses, the refraction of light and magnets.

6.4.3 *Franciscan Library in Novo Mesto*

The Novo Mesto Franciscans also used Jesuits' works as well as the books of Augustinians. Among most important Novo Mesto works from Augustinian networks was the book of the son of a Bavarian shoemaker Maximus von Imhof (* 1758: † 1817), who taught mathematics and philosophy between 1786-1791 at the Munich Monastic School. In 1790, he became a member and ten years later the director of the physical class of the Munich Academy. In 1790 he was a professor of physics and mathematics in the prince-elector's Lyceum. For two decades, he led the installation of lightning rods in Bavaria and described them in several books, which made his work likewise important as the achievements of Biwald, Ambschell or Giuseppe Toaldo's (1719-1797) introductions of Central European lightning rods networks south of Imhof's Bavaria.

The Augustinian monk Maximus Imhof was a full-time professor of physics, mathematics and economics in the Munich lyceum, as stated in his Latin textbook Institution physicae (1797). He cited Boyle and Hauksbee's vacuum experiments[700] considering both the attractive force and the repulsive forces.[701] He reported in detail about Lavoisier's and Crawford's theory of combustion against phlogiston with the discovery of phosphorus included;[702] as well as the dispute over the electricity of Nollet and Symmer against Franklin.[703] Despite of his notes about Franklin, 'sGravesande and Musschenbroek, Imhof avoided any mention of Bošković.

Zinsmeister liked the pioneer of the Bavarian lighting rods Maximus von Imhof who was probably Zinsmeister's teacher besides Hiebel when Imhof replaced Epp as the full professor of physics, mathematics, and economy in Munich Lyceum after the year 1790. It is very likely that Zinsmeister himself brought the textbook of his Bavarian compatriot Imhof to the Novo Mesto Franciscans' Library. Imhof was among the rare authors whom Zinsmeister cited in his manuscript, although just in the later additions in the margins of his work. Zinsmeister admired Imhof's explanation of the impenetrability of matter which caused the reflection of light. Imhof certainly discussed vacuum experiments considering the attractive and repulsive forces,[704] but he didn't mention Bošković.

Indeed, even the Novo Mesto Franciscans followed the phlogiston fan Stahl's ideas that prevailed until Lavoisier's days; so, the Novo Mesto (New Town) Franciscans bought at least four Stahl's books and

stored three of them in the shelves with medical works.[708] The inventor of the phlogiston theory, Georg Ernest Stahl of Jena, excelled himself as a chemist, doctor and university professor in Halle until he became a court physician and a councilor of the Prussian king; Zois also readily used his own collection of Stahl's books. Novo Mesto Franciscans bought all Boyle's discussions of vacuum and other works, like Valvasor in the nearby Bogenšperk; so, all versions of Boyle's vacuum pump were well looked after. They also obtained the assumptions of experimental physics of Boyle's correspondent Placentini, called Tarvisini, as well as Boyle's correspondent from the Kiel and Altdorf universities, Günter Christophe Schelhammer. Placentini rejected Schelhammer's assumptions about the vacuum in the barometer and preferred Leibniz's ideas. Even in the late Baroque, the Franciscans of Novo Mesto (New City) taught according to Leibniz's guidelines, because they purchased many Wolff and Sturm's works with the adaptations of the Augustinian monk Desing included.

Novo Mesto Franciscan entered their Newtonian era to end the Cartesian influences against the vacuum by the intervention of Englishman Keill.[709] Keill studied under supervision of the professor David Gregory in Edinburgh, who immediately after the printing of Newton's Principles began to teach about them. Keill accompanied Gregory even to Oxford when Gregory became a professor of astronomy there in 1702. Keill soon acquired himself a chair of professor of philosophy and was among the first to lecture on Newton's natural sciences. He taught the freemason John Désaguliers, whose experimental manual was purchased by the Jesuits of Ljubljana in 1754. Keill proved Huygens' Theorem on centrifugal and circular motion.

A Novo Mesto (New City) edition of Keill's textbook was published simultaneously with the Minimite (Minims) Friars' adaptation of Newton's Principles. Both books were urgently needed by the Franciscans of Novo Mesto (New City) at the beginning of their higher education lectures under the orders of Maria Theresa and van Swieten. Van Swieten's compatriot, the Dutch Newtonian advocate Musschenbroek, was not only popular among the Novo Mesto (New City) Franciscans, but also with the Jesuits of Ljubljana. In 1754 the Jesuits of Ljubljana bought Musschenbroek's book in a half of decade old French translation, while the Franciscans of Novo Mesto (New City) preferred a later edition of the Latin originals. Shortly after Musschenbroek's death, five other Musschenbroek's publications were listed in F. Wilde's catalogue among Ljubljana Lyceum works in a total of six Musschenbroek's books. Except for *Essai*, all of them were published in Latin language. Two books were printed in the Netherlands and Vienna, and one even in Ljubljana by B.F. Erberg and his students. All works were printed in the Quarto Format between the years 1739-1768 (1739, 1753, 1754, 1754, 1761 and 1768). Four of them had a general, emphasized

[708] D. Mušič, From the history of medicine, in: *Medical examiner* (1938), 445.
[709] Keill, 1742, 196-208.

experimental character with vacuum experiments: one dealt with magnetism and the other focused the familiar but awesome capillarity.

The Franciscans of the Novo Mesto liked to read the writings of former professors of Ljubljana including Biwald, Ambschell or Neumann, who advocated Bošković's description of the vacuum. Of course, those were mainly the schoolbooks, which were recommended by the Viennese authorities.

More than a textbook of benevolent but less learned Kersnik, the influence of the Ljubljana Jewish mathematician Gunz spread across all Carniola. The mathematical textbook of his father Simon Gunz (Guntzhausen, * 1743 Augsburg; † 11. 11. 1824 Prague) became the basis of instruction even in Novo mesto, where the fans of French Napoleonic occupation did not completely renounce the Franciscan help. The Franciscans of Novo Mesto taught their young monks, among them Vodnik, in two years of philosophical studies. After the break during the Josephine reforms, until the March Revolution (1848), they again educated their pupils in two philosophical years; they did not want to accept laymen in Franciscan philosophical course because the townspeople of Novo Mesto did not want to contribute money to cover part of the costs.[710]

6.4.4 Vacuum Devices of Bernard Vovk in Novo Mesto

The Franciscan Bernard Vovk was a longtime professor of physics, meteorologist and gymnasium (Grammar School) headteacher in Novo mesto. Among his talented students was a famous researcher of the speed of electromagnetic waves in a vacuum Ignac Klemenčič, professor in Graz and Innsbruck. With the help of the most modern barely a decade old Geissler's Bonn vacuum tubes, Vovk learned all about the mysteries of the expansion of waves in a vacuum very early. With his purchase of Geissler's vacuum cathode ray tubes, Vovk showed to his students the best vacuum at that time only a couple of years after the Grammar School in Ljubljana acquired similar devices. Of course, the vacuum devices were not among the cheapest tools, so the canon Josef Žagar was very helpful to professor Vovk. For Žagar's 1 fl öw it was possible to buy a kilo of beef at that time. Thus, for the price of the Geissler's electrical glow discharges in diluted gases leading to the cathode ray tubes, Slovenian ancestors could already afford a pleasant feast for well-padded tables, which would be submerged under the weight of delicious roasts.

6.5 Vacuum of Franciscans in Ljubljana

6.5.1 Introduction

The Franciscans of Ljubljana have been a decoration of their home city for eight centuries; first on the premises of the now heavily used food market, and later for more than two hundred years on the other side of the Ljubljanica river, on the square of St. Mary, which was later renamed to the poetical saint France Prešeren. After many years of efforts, however, the writer of the present lines succeeded in inspecting the foundations of books stored there and thus he penetrated in the spirit of the former Franciscan design. What was the Franciscan opinion about early vacuum techniques given that the first Carniolan vacuumist Prince Janez Vajkard Turjaški (Auersperg) was buried right on the premises of the former Franciscan monastery on Vodnikov trg, and the ashes of his bones could soon serve to decorate the new Ljubljana subterranean garages?

6.5.2 Škerpin's Merits

The scientific efforts of Jesuits were the hot topics of the past decades in history of science. The Franciscans and Minims were always their match, to mention only Marin Mersenne (* 1588; OM 1611; † 1648). Therefore, the Franciscan and Minims' scientists of the past centuries also deserve some glory; it is high time to reverse the

[710] Vrhovec, 1891, 269.

roles and to give the Franciscan scientists of the past centuries the fame they deserve.

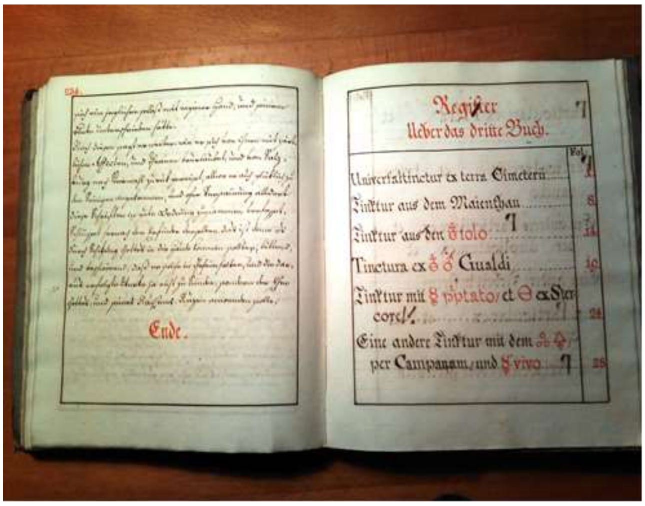

Figure 6-36: The first page of the index of the clear copy of alchemistic manuscript of Alexis Baron Ruessenstein's, the son of Konrad Baron Ruessenstein from the castle Strmol (Ruessenstein, ibid. FSLJ-29 F 54, p. 235 (The courtesy of Dr. Prof. Miran Špelič, OFM)).

Škerpin's Acquisitions of Books about Mathematical Sciences provided the basics of technical knowledges of Ljubljana Franciscans who bothered to read Škerpin's books. The Franciscan provincial Škerpin acquired an extraordinary great amount of the contemporary and older philosophical literature for the Ljubljana Franciscans' Library. His philosophy still included mathematical, physical, and biological sciences. With his efforts Škerpin paved the way for the Bavarian Franciscans Zinsmeister and Hieber who began the modern mathematical and technical lecturing in Franciscan schools nearly half of a century after Škerpin's death in 1755.

The achievements of Jesuit scientists were thoroughly researched during last decades. It was considered that you could find a Jesuit behind most of the scientific accomplishment of 17th or 18th centuries. The idea was not far from the truth because Athanasius Kircher or Rudjer Josip Bošković really proved to be among the best. But the Jesuit studies seem to have passed their peak and it is high time to research the early modern science success of the other religious orders. The Parisian Minim Marin Mersenne (* 1588; OM 1611; † 1648) was in a way the German-Roman Jesuit Kircher's match and several Franciscans were not much less important. Therefore, it is high time to give the Franciscan scientists of the past centuries the fame they earned.

Figure 6-37: Alexis baron Ruessenstein about the Quicksilver in his original handwriting in Ljubljana Franciscans' Library (Ruessenstein, ibid. FSLJ-29 F 56, p. 93 (The courtesy of Dr. Prof. Miran Špelič, OFM)).

We celebrated the 800th anniversary of Franciscan order in the year 2009. The Franciscans of the Carniola's capital Ljubljana (now Slovenia) were mentioned for the first time in 1242, soon after the establishment of Franciscan order. Later they were unable to survive the protestant challenge in 1569,[711] when almost all citizens of Ljubljana accepted Luther's Christianity. After several decades, the Franciscans returned to Ljubljana, but after the death of the Emperor Josef II Gabriel Gruber's best student Jožef Marija Šemerl rearranged former Franciscan monastery for the purposed Lyceum. Gruber was among the best engineers in Habsburg Monarchy and later became the General of the Jesuits' Order. After the earthquake (1895) Ljubljana got its marketplace in the former site of the Lyceum. In the meanwhile, the Franciscan baroque monastery with now Franciscan church of St. Mary's Assumption stood still, even if Mary had to give up her square's name to the best Slovenian poet Franc Prešeren for the sake of the Communist Regime in 1949. Between the years 1646 and 1660 the Augustinian church

711 Stanislav Bahor, Samostanske knjižnice na Dolenjskem. Frančiškani in knjižnica Frančiškanskega samostana v Novem mestu. *Rast*. 66/3-4 (205) pp. 387-409. Here pp. 396, 397, 398.

was erected on behalf of the Baron Konrad Ruessenstein from the Upper Carniola castle Strmol. The front walls were finished in 1700, and half of a century later the famous Italian sculptor Francesco Robba made the main altar. The Emperor Josef II suppressed the Ljubljana Augustinians in 1784 and somewhat later gave their monastery and church to their Franciscan neighbors from the opposite side of Ljubljanica River. The Barons Ruessenstein did not care much for the change and still took care for the church. The Baron Alexis Ruessenstein gave his important alchemical manuscripts to the new monastery owners, the Franciscans.[712]

Žiga Škerpin renewed the Franciscans' Library which was in his times on the right side of the Ljubljanica River. He was the provincial of Croatian-Carniolan province between the years 1732-1735 and again between the years 1745-1748. He became the court's secret advisor,[713] and acting general definitor of all Franciscans. During his numerous travels through the foreign metropolis including Italy and Spain he collected books for Ljubljana Franciscans' Library established soon after their supposed arrival in 1233.[714] Between the years 1733-1746 Škerpin brought to Ljubljana no less than 1668 titles of the books which were published in 2627 volumes. We'll deal mostly with the mathematical-technical part of his contributions to Ljubljana Franciscans' Library.

In 1744/45 Škerpin also rebound a great deal of his books which he inherited from his predecessors in Ljubljana Franciscans' Library, although that part of his work is valued differently by modern researchers of Ljubljana Franciscans' Library because older covers and some marginalia were lost in the process. It is said that Škerpin got many of his new leather-bound beauties almost for free during his frequent travels through Italy and Spain, because he just knew how to behave in the learned European societies. He brought so many newly printed items to Ljubljana that he had to rebuild the new library facilities in the Franciscan Monastery on today's Vodnik Square in Ljubljana. I am sorry to say that those Škerpin's accomplishments did not benefit much his Franciscan descendants because Škerpin's Franciscan monastery was rearranged to serve the purposes of Lyceum soon after Škerpin's death.

Žiga Škerpin did not only considerably extend the rooms of Franciscans' Library. He wrote several textbooks although they were used in manuscript form and were not printed. In the Trsat above the Croatian Rijeka and in Croatian north-western city of Klanjec he accomplished the textbooks on Aristotle's physics with the descriptions of the up-to-date modernized achievements. His manuscripts are still preserved in Ljubljana Franciscans' Library today.[715]

The Ljubljana Franciscans also acquired Johann Michael Conradi's optics which marked the beginning of endoscopy, the optical examination of the inner hollow organs of human body. Conradi was a teacher at grammar school in Bavarian Coburg and later became a castellan master of French language in Dresden. His publication was approved by the Philosophical faculty of the Jena University. Conradi dedicated his work to the duke of Saxony, Anton Ulrich. According to the statement on the back cover the previous owner of Conradi's book before the Ljubljana Franciscans was Anton Dr. Benedikt zu Lockerberger in 1737.[716]

6.5.3 Early Franciscans in Ljubljana Questioned the Vacuum

The Ljubljana based Franciscan scholars learned their early opinion about vacuum from the book Walter Burley (Burleaus, Burleigh, * about 1275; †

1244/45), who received a PhD in Paris and, since 1324, worked on Sorbonne as the opponent of Ockham with his razor included. A hundred years later writer Arnu (Niccolò Arnù, 1629 castle of Mirecourt "six miles" from Verdun-1692 Bologna), whose works the Franciscans also read in Ljubljana, also quoted Burleigh.[717] A Dominican monk (Praedicatorum) Arnu (Arnù) served as professor of metaphysic in Lyceum of Padua.

Figure 6-38: The title page of Burleaus's philosophy with physics of vacuum in the Ljubljana Franciscans' library.

Burleaus wrote about vacuum (Vacuo),[718] as usual, within remarks to the fourth Aristotle's book of physics. Burleaus was interested in linear motions in a vacuum, where in Aristotle's style he raised objections and dismissed them. He tried to determine the ratio between the vacuum and the full amount of matter in terms of time and speed, while proving that movement in a vacuum is not possible.[719] Burleaus illustrated the relationship between vacuum and fullness and movement in them by a cute picture. He imagined the points of time noted by a and b and denied the possibility of motions in a vacuum. He quoted both Greek and Arabic sources for his ideas of weight.[720]

Figure 6-39: A sketch of a movement in a vacuum after Burlaeus's fourteenth-century sugestions, which were printed in Venice even two and half century later (Burlaeus, 1609, 479; F).

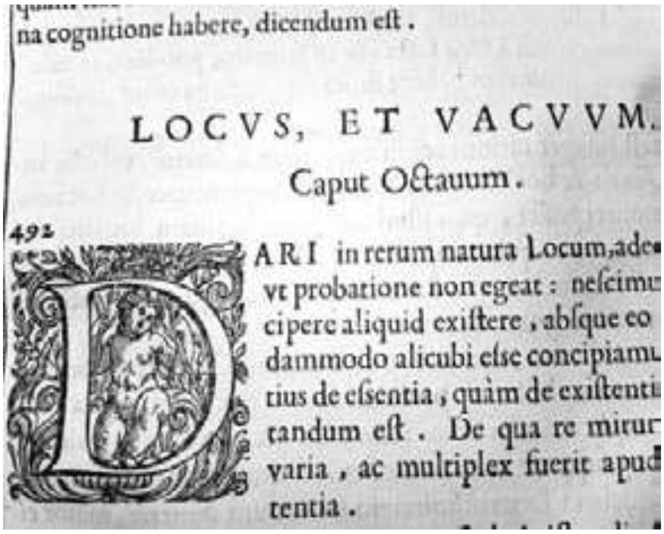

Figure 6-40: Nicely decorated initials of the Chapter on Vacuum in great Work of the Cardinal Pallavicini (Sforza Pallavicini, 1625, 90); F.

The Ljubljana Franciscans read the philosophy of Franz Titelmann (Titelman, * 1498 Hasselt in the district of Liège; OFM cap; † 1537), who taught in Leuven and defended the ideas of Erasmus of

[717] Arnu, 1685, 149.

Rotterdam; finally he joined the Capuchins. Titelman shared Aristotelian opinion about the impossibility of natural vacuum; he provided a Cartesian example of water in a glass and the water clocks (gnomon).[721]

Figure 6-41: The picture of Roman Emperor in the middle of his Battle Vortex, when a swarm of bees came to his aid, dedicated to the Pope Urban VIII whose coats of arms included those bees. That almost meter long fold picture was included in a book of Sforza Pallavicini kept in Ljubljana Franciscan Library (Sforza Pallavicini, 1625); F.

In September 1625 the marquess Pietro Sforza Pallavicini from important Parma family dedicated his book World of Philosophy to the pope Urban VIII. The book was his doctorate in philosophy at Roman Jesuit College. Žiga Škerpin, the Head Ljubljana Franciscans, acquired that book a century later. Pallavicini's defense was adorned by a great public. Besides the Pope himself, twenty Cardinals also attended that fest. Pallavicini otherwise printed the last pages of his book also in separate edition on ten sheets full of praise of Pope the Platonist, his bees, and even the bees of king Heron.

Pallavicini glorified the Pope with two big images full of Barberini's bees. That honor certainly brought enough money for luxurious edition of the book and later brought the red cardinal hat to Pallavicino in the year 1659. Antonio Tempesta (1555 Florence-1630 Rome) painted the bigger picture 70 cm long. The son of Matthias Greuter (ca. 1566 Strasbourg–1638 Rome), Joseph Federic Greuter engraved it with a motive design of Roman Emperor. The emperor took advantage of his friendly bees to overcome the Germans. Pallavicini also provided the dedication songs on the end of book filled with the motives of bees. Pallavicini became a member of Galileo's Academy dei Lincei in the Year 1629. In the year 1624, however, Pallavicini defended Galileo from accusations of Jesuits. After Galileo's conviction in the year 1632, Pallavicini felt out of favor and had to serve at province together with his friend Giovanni Ciampoli who was a member of Academy dei Lincei already in the year 1618. Barely after his cunning entrance into Jesuits' society despite of the opposition of his father, Pallavicini has returned to the Roman metropolis to which lead all ways. Between the years 1639 and 1643 Pallavicini taught philosophy at Roman College, then he became the professor of theology for eight years. The famous speaker Pallavicini wrote book on language style in scientific writing, that Škerpin read in his Ljubljana Franciscan's headquarters.[722]

Pallavicini split his philosophy into three books, among which he focused on mathematical sciences in the middle second book. So, in his great custom he adjusted Aristotelian scheme in modern ways. Despite of that Pallavicini was not very kind to Democritus', Epicurean or Lucretius' support of the vacuum without viscosity. Pallavicini used the publications of Leyden Professor of Literature Joseph Justus Scaliger, of Graz Professor Del Rio, Zabarella, Burlaeus (Walter Burley), Scotus, and Duran, probably Jacob Honoratus Durand.[723] Pallavicini outlined the mathematical sides of sciences even through Plato, Pythagoras and Averroes,[724] which has been good for the promotion of Galileo, although Pallavicini did not mention his friend Galileo by name. Pallavicini stressed the successes of chemists in their research of new substances, specifically mercury and other metals.[725]

Despite of his membership in Galileo's Academy dei Lincei, Pallavicini in "Mathematical" way refused nine years previously officially prohibited Copernican movement of earth with other worlds included. Pallavicini insisted in assumption of four elements.[726] Of course, knew all the details about

usefulness of Supernova from Year 1572 for the determinations of size of the planet Venus as it attained the apparent magnitude of Venus (about −4) seen by daytime. Pallavicini also followed the observations of constellation of Cygnus (Swan) from the years 1600 and 1604.[727] Pallavicini even did not neglect the celestial densities and rarefication including the recently discovered sunspots.[728] Despite Tycho's concerns, Pallavicini still classified the comets among the meteorological evaporations of earth in the highest areas of atmosphere, and not among the celestial phenomena.[729]

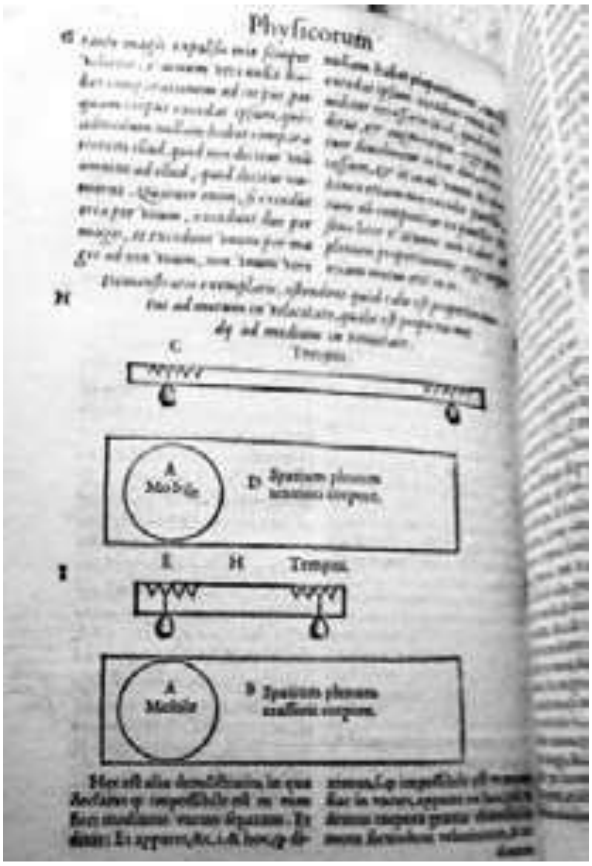

Figure 6-42: Picture used to illustrate the movement of substances in Zimara's summary of Aristotelian and Averroes's works in Ljubljana Franciscan library (Aristotle, 1562, 158v (FSLJ-5 D 4)); F.

The regent in Parma High School, the lector in monastery of John the Evangelist and Paduan professor of Metaphysics Franciscan Philipp Faber (Fabri, Faventino, * 1564 Spina di Brisighell in District Faenze; OFMconv 1582 Cremona; † 28. 8. 1630 Padua) was among the strong favorites of his Ljubljana Brethen, who purchased two Venetian editions of his natural philosophy. In Padua during the year 1603-1606 Faber was professor of philosophy, and then he taught theology; in 1625, he became the provincial. The earlier second edition of his book issued in 1602 was used by Joseph, probably Jožef Urbanizi, who has lectured on philosophy in Novo Mesto (New town) until his death. Faber has compared Averroes' and Scotus' opinion on the vacuum. He referred to Avicenna's and Allessandro Achillini's (b. 1463; d. 1512) description of the movement in the vacuum and approved Zabarella's critique of Averroes. [730] Faber discouraged the description of the vacuum of Francisco Piccolomini,[731] because Piccolomini supposedly falsified Scotus' opinion. Between 1561-1601 in the Paduan University, Piccolomini defended Averroes' version of Aristotle, combined with Plato's philosophy. In 1584, Piccolomini has been in serious conflict with a fellow professor Zabarella,[732] whom Faber in his attempts against Averroes most passionately supported and quoted. Of course, Zabarella's most powerful books were also in Ljubljana Franciscans' library together with the transparent summaries of Aristotelian and Averroes' works produced by Paduan professor Zimara, which was also acquired by Škerpin. The Ljubljana Franciscans inherited even Aristotelian work with Averroes' comments from the year 1560, which was owned by their predecessors in today's Prešeren square, the Barefoot (Discalceati) Augustinians, in 1664. The most inflamed reader of Zimara's and other compilations of Aristotle was Leonard Butorčič (d. 16. 2. 1657 Trsat), who has been for a while Guardian (Custos). He put his inscription into the bookplates of many Ljubljana bookand especially in two Zimara's editions. The alleged Leucippus' teacher Eleatic Melessius (Melissus, Μέλισσος ὁ Σάμιος; fl. 5th century BC) from Samos enabled the modifications of advocates of moving in vacuum space despite of Plato. Zimara sketched gradually decreasing resistance of the surroundings made up of the solid matter, liquids, through the air all the way to a vacuum without a viscosity. The vacuum supposedly did not allow the pushing of the motors and would thus prevented the movement itself.[733] The Pythagorean Xuthus thought about the

[733] Aristotle, Averrois, Zimara, Mantini, 1562, 149r, 152r, 158r, 158v, 162v.

possibility of separating and isolating the vacuum which could allow the motions in full limited cosmos.[734] In any event, Zimara at least did not mention the ecclesiastical authorities in this scientific dispute, as it became habitual later, and he even contributed interesting sketches. Zimara pointed out Gallen's error in describing the Aristotelian concept of time.[735] In his text printed in smaller characters at the end, Zimara stated Boethius' and Bachonis' (Roger Bacon OFM) opinion about the Aristotelian fourth Book of Physics.[736]

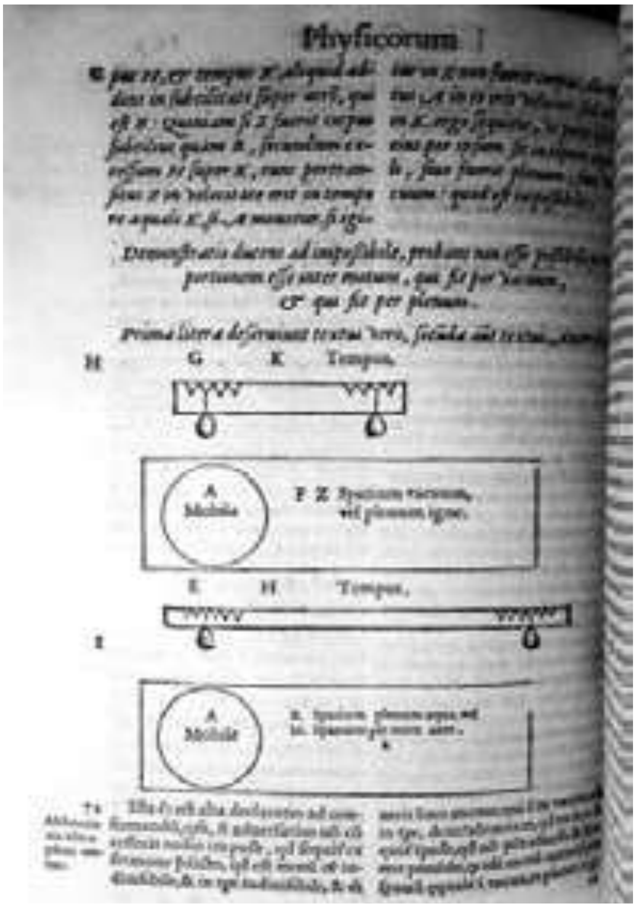

Figure 6-43: Picture used to illustrate the allegedly impossible movement in vacuum full of fire. Under it there is a sketch of motions in water and air by Zimara's Summary of Aristotelian and Averroes's works in Ljubljana Franciscan library. The first uppermost illustration (litera) designs allegedly right course of developments; the other illustration tried to check out the error in Averroes' opinions (Aristotle, 1562, 162V (FSLJ-5 D 4)); F.

The pagan Hellenist Temistius (Themis, Themistus, Themistius, * 317 Paphlagonia in central Anatolia; † 388 Constantinople) was a senator and city prefect of Constantinople, where he also taught eclectic philosophy of Aristotle mixed with Plato and religious freedom for two decades.[737] The editors of his book were Hermolao Barbaro and Marc Anton Zimara.[741] Barbaro and Zimara resolved alleged antic contradictions. Škerpin acquired that book for Ljubljana Franciscan Library. Among the first of that sort in his era, Zimara did not discuss much of Aristotelian physics books. So, H. Barbaro provided enough details to address the fourth Aristotelian book of physics with a discussion of vacuum included. For example, he described the water clock and introduced Democritus and Leucippus' vacuum as a tool for the separation of Particles of Substances with the endless empty spaces of universe. Against Democritus and Leucippus, the Aristotelian Barbaro highlighted Zeno's Paradox, Melissos of Samos and Xuthus alias Bouthus, just like Marc-Antonio Zimara did in the posthumous edition of his book in the year 1562. The problem with vacuum was its absence of volume, although the fans of Pythagoreans placed a lot of vacuums into the Universe, and Plato approved voids in his Dialogue Timaeus.[738]

Cardano's works, which were often purchased by the Franciscans of Ljubljana, were created from completely different aspirations. The famous Italian mathematician Cardano skipped different themes from chapter to chapter; he did not write directly about the vacuum, but much more about siphons and related vacuum devices which used water,[739] the ship on the ropes under the sea connected with five other ships as a submarine.[740] He did not forget the Archimedes spirals for pumping; his flow of air was upgraded with sketches of water mills at the end,[741] and he described the motion of the universe and the solar clock.[742] Of course, everything sold well because several Cardano's works were long on the Papal index of prohibited books.[743]

Figure 6-57: The spine of Tartareti's († 1522 Paris) Philosophy bind in leather full of his insightful descriptions of vacuum and atoms (Tartareti, 1621); F

Among Butorčič's writers was the particularly famous Scotus' fan Peter Tartareti (Tatareti), the professor and lecturer of the Paris theological faculty. That's why Butorčič got two of his books, even if he wrote his proprietary entry only in the first volume devoted to logic while in the second volume about the physics and metaphysics the title page was lost in the storms of the centuries. The Cistercians of Stična also read Peter Hispanus' (supposedly later Pope John XXI) Summulae in Basel edition of the magister Peter Tartareti (1514) with the additional notes about six Aristotelian books of the editor master Martin Molenfelt from Livonia by Baltic.

The volume consisted of two parts (NUK-5070; NUK-5071) bind with the cardboard while using the leather for spine and the edges. The format was A4 (similar to Imperial Octavo), 4 cm thick, without any bookplates. Tartareti had published images of global astronomical systems. Even before the second half of the book, he explained *Isagoge (Εἰσαγωγή)* of Porphyry of Tyre (Πορφύριος, c. 234 – c. 305 AD) by the books of Aristotle logic. In the item bind to it (Adligate, NUK-5071), Tartareti commented on the books of

the Aristotelian Philosophy of Nature, which filled the last half of the book. He described physics, production by decay, and then pictures of winds in the chapter on meteorology,[744] and finally wrote about the soul, metaphysics and Ethics in Aristotelian frames. In Ljubljana Franciscan copy of Tatareti's comments on physics we read about Anaxagoras's, Pythagoras's and Democritus's concept of vacuum or atoms. Nonetheless, scholastic fear of empty prevailed.[745]

Figure 6-60: The title page of the Aristotelian Parisian collected works of Professor Du Val of 1629 in the Ljubljana Franciscan Library.

Of course Škerpin was in no way left behind Butorčič; so, he also obtained the mighty Greek-Latin adaptation of the collected Aristotelian works produced under the goose-pen of the Parisian Professor Guillaume Duval (Guglielm du Val, * about 1572; d. 1646); both of those bulky books are so full of knowledge that they cannot be lifted without a great force. Duval from the Parisian medical faculty of course there bilingually refused vacuum (Inani);[746] such approach dogged the Aristotelian fans for two millennia.

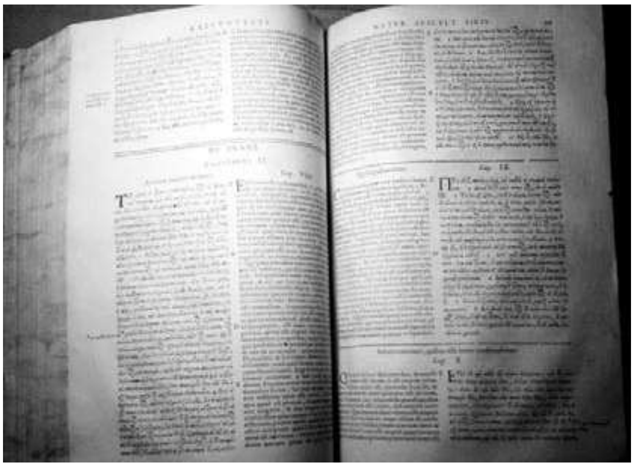

Figure 6-61: Aristotelians accidentally scorned vacuum for the next two millennia in the Parisian collected works (Aristotle, Du Val, 1629, 358) in the Ljubljana Franciscan Library.

Figure 6-63: The title page of Bacon's book published in Leyden in the year 1636 in the Ljubljana Franciscan Library (Bacon, 1636).

In Leiden the later provincial of Castilian Franciscan province Gaspar de la Fuente (Caspar, * about 1596; OFM; D. 1665) published Scotus' issues of Dialectics and physics with in-depth treatment of the vacuum read by the Ljubljana

[746] Aristotle, Du Val, 1629, 358-364.

Franciscans. As an example, he indicated the water clock (gnomon),[747] and his key objection against the vacuum was again redeemed by the grave personal problems of flying angels who were supposedly unable to use their wings in vacuum. Fuente noted Burleaus and others against the allies of the Averroes to get rid of the vacuum.[748]

QVÆSTIO SECVNDA.

An possit dari vacuum per Potentiam Dei absolutam.

Figure 6-64: Rubeus published in Latin language about the almighty Creation of vacuum with added leaf of notes of Ljubljana reader in German language (Rubeus, 1653, 1:348); F.

The Ljubljana Franciscans have purchased several books of the famous beginner of the contemporary natural sciences Francis Bacon. Bacon was already fully hospitable to vacuum in his small booklet of 1636. [749] Similarly, Bacon recognized voids in his posthumously issued tiny booklets on winds where the Ljubljana Franciscans read Bacon's praise of Epicurus' Atomism.[750]

Škerpin also acquired the book of Paduan Franciscans Barthol Mastrio de Meldula and Bonaventura Belluto Catanensi. Mastrio de Meldula and Belluto Catanensi commented Aristotle's books of metaphysics and physics. They accomplished their work on physics in 1644 with a little help of the Archbishop Cardinal Alois Caponio. They tried to measure the relations between the empty vacant spaces and matter in the universe. Their main questions were still the possibilities of translation in vacuum. It's a pity that they did not bother to learn about the barometer which Evangelista Torricelli described for the first time in his letter to the young future Cardinal Michelangelo Ricci dated on June 13, 1644, in the same year when the Paduan Franciscans published their book.[751]

Figure 6-65: The title page of second part of Merinero's Course of Philosophy with the propriety entries of Brenn and Budnović in Ljubljana Franciscan library (Merinero, 1659); F.

The reformer of the Academy Degli Imperati, Barthol Mastrio de Meldula (b. 1602; d. 1673) and Franciscan from the Paduan college Bonaventura Belluto Catanensi (* 1599/1600; d. 1676) have published comments to the Aristotelian Books of metaphysics and physics. They published their comment on physics together with the Archbishop Cardinal Alois Caponio in 1644. They described vacuum in the fifth Book of physics between chapters 12.1. and 12.8. They were interested in the relationship between the vacuum and the fullness, but especially in the movement in the vacuum. Of course, they have not yet known the Torricellian barometer which was for the first time

described in the year of issue of their book.[752] The excited Ljubljana Augustinians immediately purchased Mastrio De Meldula's book without a delay.

On 29. 6. 1725, the Ljubljana Franciscans additionally purchased even the posthumous issue of Barthol Mastrio de Meldula's (* 1602 Meldola; OFMconv; † 1673 Meldola) philosophy with physics in three books of giant volumes. On that occasion, the Ljubljana Augustinians couldn't cope with them, because Josef II in the meanwhile suppressed Augustinians' monastery and put Franciscans in it. The greatest range of big book itself did not improve wrong Mastrio De Meldula's opinion that vacuum provides no resistance and so also no sequence of movement.[753] Alessandro Rubeus quoted his religious co-brother Mastrio De Meldula's options for movement in vacuum.[754] Also Rubeus (Rossi da Lugo) as a Franciscan conventual lecturer in Bologna and Assisi used to be quite certain that the almighty God can create the impossible Vacuum.

In 1744 Škerpin provided new bindings for many Franciscan books in Ljubljana, among them for the Scotus's philosophy of Madrid Franciscans' lecturer of theology, Joanes Merinero, who got promoted to a bishop of Valladolid in 1647. The Ljubljana Franciscan Lecturer, provincial, and later Bishop in Istria Pavel Budimir previously kept the item in his rooms. Merinero opposed vacuum as the strict follower of Aristotle. For him, and he was not alone at all, the vacuum was in opposition with nature because the bodies were not able to take any move in vacuum as Franciscan Scotus stated many centuries ago. The main Merinero's question was the possibility of progression in the empty space. Is the translation there momentous or it takes considerable time anyway?[755]

Physicarum
Opticarum
Ethicarum
GREGORII STANNARII,
16 61.

Figure 6-67: The title pageof Stannarius' System in the Ljubljana Franciscan Library (Stannarius, 1661).

Sixty-fifth General Minister of the Castilian Franciscan Province and former minister general of all Franciscans in 1639-1645, the bishop of Valladolid Joannes Merinero (Juan, * 1600; OFM; died 1663) published comments on eight Aristotelian books of physics with a hefty discussion on the vacuum printed in his domestic Madrid in 1659. Merinero's chief reader was the Ljubljana Franciscan Marci Brenn and after him Paul Budimir (Budnovich), who was among the leading officials in the Ljubljana Monastery during the years 1662-1668. He became the general Definitor and Pičen (*Pedena*) Bishop. Škerpin has bind all four Merinero's volumes with the new semi-hard parchment binding in 1744. Merinero used primarily the works of his countrymen Benedictus Valentin Pererius.[756] Otherwise, he

[752] Mastrio de Meldula, Belluto Catanensi, 1644, 5:888 (Chapter 12. 1.), 898 (Chapter 12. 1.), 901 (Chapter 12. 1.).

behaved similarly antagonistic to the poor Averroes as Merinero's foremost compatriot and associate on the eminent functions of their order, De la Fuente.

In 1661, Gregorius Stannarius (Kangießer, b. 1610 Marburg; d. 1670 Marburg) published *Systema regularum Philosophorum* which the Ljubljana Franciscans read. Stannarius was the Kassel of northern Hesse professor of philosophy and then Marburg Professor of philosophy and theology. He discussed vacuum only briefly, even if the Torricellian barometer was already old news in his times.

Figure 6-68: The spine of Oviedo's work at the Ljubljana Franciscans' library (Oviedo, 1663)

The Ljubljana Franciscans acquired the posthumous philosophical course of Franciscus de Oviedo (* 1602 Madrid; SJ; D. 1651) published in 1663. He cited his Spanish co-brothers, the Jesuits Arriaga and (Gabriel) Vasquez against the vacuum.[757]

The Jesuit from Cambridge Thomas Compton Carleton (*1592 Cambridgeshire; d. 1666 Liège)

[757] Oviedo, 1663, 324.

Figure 6-69: A dedication picture of Bavarian electoral prince Maximilian in the volume of Carleton alias Compton's philosophy with the physics of vacuum from the Ljubljana Franciscan library (Compton, 1664).

had to teach theology at the English college of Liège instead of his native country, but this gave him the opportunity to dedicate his own bulky philosophy to Bavarian electoral prince Maximilian, of course not for free. Carleton's Disputations did not quite follow the Aristotelian frames. So, he set his 32nd Disputation about the space and vacuum immediately after he finished his second Aristotle's Book of Physics. Carleton felt that the vacuum can be experientially perceived in fantasy spaces outside the universe (Spatia Imaginaria extra coelum Empyreum Dici possint vacuum). It seemed to him that the movement in the vacuum was not necessarily timeless, but the Earth was still his center of the universe. He rejected Descartes including the Cartesian refusal of the vacuum,[758] which may have been an additional reason to buy Carleton's book for the Library of Ljubljana Franciscans. The

[758] Compton, 1664, 332-334.

system of Tycho Brahe and Clavius with the fluid universe seemed to be the best for Carleton's clarification with the telescopic images of sunspots.[759] Carleton felt no need to specially note Galileo, Torricelli or Copernicus who were not specifically highlighted. The Ljubljana Franciscans also read Compton's theological books.

The Franciscan John Punch published similar opinions about vacuum like Compton but Punch disliked vacuum even more. His Ljubljana co-brothers read Punch's work in two different editions. Punch studied in Leuven and Cologne. He participated in the editing process of Scotus' collected works. In 1630 he became Chancellor-rector of the Roman *Collegio Ludovisano*, and in 1648 he returned to Paris.

Figure 6-70: The title page of the newer and larger among Poncius' (Ponce) books at Ljubljana Franciscans' library (Poncius, 1672). The Irish Observant John Punch (Pontius) quarrelled with the Conventual Bartholomew Mastrius and his collaborator Bonaventure Belluti because they were the members of the different independent branches of Friars Minors and Punch was not so strict follower of their common teacher Scotus. The Ljubljana Friars Minor Observants acquired books of both quarreling parties even if they sided by their own John Punch

The older Roman Imprint of Punch's (Poncius) Philosophy issued in 1642-1643 was also purchased in Ljubljana. Its happy erudite owner was Johann Baptist de Presheren von Heldenfeld probably the lay brother Ivo Prešeren. He was the ancestor of Janez Prešeren von Heldenfeld and his son Janez Prešeren von Heldenfeld (* Lesce in Gorenjska; d. 17. 6. 1814 parish Brezovica), the husband of Maria Prešeren (* 12. 11. 1837). He was the ancestor of Joseph Mathias Prešeren von Heldenfeld of Radovljica, who defended the philosophical-theological examination thesis in connection with the vacuum in the class of professor Janez Baptist Mayr in Ljubljana in 1728.[760] Both editions of the work of Punch (Poncius) were likely the same, except that the earlier Roman edition used 22 cm tall octavo format divided into three volumes while the later Leyden printer published in much taller 37 cm folio format. Punch (Poncius) argued that in nature the vacuum is not possible. Anyway, according to the influential book of Madrid experts (Complutensibus, Universidad Complutense de Madrid), Punch (Poncius) believed in a miraculous creation of vacuum needed even for angels' flights.[761] Specifically, Punch (Poncius) thought about the possibilities for movement in the vacuum regarding the stone that's thrown from the moon towards the earth. If there is a vacuum in between, the movement of the stone would have to happen momentous. Similarly, the ray from the sun would come to us momentously, as it would not have encountered any resistance in the vacuum in-between.[762]

Philippe du Trieu lectured about the philosophy in Douai. In 1716, Sigismund Anton Joseph Ursini Count of Blagaj (b. 1686) bought his posthumous separately paginated booklet about Physics printed in the year 1670 bound to Treu's logic and dialectic issued in the year 1675. Trieu has described the vacuum,[763] but he died too soon to mention the just invented barometer.

In 1669 in Leyden the father Bonaventura Columbus (Columbi, * 17th century in Nice; OFMconv) published a complete course of Scotus' philosophy in a weighty book that you could barely

[759] Compton, 1664, 398, 400.

[760] Mayr (Mayer), Presheren, 1728 (FSLJ-5 D 21).
[761] Poncius (Punch), 1672, 557, 559; Poncius (Punch), 1642, 479, 484.

lift on, let alone read. He was profoundly inspired by his religious co-brothers Barthol Mastrio de Meldula and Bonaventura Belluto Catanensi. Columbus devoted some of his hefty pages to the vacuum in Aristotelian and Scotus' spirit of his days. As it was fit for a Franciscan, after dialectic and a rational philosophy, he embarked on the philosophy of nature or physics and described in the third question of his sixth book the problems of the vacuum in frames of Aristotle's fourth book of Physics. Of course, he supported Aristotelian criticism of Pythagoras' fans with the nature which is afraid of the vacuum.[764] He mentioned Mayr, Bonet's translation of Rohault's physics and Magistris de Montis' (Regiomontanus') Incunabula, which was also purchased by Ljubljana Franciscans. Columbus was really very funny in his discussions of the possibilities for the flight of chubby angels in the vacuum.[765] Nonetheless, the will of God's almighty allowed a vacuum with us and above the moon, but Columbus forgot to mention a quarter-century old barometer and vacuum pump.

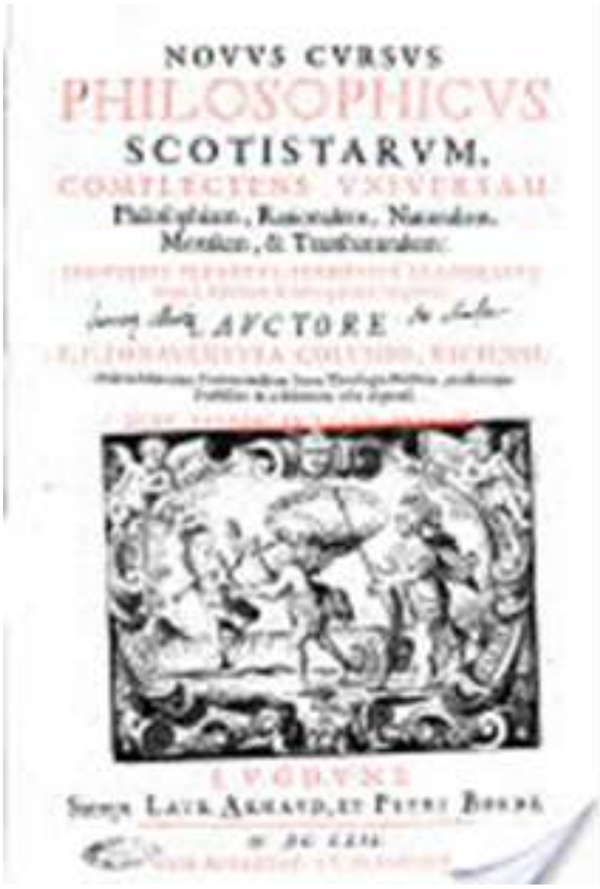

Figure 6-71: The title page of Columbus' discussions on philosophy, physics and Vacuum from the year 1669.

The Franciscan Livio Rabesanus da Montursio of Vicenza (b. 1605; d. 1664) criticized Pythagoras' description of the vacuum in his posthumous edition of 1665.[766] Montursio's book was used in Trsat above Rijeka by Peter Francetić who used to be a general lector, former provincial, three times definitor, general commissary and visitor of Franciscan provinces of St. Ladislaus in Slavonia, St. Savior in Hungary, St. Leopold in Tyrol, and St. Venceslaus in Bohemia. Later, the Montursio's book was placed in the library of Ljubljana Franciscans. In Ljubljana, Pavel Budimir also used the same edition bind to the physics issued in 1664. Rabesanus da Montursio discussed the results of the Jesuits from Coimbra, Ruvius (Antonio Rubio), as well as Fuentes and Poncius who were also read in the Ljubljana Franciscan Library.[767] Rabesanus de Montursio already supported the placeable position by which God can make weird things, including even a strange vacuum.[768]

Figure 6-72: The title page Regiomontanus' incunabula from 1490, cited by Columbus in 1669.

The Spanish professor of theology in Florence the Franciscan Thomà Llamazares published two questions about the nature and the movement in the

[768] Montursio, 1665, 439.

vacuum; the latter was again primarily focused on the problematic flying of angels.[769] Certainly, Škerpin immediately acquired that book during his visits in Spain to check those angels' abilities in person.

In 1670 the professor in Padua the Somascan father Francisco Caro described and drew the operation of Baroscope filled with mercury.[770] He even mentioned the new pneumatic vacuum pumps of those times.[771]

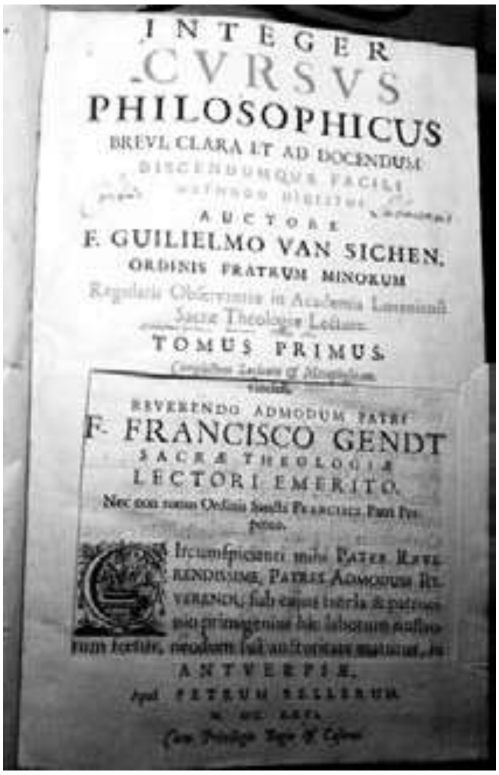

Figure 6-73: The title page of Sichen's philosophy and physics with a fair nice contemporary presentation of the vacuum. It has a cutoff emblem of Antwerp native printer Beller (Balthasar Bellère. 1564-1639 Douai) and the original bookplate of Franciscan library in Kircher's home Fulda of 1671. Later, it was acquired for the Franciscans' library of Ljubljana (Sichen, 1666).

In Leuven, the professor Willem Van Sichen (Guillaume, * 1632; OFM; D. 1691) initially taught philosophy, and then he advanced as the professor of theology according to the ideas of scholarly statuses of those times. In 1671 at the ancient University of Leuven he gave his students of theology his exam questions. They publicly defended his thesis on vacuum where he dealt with the new Oviedo's work, which was also read by the Ljubljana Franciscans. The Franciscan Sichen wrote his textbook for his religious co-brothers' lessons. He did not like Cartesians, but he still accepted some Descartes' ideas in physics, mostly because Sichen updated the teachings of his religious co-brother Scotus much more successfully compared to Mastrio de Meldula or Belluto. Sichen praised Kircher's description of the dilution of the atmosphere at the peaks of Peru, Chile and the Greek Olympus,[772] but not without the mention of Kircher's critics from Galilean circles. Even if Kircher used to be a clever guy, he was a Jesuit anyway and therefore archenemy of the Franciscan Sichen. Sichen's book was initially owned by the monks Franciscans in Fulda. The Friars minors of Fulda probably bound their slightly narrower leaves full of the examination questions of two Sichen's students of theology in Leuven. They pasted them flat against the inside of endpaper of back cover of the book.

Figure 6-74: Sichen's introductory treatment of vacuum with nicely designed initial (drop cap) of a chapter (Sichen, 1666, 2:100).

In his debate about space and time the Roman Professor Andreas Semery Remus (b. 1630; SJ; D. 1717) dealt with the vacuum and possibilities for

[769] Llamazares, 1670, 243-246.

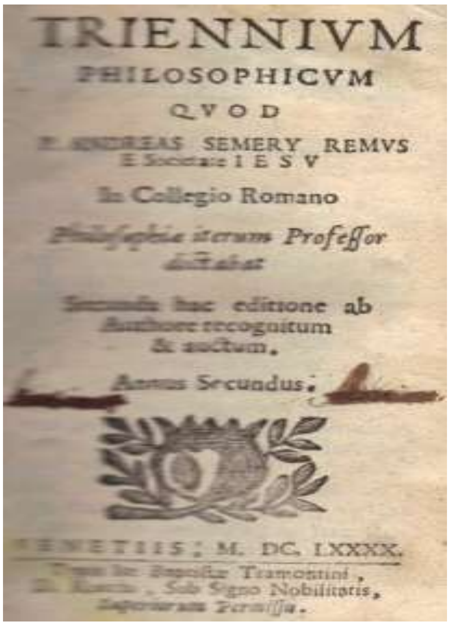
movement in it following the ideas of Aristotle and St. Thomas.[773] Although Semery also described experiments,[774] among them we in vain search for Torricellian (1643) and Guericke's investigations of 1654. Several times Semery stated the thoughts of Valeriano Magni on the visual display of the vacuum.[775] That Capuchin Magni has been a real painful thorn in the heel of the Jesuits. In his last discussion of the second year, Semery dealt with the Aristotelian book of the Sky, and in the first debate of the third year (Triennivm Philosophicvm / 2, Annus Secundus) Semery discussed the Aristotelian books on the formation and decay. Then, Semery focused on the areas that today belong to philosophy and theology.

In 1672, the Istanbul Franciscan nuncio (vicar patriarch) appointed in 1638 Angelus Petricca (Petricca de Sonneno, *1601 Sonnino in Central Italy of then Campagna e Marittima; OFMconv; D. 1650 or 1673 Roma) posthumously published a triple Aristotelian philosophy in which, of course, there was no lack of a description of the vacuum with a nice handy conjecture that Almighty God could create an otherwise impossible vacuum.[776] Petricca was a great unionist Christian activist of ecumenism in Ottoman regions which gave a special favor to his physics.

From his extended travels, Škerpin brought to Ljubljana an interesting posthumous presentation of the "negative" philosophy of the Jesuit Antonius Forti (* 1651 Caltagirone in Sicily; SJ; D. 1707 Palermo). Forti dedicated his third and fourth books to physics among his five books. Forti discussed the possibilities of vacuum focused on belief that the empty space is maintained. In the description of the movement, Forti quoted Aristotle as well as the mercury barometer. Forti recommended the work of his religious co-brother Paulo Casati, who was very popular in Inner Austria and in Ljubljana. Forti, of course, was gravely upset by the omnipresent angels waving their wings in vain in an empty space;[777] unfortunately, he didn't think of the possibility of



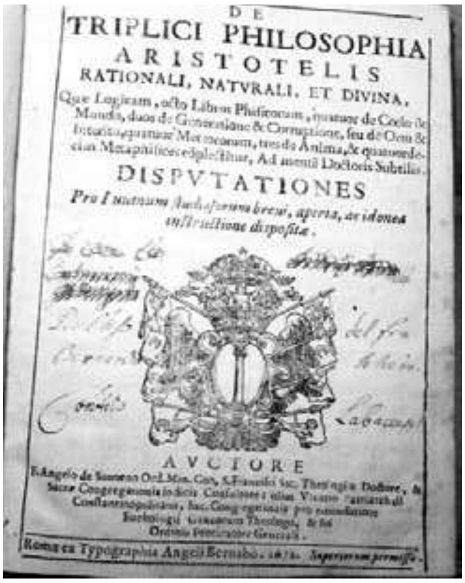


Figure 6-75: The title page of the Semery's textbook at Ljubljana Franciscans' library (Semery, 1690) and the title page of Ljubljana Franciscan book of Angelo da Petricca De triplici philosophia Aristotelis rationali, naturali, et divina, quæ logicam, octo libros phisicorum, quatuor de cœlo & mundo, duos de generatione & corruptione, seu de ortu & interitu, quatuor meteororum, tres de anima, & quatuordecim metaphisices complectitur, ad mentem doctoris subtilis. their reactive propelled rocket drives which was strange as the rocket itself used Italian name *rocchetto*. The first gunpowder-powered rockets evolved in medieval China under the Song dynasty of the 13th century and soon spread among Bavarian, Polish and Habsburgian military engineers after the Padua court physician Konrad von Kyeser[778] wrote his nicely illustrated Belli Fortis full of alchemistic and magic visions to misguide the enemy in 1402-1405. Konrad wrote down his ideas during his spare times when Barbara's imperial husband exiled him from Prague to the Bohemian mountains Burg Žebrák (Bettlern) and maybe also to his hometown of Bavarian Eichstätt north of Munich and Ingolstadt. Kyeser's magic novelties failed to distinguish himself during the Barbara's husband and father's lost battle of Nicopolis in 1396 which made Kyeser quite unpopular.[779]

The Ljubljana Franciscans were also fond of reading another Jesuit opponent of the vacuum, the Italian Jesuit Mauro, who was a professor of philosophy and an occasional rector of the Roman College since 1653 until his death. In the years 1654/55 and 1657/58 he taught physics.[780] He represented the ideas of St. Thomas Aquinas in Suárez' version. In his five books of philosophical issues, he introduced a very clear overview of Aristotle's work and developed the findings of his interpreters from the thirteenth century. The reading of Ancient Greek records has been complemented by the best Latin translations of his days. Stična monks read an early edition of Mauro's philosophy. The first Carniolan vacuumist Janez Vajkard and his brother Volf Engelbert Auersperg (Turjak) besides the later edition of that Mauro's work also purchased Mauro's interpretation of Aristotle, which found its ways into the libraries of the Ljubljana Franciscans and Škofja Loka Friars Minor Capuchins. Mauro has denied a vacuum despite Democritus, Leucippus and Anaxagoras. According to Pythagoras' fans and Plato's admirers, Mauro argued that the vacuum is not a material item, even if it enables condensation in parts of the body. Mauro recognized the steady movement in the vacuum under the influence of gravitational force but discouraged the vacuum wellbeing in the universe.[781] In his pocket edition printed two years later he described more specifically the experiments with mercury following his religious co-brother, the Jesuit Paul Casati.[782] In particular, he discussed possible vacuum flights of the naughty omnipresent angels.[783]

The French Dominican magister Niccolò Arnù (Arnu, B. 1629 Béziers; d. 1692) was a public professor of theology in Padua slightly before G. Tartini and Carli's times. Arnu wrote about the unmoved mover or prime mover (ὃ οὐ κινούμενον κινεῖ, primum movens), as well as on the theology. His book of 1685 was purchased in Ljubljana in 1726, but it probably did not belong to Škerpin's collection because it has a inscription on a bookplate over the title page without Škerpin's bookplate sticker. For the additional readings, the Franciscans of Ljubljana purchased a decade later Arnu's mathematical philosophy. The third volume of the book has dealt with eight (Aristotelian) physical books. With its own pagination, Arnu attached his second part of the third book focused on five subsequent Aristotelian books including *Parva Naturalia*. Arnu described the vacuum in his special query number 2 with two article (*Articulus*) twenty pages long. First, Arnu thought about Greek and Latin (*Inane*) term for a vacuum and quoted Lucretius' claim that the bodies are in the vacuum. By the compilations of classical author Stobaeus' (Ἰωάννης ὁ Στοβαῖος) from the Macedonian Stobi (Στόβοι, Стоби) *Eccl. Phys.* (Eclogues, Ἐκλογαὶ φυσικαὶ καὶ ἠθικαί) Arnu compared Cleomedes' (Κλεομήδης) vacuum to nobody. The vacuum was supposed to take over the pores, but Aristotle opposed any claims like that, while Epicurus, Leucippus, Gassendi and Joannes van Helmont have rejected Aristotle. Again, it seemed otherwise to Plutarch, Plato, Melisus or Eleatics Pre-Socratics. Arnu, of course, also discussed the performance of the popular pumps, where the seals prevented the return of the extracted air. Arnu reported Gassendi's opinion about them, and there were very eloquent Ctesibius' (Ktesibios, Tesibius, Κτησίβιος; fl. 285–222 BC) *Ctesibianis* over two millennia old pneumatic pumps which they called *Pompe* while the Italians called them *Selo*. For their pumping of

air upwards, they used mercury instead of water. Other pumps extracted water, and a special case was a water clock klepsydra with the axis (Kardan) used for pumping. Arnu compared the pumping process with the recently discovered (Harvey's) blood circulation. Of course, Arnu quoted Aristotle, as well as the impact of fire, demonic elements of the world and the possibility of moving angels in a vacuum. The vacuum should oppose the good regulation of the world, as indicated by the mechanism of clock. Arnu then embarked on the rejection of the opposing claims as absurd based on Aristotelian arguments, the claim of St. Thomas, Cicero and Seneca. Arnu summed up the behavior of mercury and described its partial evaporation according to the citations from the works of Albert the Great. In his second composition (*Articulus*) Arnu focused the opinions of the Constantinople imperial public speaker Themistus (* 317 Paphlagonia; † around 390), Aristoteles' commentator Simplicius (Σιμπλίκιος ὁ Κίλιξ; c. 490 – c. 56), Burlaeus, the AugustinianAegidio (Egidio Romano, * around 1243; d. 1316) as a disciple of St. Thomas Aquinas at the Parisian Faculty of Philosophy, Jandanus (of Prerugia?), the Viennese rector Albert of Saxony (ca. 1320–1390), the critics of magics of cabala and Clavius' promotions of mathematic curricula Benedictus Pererius (Valentin, * 1535 Ruzafa near Valencia; SJ; D. 1610 Rome) and many other ideas about the movement in the empty. He also cited the Madrid experts (Complutenses, Universidad Complutense de Madrid) and St. Thomas's ideas about the center of the sky. Like Burleaus before him, Arnu specifically disregarded the possibilities for movement between points A and B in the vacuum and finally solved the arguments with the assertion that the vacuum could not be, especially not in St. Thomas' networks.[784]

In 1701 in Cologne appeared the Jesuit Francisco don Mendoca's posthumous Flowers from different gardens. Among his philosophical flowers, he scorned the Copernicans with the fans of Pythagoras, Caelius Calcagninus and Augustinian Hermit Diego de Zúñiga of Salamanca included.[785] Copernicus and Zúñiga's books were on Papal index which put Mendoca in the safe side. His center of gravity rested in the center of the universe, as it was highly appropriate by Papal decree. Mendoca considered his chances to fly in the air.[786] He would even flutter to the moon during his thoughts about the nature of the fire and the resistance of the gliding vessels full of air or water.

Figure 6-79: The title page of the Franciscan Engelmayr's textbook of Physics in Ljubljana Franciscans' library (Engelmayr, 1738).

The Friar Minor Conventual (Minorite) Wilhelm Geyss published a philosophy that was purchased by his Ljubljana religious co-brothers eighteen years later. He was not particularly fond of the vacuum. Against the dilution as a removal of the substance, Geyss used the ideas of Scotus as well as the century old work of Peter Tartareti and his religious co-brother Philipp Faber, which were also read by Ljubljana Franciscans.[787]

The Franciscan professor of theology Angelus Engelmayr drew a pleasant philosophical textbook for his disciples in Linz, which Škerpin got for his Ljubljana monastery. Engelmayr's disliked vacuum. Of course, Engelmayr cited against vacuum mostly Cartesian example of emptying the cup full of wine. Engelmayr even quoted the theological writers,[788] of course, not his own opponents. Engelmayr was guardian in 1735; he published his theological books in Trnava and Košice in 1738-1770.

6.5.4 Ljubljana Franciscans in Favor of Vacuum

Soon after Valvasor's death the Ljubljana Franciscan reading about the vacuum experienced a real turnaround after which they started their regular acquirements of the books about experiments with vacuum and even illustrated

Figure 6-80: Title page of Viviani's geometry; he was the last Galileo's pupil and as the first assembled the barometer by Torricellian instructions.

them in their domestic manuscript textbooks. In such a new era the works of Cornaeus (1657), Donatus (1754), Zanchi (1754), Georg Friederich Brander (1772), Biwald (1774) or Metzburg (1791) were immediately purchased by Ljubljana Franciscans, even if they used only mathematical works of Cornaeus' collaborator Schott and did not buy the books of more famous Schott's teacher Kircher at all. Galilean original records were avoided because of Papal threats, so they read the geometry of Galileo's last pupil V. Viviani, who first assembled the barometer after the Torricellian instructions. Of course, many books of Ljubljana Franciscans' library used to favor Galileo's ideas as well as Riccioli's explanation of the weight of air.[789]

Figure 6-81: Viviani's sketch in the Ljubljana Franciscan Library (Viviani, 1746, 152).

Besides Cornaeus and Weber, the Ljubljana Franciscans and other Carniolan erudite also purchased Doreguzzius' (Natale Doregucci) book issued in 1682. Doregucci's publication was a reprint of the famous textbook of the first president of Parisian academy Du Hamel and the son of his patron the minister Colbert. The first three volumes of logic and metaphysics were published in Paris in 1678, but the entire work of six volumes divided in two books first appeared in Nurnberg in 1681. Volumes four and five focused the general physics, while the last volume six contained the third part

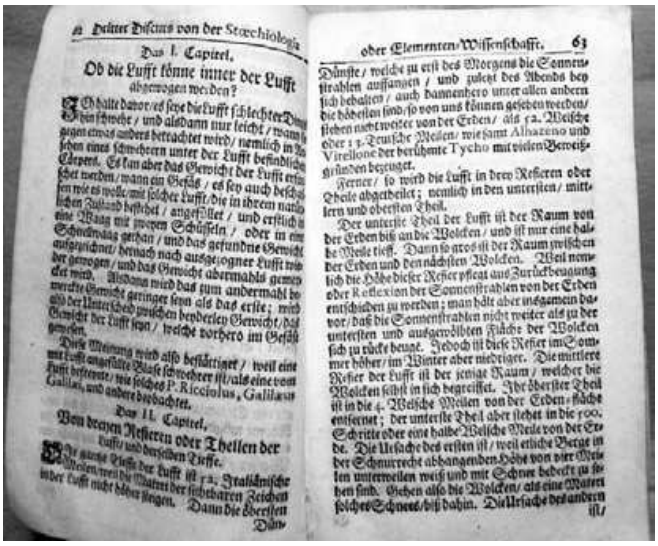

Figure 6-82: Johann Adam Weber praised Galileo and Riccioli's experiments proving the weight of air in his book kept at the library of Ljubljana Franciscans (Weber, 1677, 62). Johann Adam Weber (1611-1695) was never a Jesuit priest according to Jesuitical sources. Weber was an Augustinian professor first in Neustift in the territorial districts of Bressanone, later in Augsburg in Heiligenkreuz in 1673. Most recently Weber served as a provost of the Augustinian monastery Hegelwerth in Salzburg in 1686-1691. He also served in Augustinian monastery Neuburg in Lower Austria in the famous abbey Klosterneuburg. The Capuchins of Škofja Loka acquired several Weber's books while the number of his works in modern Slovenian libraries exceeds two dozen which made Weber one of the chief protagonists of modern new science in Carniola after the Thirty Years War. The other younger Johann Adam Weber was professor in Altenburg Grammar School in Saxony in 1745.

of physics. Du Hamel, Colbert and Doregucci were the early vacuum advocates of 1682, which was no wonder after Huygens' experiments performed in front of Parisian academy. Doregucci dedicated some of his writings to his high society friends Paolo Scipione Pelloni and Carl'Antonio Del Frate. Du Hamel and Doregucci dedicated to the vacuum and images of its experimental investigations forty pages of a small format in the last five chapters of the second tractate of the fourth book on physics with separate pagination in Doregucci's edition but not in Du Hamel's. They knew that nature was not afraid of a vacuum, which made voids possible.[790] Initially, Du Hamel and Doregucci described and

Figure 6-86: Doreguzzius on barometer and vacuum in the Franciscan Ljubljana book (Doreguzzius, 1682, 375). The same page with picture was published in Du Hamel's work (Du Hamel, 1682, 4/2: 229)

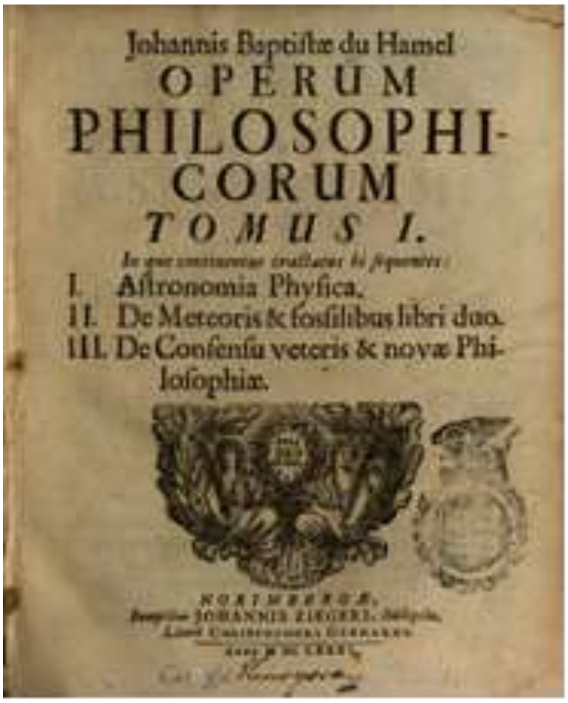

Figure 6-87: The title page of the Du Hamel's physics (du Hamel, 1681).

Ljubljana Franciscans read the Nurnberg physics of John Baptist du Hamel, who became a first permanent secretary of the Parisian Academy in 1666. He was among those experts whose books Gruber got for his department of Mechanics in Ljubljana. Du Hamel dedicated to vacuum the eighth chapter of the first part of his book according to Democritus, Cartesians and Gassendi who defined vacuum by the help of atoms.[791] In his second part, du Hamel published sketches of barometers and described the hydrostatic paradoxes of the Jesuit Honorat Fabri (Fabry).[792]

Du Hamel discussed Helmont's exploration of gases, Hooke's *Micrography*, Guericke's Magdeburg experiments with a vacuum and Boyle's pneumatic machine that has buried peripatetic physics.

Du Hamel was interested in the weight of air, so he described the Torricelli's experiment with mercury, syphon and Boyle's pneumatic pump with Fabry's interpretation, since Fabry reported of the experiment of the engineer Fabricio Guastaferro with a tube full of mercury.[793] Du Hamel has described Boyle's observation of the (phosphorescent) Bologna stone. He used Boyle's explanation of the colors and Hooke's Micrography, because Du Hamel was not yet aware of the importance of Newton's prismatic and thin films optics published a decade earlier.[794]

Figure 6-90): The title page of the Boyvin's book at Ljubljana Franciscans' library (Boyvin, 1681)

The lecturer in philosophy and Theology at the Normandy Franciscan school Jean Gabriel Boyvin (b. 1605 Vire in Normandy; OFMobs; D. 1681 Vire) wrote about the vacuum, the nature of the forces and the troublesome jumps of flying angels through vacuum. For Boyvin, vacuum was potentially possible, despite of Aristotle's arguments against Pythagoras' and Epicure's infinite vacuums between atoms of metals and rocks. According to Aristotle Horror Vacui the Aristotelian local movement should be problematic. The fluid air takes less space. Boyvin quoted the objection of Duns Scotus against the possible declining power of angels in the empty space (*Potestatem Angelica non Test Procurari vacuum*). The movement in the vacuum is continuous and successive although due to the absent resistance of the media there is no delay or the retardation of motion.[799] Boyvin quoted the Jesuits Franciscus Suarez (Suárez, Suares, 1548 Granada-1617 Lisbon), the professors from Coimbra (Coimbricensis), and Rodrigo de Arriaga (1592-1667 Prague) about the new imaginary worlds. God can create thousands of worlds, like a poet narrated,[795] therefore there is no problem for a God to create a vacuum or two of them.

Figure 6-91: : Illustration explaining the discussions of Aristotelian Materia Prima at Gottscheer's military scholastic book with a description of the vacuum (Gottseer, Krassnigg, 1690,73).

The Polish Jesuit, Persian Isfahan missionary, and Suarez's fan Thomas Mlodzianowski (Tomasz Młodzianowski, 1622 Ciechanów (Zichenau)-1686 Wolbrom (Wolfram) near Krakow) belonged to Mazovian Yeomanry (drobna szlachta). He spoke on the coronation of Jan III Sobieski in 1674. He published most of his theological and philosophical books in Mainz. Mlodzianowski added his discussion about vacuum to the very end of his philosophical book, exceptionally even after the chapters about time. The Franciscan Ludvik Gallenfels loved to read that book in Ljubljana. Mlodzianowski declared the vacuum as the negation of matter, but the vacuum is nonetheless created by the God despite of the intentions of nature which echoed Mlodzianowski's eastern ideas endorsed during his missionary activities in Persian Isfahan from 1654 to 1656. Mlodzianowski cited the Jesuits Arriaga, F. Suarez and (Gabriel)

[795] Boyvin, 1681, 1:318, 319.

Vasquez[796] who were not the fans of the vacuum. Franciscus de Ovieda provided the similar citations in his book which was also read by Ljubljana Franciscans and Mlodzianowski cited Ovieda's visions of the resistance to motions. Mlodzianowski cited the contradictory opinions of the theologian from universities of Rome, Alcalá de Henares and Salamanca Thomás Hurtado (1570 Toledo-1649), F. Suarez and Arriaga about the mixings of gases with solid matter, like the mixing of air with the earth. Arriaga believed the Stoics that the air above the areas of the clear part of sky evaporates to vacuum,[797] which is not far from modern visions except that Arriaga probably did not consider the dilution of air with the height.

Martin Gottscheer (Gottseer, * 1648 Warth in Upper Austria; SJ 1668 Leoben; D. 1731 Graz) was of Slovenian descent from Kočevje, but in the lack of domestic higher education institutions he taught philosophy with physics at the Graz Jesuit University. In 1690, Karl Josephus Taucher (Jožef Tavčar) from Graz and the Styrian Janez Jurij Krasnik (Joann Georg Krassnigg) carried out a philosophical examination for the lowest academic degree baccalaureate in Gottseer's class. Jožef Tavčar was discussing Carthusians, while Janez Jurij Krasnik published a Gottseer's speculation about Aristotelianism applied to the military science. Janez Jurij Krasnik dedicated the writing of his teacher Gottseer to his benefactors, the five counts of Lamberg from Ortnek, although their manor Ortnek was already sold before those times. Janez Jurij Krasnik praised the talent of Melhior's brother Sigismund Lamberg.[798] In fact, he followed the chapters of the Aristotelian Books of logic, physics, the World and the sky and the souls. Each Scholastic chapter has been supplemented by a chapter on related military know-how with a total of ten images. Gottseer described vacuum as a place without bodies, which is not present in Nature. Nevertheless, two bodies pressed to one another could eliminate the air between each other to establish a vacuum; almost two centuries later J. Stefan proved that it never happens, but Stefan was already able to provide many other proofs for the funny existence of vacuum. Gottseer's visible agents cannot empty the vacuum in nature. The weight and lightness are caused by movement: because in a vacuum there is no resistance to the motion, the movement in a vacuum is not possible, at least such were the naïve thoughts of Gottseer.[799]

Figure 6-92: Picture before the title page of Gottscheer's military scholastic book with a description of the vacuum (Gottseer, Krassnigg, 1690).

The canon in Würzburg Joannes Zahn (b. 1633 Karlstadt; d. 1707) was member of the order of Premonstratensians founded by Saint Norbert of Xanten (Gennep, c. 1075 Xanten-Magdeburg–1134), the son of Heribert Count Geneppe. Joannes Zahn has published such a gigantic beautiful book that would be a real miracle if Škerpin would not have bought it. Zahn became professor of mathematics at Würzburg University, the canon and the abbot of Premonstratensian monks between 1685-1707. He used the camera with mirrors that Johann Sturm developed in 1676. He put both concave and convex lenses in the camera Obscura with a telescope, just like a dozen years earlier Zahn already described in his beautifully illustrated book *Oculus Artificialis Teledioptricus Sive Telescopium* published in Würzburg in 1685.

Figure 6-94: The title page of the Zahn's book of the Ljubljana Franciscan Library (Zahn, 1696, 1:).

Zahn's work (1696) on the economically shaped mathematical-physics wonders of the world was bought by Ljubljana Franciscans and Škofja Loka Friars Minor Capuchin, as well as by the Stična monks. Zahn dedicated his first book that contained the first two parts to the Prince Joann Godefrid baron Guttenberg (Gottfried, 1645-1698), the Würzburg Bishop who got his position eleven years after the death of Johan Philipp Schönborn. Another book with the third part of Zahn's work was dedicated to Otto Philipp Guttenberg (1644 - 1723) the brother and personal adviser to that same already mentioned prince of Bamberg and Würzburg (Herbipolis). Just after the dedication, Zahn printed a giant pedigree of his patron. In the first book he indeed published Geocentric Ptolemy's picture of the world in double A3 format.[800] He drew orbs around the earth as a cosmos of individual planets. He followed a similar hierarchy of worlds in his further pictures.[801] Finally, he drew on the same picture all three cosmic systems of their major designers: Tycho, Ptolemy and Copernicus.[802] He then published a map of the lunar surface which looked like Riccioli's-Grimaldi's older lunar map.[803] Zahn immediately added a map of the Moon summarized by Jan Hevelius: that Moon looked quite like the earthy surface and somehow anthropomorphic. It was followed by a series of astrolabes with a table needed for providing correct results to their users.[804] Zahn also published a table of sunspots,[805] which he then sketched.[806] He dedicated a special illustration to the changes of the image of Saturn.[807] Zahn devoted two pages filled by images to both celestial hemispheres pictured with the data of Jan Hevelius.[808] Zahn already fully compensated the fear of empty of antique philosophers by the weight of air based on Boyle's experiments with a vacuum pump, Borelli's, Mariotte's and Du Hamel's ideas.[809]

At the beginning of the second book Zahn summarized Valvasor's description of the Cerknica lake. For the clarification of the causes of the annual changes of lake water levels, especially the November flood of the Cerknica Lake, Zahn quoted Kircher's *Mundus*, namely the third chapter of the fifth Kircher's book. Zahn also referred to chapters 46 and 47 in the Valvasor's fourth book.[810] Zahn plotted Valvasor's model as Zahn's figure no. 1.[811] Zahn imagined the model of the

interior of the earth and the winds completely based on Kircher's ideas. Zahn also provided an illustration.[812] He used Kircher's similar terminology so that Zahn's entitled his third part in the second book *Geocosmi sive Mundi Terrestris*. Zahn described the lake of Cerknica in the fifth chapter immediately after the other wonders of Kircher's and Strabo's collections, directly after Kircher's miraculous plant from Westphalia. After his notes on Valvasor, Zahn published a summary of Pliny's, Strabo's and Cornelius' description of volcanoes around Naples. Zahn then gave a description of the volcano in the Chinese province of Xansi, probably also borrowed from Kircher book China Illustrata of 1667. On the next page Zahn described the volcano Etna, and in the next section Zahn embarked on the occult features of the interior of the Earth,[813] of course again with Kircher's data.

Figure 6-95: Zahn's chapter on air and vacuum in the Ljubljana Franciscan Library (Zahn, 1696, 1:308).

Zahn dedicated his book to the Bishop Guttenberg of Würzburg and published a whole song in his honor. In his index of maters Zahn did not list many personalities, but he certainly did not forget to note the Jesuit Honorat Fabri.[814] Zahn sketched

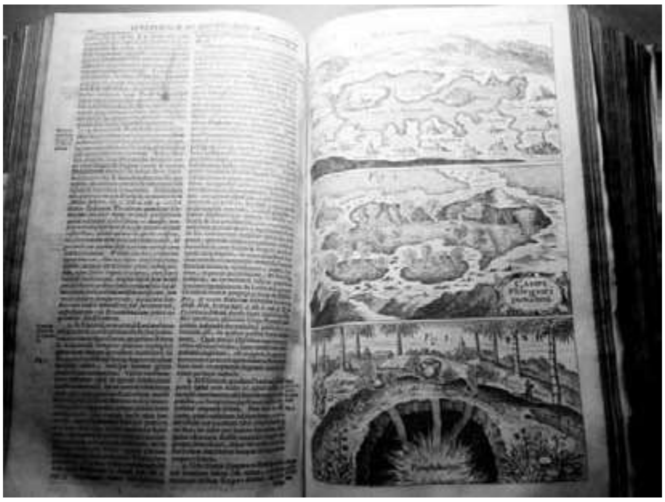

Figure 6-96: Zahn's sketch of Cerknica Lake on top right next to other natural sights (Zahn, 1696, 2:34

an eye,[815] refraction,[816] Camera Obscura[817] of closed-type like the modern cameras,[818] three guys using sighting technique to determine proportions of a dragon,[824] and a refraction of light on the surface of water.[819] Zahn wrote about the physical ratios of the eyepieces,[820] the types of optical tubes,[821] and *Lucerna Magica*.[822] He tabulated a combination of concave lenses[823] and the diameters of optical apertures by the researches of the Capuchin Rheita.[824] Zahn was interested in the Galileo's or the Dutch telescope,[825] the Bologna professor of mathematics Giovanni Antonio Magini's (Maginus, 1555-1617) device for measuring of convexity,[826] lens grinding devices,[827] microscope control screws.[828] Zahn used the apparent average movement of the sun in 1680 for the calculation of the horoscopes.[829] Zahn sketched the Sun, Earth and Jupiter[830] to be able to calculate the rotation period of Jupiter.[831] Besides

the regular camera,[832] Zahn drew a projection camera,[833] suspension lamp,[834] horoscopes,[835] parts of the microscope[836] and the inclined microscopes with lamp.[837] After four pages of appendixes Zahn published the alphabetical index of matter without surnames.

Zahn also published a similar hefty work on artificial optical devices nicknamed "artificial eyes"; the older copy (1685) of Ljubljana Augustinians had the individual chapters paginated separately and different images from the Nurnberg edition (1702), which was purchased by the Jesuits in Ljubljana four years after the printout. Both folio format books were bind into white leather, but Augustinian's book had a slightly softer binding leather.

In 1705, Beno Waldreich (Valterč, * Tyrol; OFMobs Before 1705; 30. 3. 1754 Novo Mesto) got completely New Book of Sebastian Dupasquier (* Around 1630; OFMconv; D. 1718). Dupasquier was a former Provincial of the Province of Saint Bonaventure. Waldreich was a definitor, general lector, provincial, general visitor of Tyrolean and Bavarian provinces. Between the years 1727–1728 he was lector of Philosophy in Novo Mesto. In the years 1731 – 1732 and 1739 he was a lector of theology in Trsat. In 1733 he was a lector of general studies in Ljubljana and magister of the novices. He was a relative of Anton Caharia (Zacharia) Waldtreich, a Ljubljana trader of Tyrol Genus.[838]

Dupasquier had retired as professor of theology. He denied the vacuum after reading Scotus and Aristotle. In the vacuum there is no resistance to the motions. So, the events in vacuum do not follow one another which makes vacuum impossible. The funny idea could be interpreted in the frames of the modern arrow of entropy which needs causality to provide the necessity of arrow of time moving forwards.

For Dupasquier, the dilution is not insertion of vacuum between the particles of substances, but it requires mixings of the air and the particles of substances.[839] To prove those ideas, Dupasquier mainly used the help of Scotus' works. Dupasquier refused Copernicus and Galileo. Dupasquier debunked them with the acts of the general inquisition from year 1666,[840] rather than with the arguments of reason or experience. Dupasquier likewise insisted on the antic four elements and refused the additional items of chemists and one sole substantial particle of atomists.[841]

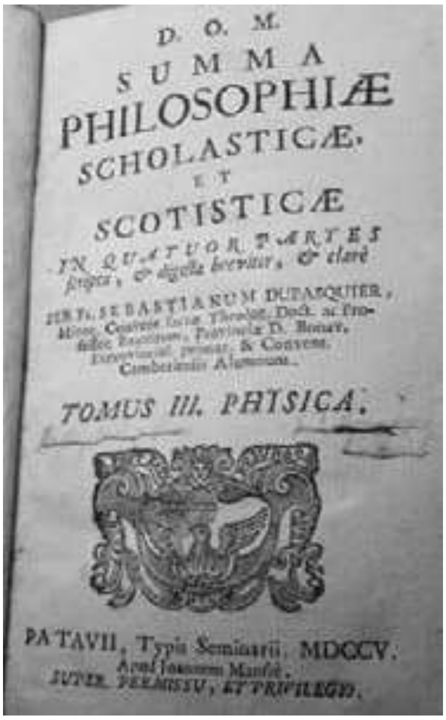

Figure 6-97: Title page of Dupasquier's third book with Ex Libris of Beno Waldreich in Ljubljana Franciscan library (Dupasquier, 1705, 3. part); F.

Škerpin acquired the academic natural history science of Trnava professor Laurentius Tapolcsányi and his student Ladislav Korlatköy. Tapolcsányi was a rector in Trnava between the years 1719 – 1721 and again just before his death. Tapolcsányi did not follow the sequences of narration of Aristotelian physics and other peripatetic books in three separately paginated parts of his book. Tapolcsányi's vacuum was not specifically highlighted in a separate paragraph. Tapolcsányi added fifty exam questions on the end of his book. Tapolcsányi's Vacuum was identified as supernatural, but movement in vacuum

In Ljubljana, Franciscans soon began to purchase books in German language, including a book of member of the Royal Society John Ray FRS (b. 1627; d. 1705) in the translation of Lutheran theologian Caspar Calvör (Calvoer, * 1650 Hildesheim; d. 1725 Clausthal) published in the year 1717. The translator added dozens of pages of details on vacuum pumps in footnotes below the line in the chapter about air.[843]

Figure 6-100: Pourchot's table of pictures presenting the distillation (Pourchot, 1730, 2: Table 6)

[843] Ray, 1717, 317.

The Capuchins of Škofja Loka, the Friars minor observants of Ljubljana and Rijeka friars purchased late edition of Pourchot's textbook. The Jesuits were certainly not his fans. For a quarter of century Edmund Pourchot (Edme Purchotius) was a Parisian domestic tutor of the nephew of leading Jansenist Pascal's friend Antoine Arnauld (1612 Paris-1694 Brussels) before Pourchot became the professor of philosophy at university of Paris and later got the honor of a rector seven times. He began to publish his lectures entitled *Institutio philosophica ad faciliorem veterum ac recentiorum philosophorum lectionem comparata* in four volumes in Paris in 1695. His first volume was initially devoted to logic, metaphysics and elements of geometry; the second to the general principles of physics (optics, mechanics); the third to cosmology and the natural sciences; the fourth to ethics and Exercitationes scholasticæ. The author then perfected this work until the end of his life, and there were several other editions during his lifetime and later with the title changed in the plural as *Institutiones philosophicæ*. In 1739 edition purchased in Carniola Edme Pourchot wrote about vacuum in the second volume of his work inside his General physics, which he finished with the seemingly occult phenomena among which he added sympathy, antipathy and Antiperistasis (ἀντί περίστασις).[844] But right there the leaves in the copy of the book in the library of Franciscans of Ljubljana are not cut, and so the book did not exactly inflame the fans among the Ljubljana Franciscans.[845] He crowned his description of motion in the vacuum[846] with an indication of experiments of Johan Christoph Sturm and the theologian Henry More (Heinrich Morus, 1614-1687) from Cambridge, with good illustrations and detailed descriptions of pumps.[847] All phenomena of fear of empty were attributed to the air pressure and Pourchot described Pascal's experiments. Next, Pourchot followed his ideas by a chapter dedicated to light, color and sunshine,[848] but Pourchot's electricity and magnetism did not get any specific chapter and neither did Pourchot provide any images about them. In his penultimate third book on special physics Pourchot narrated about astronomy with a fairly details focused on his presentation of Tycho's system, sketches with Cartesian vortexes in space[849] and biology. The Cartesian vortexes apparently show Pourchot's sympathies for Descartes, much like later Bošković's curve of forces have only been published by Bošković's advocates. Despite Descartes' denial of vacuum and Cartesian theological disputes with Arnauld, Pourchot was one of the most important proponents of Descartes' physics combined with the Parisian academic scholastics. Pourchot's books took the new philosophical spirits to Poland, as well as into Turkey or in Ljubljana.

The enthusiasm of the Ljubljana Franciscans about the Cartesian charms of the divine Paris has only escalated, therefore they also purchased the books of Regnault and of Pourchot's fellow at the Parisian University a member of the Parisian Academy Laurentius Duhan (* 1656 Chartres † 1726 Verdun), who lectured in philosophy in Sorbonne Collège de Plessis for over three decades. Of course, the general lector, definitor, several times guardian (custos) Avrelij Čeuko († 16. 5. 1746 Ljubljana) as a Ljubljana Franciscan lecturer in philosophy, purchased the latest issue of Duhan's philosophy in 1727. Duhan studied in Montaigu in the Vendée department in the Pays de la Loire region in western France, where they always hired two professors of philosophy. Among Duhan's students at Sorbonne-collège du Plessis was later distinguished Jean Denyse, the professor of philosophy at the prestigious collège de Montaigu at the University of Paris. The older edition of Duhan's philosophy arrived in Ljubljana Lyceum Library from Stična. It was printed in 1708 but left without bookplates and bind in brown leather, different from mostly white covers of Stična books. In a later edition (1715) it was read by Maribor Friars Minor Capuchins.

In his very popular book Duhan explained the vacuum in sophistic way popular before the Socrates's age by pointing the arguments for and against. In his introduction Duhan set forty-eight queries enumerated with Roman numbers. He put the puzzles about physics next to them with some interesting titles like:[850] *De Definitione Physices,*[851] *De Divisione corporis*[852] and *De Definitione Anima*.[853] Duhan proclaimed physics as the speculative science of natural bodies, which dealt with the causes of mixtures of bodies and elements. He followed Aristotle regarding the matter and shape as the basic characteristics of the body. Duhan defined nature as the principle and cause of the movement.[854] The natural bodies are divided into a simple and assembled.[855] After his logic, moral philosophy and metaphysics, the physics was the fourth and last part of the book[856] entitled *De Rebus Physicis*.[857] With his chosen examples, Duhan proved that physics is not perfectly absolutely true,[858] which was the agnostic position of the English antiquarian Thomas Baker's (1656-1740) *Reflections on Learning, showing the Insufficiency thereof in its several particulars, to evince the usefulness and necessity of Revelation*. The item was printed in London by A. Bosvile in 1699, and again in London in 1709-1710. It became very popular in Ljubljana and Zagreb Jesuit headquarters in the following decades culminating with the Cartesian Kazimir Bedeković Komorski and Josephus Mathias Engstler's *Tractatus de incertitudine scientiarum, recens ex italico latine redditus*, Zagrabiae: Cajetani Francisci Härtl, Anno 1759, Dum Assertiones ex universa Philosophia... Collegii Labaci. A member of the Parisian Academy Laurentius Duhan was certainly aware of the French translations of Baker's treatise of Nicolas Berger which were published in Paris in 1714, in Lyon in 1721 and in Amsterdam in 1715.

Despite the unambiguous following of Aristotle, Duhan also tackled a completely modern special physics. He especially highlighted the vacuum as an absolute real item, but without Duhan's indication of individual experiments.[859] Soon

afterwards the Jesuit Baron Anton Erberg of Dol manor promoted Jean Vincent's book against Cartesian interpretation of the vacuum in Vienna in 1730.[860]

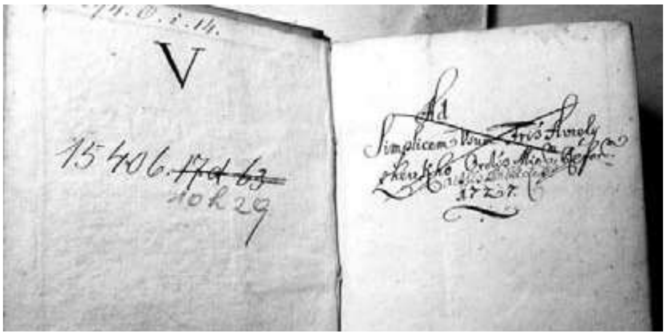

Figure 6-105: The crossed out proprietary entry of Aurelius Čeuko († 16. 5. 1746 Ljubljana) on the title page of Duhan's philosophy of Ljubljana Franciscans' library (FSLJ-17 D 63).

Duhan followed the Cartesian laws of movement[861] and various systems of the cosmos:[862] Ptolemy, Copernicus and Tycho. Copernicus can be defended (only) as a hypothesis, Duhan claimed, but Duhan did not deal specifically with Tycho and was not holding Copernican positions anyway.[863] Copernicans were still banished in Papal index. Duhan rejected the Ptolemy's system,[864] while Duhan only allowed Copernican ideas as the hypothesis.[865] The only remained was Tycho, whom in contrast with the rest, Duhan didn't even try to refuse.

Duhan listed the causes of tide,[866] described the nature of the light,[867] especially focusing the refraction,[868] and the nature of heat.[869]

Duhan discussed the endless divisibleness of the particles in a later Bošković's sense,[870] but, unfortunately, Duhan did not illustrate his ideas with sketches like the subsequent Bošković's fans. Duhan's vacuum was possible in absolute terms,[871] as allowed by God.[872] Unfortunately, Duhan mainly philosophized and did not mention Torricelli's and other experiments with barometers.[873] The description of heterogeneous bodies has finished Duhan's discussion on Vacuum.[874] He was interested in simple experimental lifting of heavy bodies,[875] which was to some extent the opposite of Aristotlians, with many traces of Galilean way of experimenting. Duhan first assumed that the vacuum was absolute possible.[876] He then set a series of assumptions that could be refused with the arguments like: the weight of the air is the real cause of movement. The presumption was quickly challenged by the great avalanche of doubts questioning even the description of the operation of the vacuum pump and mercury in the barometer.[877]

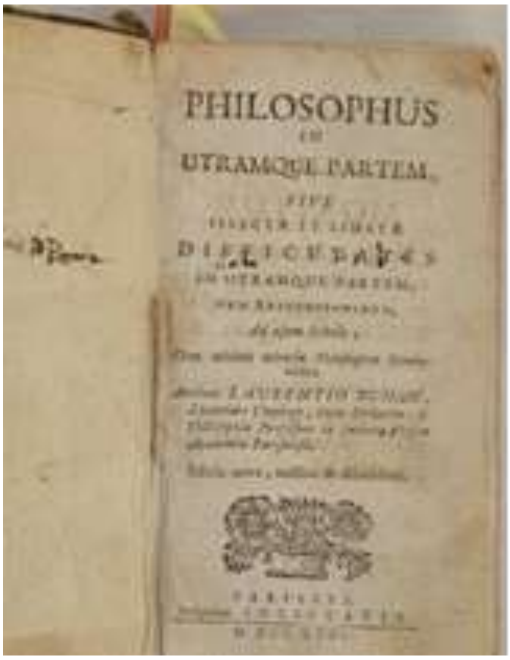

Figure 6-106: The title page of Duhan's philosophy in Ljubljana Franciscans' library (Duhan, 1726).

Duhan participated in the debates on the Newtonian oblate (oblatum) versus Cassini's oblong (oblongum) earth focused on the terrestrial emission of magnetic flows (Efluvium) unaffected by gravity.[878] By Peraldi (Guilelmus Peraldus) and

Descartes' model, Duhan has considered the Cartesian vortexes of the ether as the explanation of the free-falling under the sole influence of gravity.[879] Even so, he had some doubts in Descartes.[880]

Duhan's light was a pressure[881] in Cartesian sense, while Duhan's law of reflection was also explained by Descartes.[882] He was interested in nature of the colors. He no longer had a heat as a common property of a body in peripatetic sense.[883] The heat should result from individual reflections and changes in light.[884] The heat should consist of swirling and expansion movements of the invisible small particles.[885] Duhan's cold is supposed to be the absence of heat movement,[886] which was a modern enough assumption.

Duhan produced his Batavian tears by distillation,[887] like other similar chemical compounds. Duhan was especially interested in glass drop (Batavia Tear, *Lachryma Batavica*) obtained by dropping a bit of incandescent glass into a bucket of colder water which Hooke illustrated in his *Micrographia* in 1665, and the Cartesian Jacques Rohault pictured and tried to explain in his *Traité de physique* in 1671.[888] Fragments of glass, investigated by the secretary and founding member of Rouen Academy the surgeon Claude-Nicolas Le Cat from the Rouen Academy, were supposed causes of explosions and eruptions of volcanos.

Duhan finally searched the properties of the magnets.[889] Magnetism was traditionally explained with double force-motion, direct and lateral,[890] as *De Virtute Magnetica*[891] with which Duhan finished his book.

In 1737 the professor of theology Anselmus Schnell (OSB; D. 1751 Weingarten), the Benedictine Abbot from Weingarten, proclaimed a vacuum for supernatural God's creation. He saved the honor of Aristotle, who refused vacuum, but

the experiments of past decades have placed the peripatetic on thin ice.[892]

The Jesuit Cartesian Noël Regnault (b. 1683; d. 1762) taught in Amsterdam and Paris. His works were probably used as textbooks at the Jesuit college and at the Franciscan Monastery in Ljubljana where they obtained three different Latin promotions of Regnault's works published by the Jesuits of Graz. Regnault was also very popular in Trnava University of Andreas Jaszlinski. Regnault favored Descartes over Newton as the French nationalist, but the Central-European Jesuits without French national feelings promoted their co-brother Jesuit Regnault anyway.

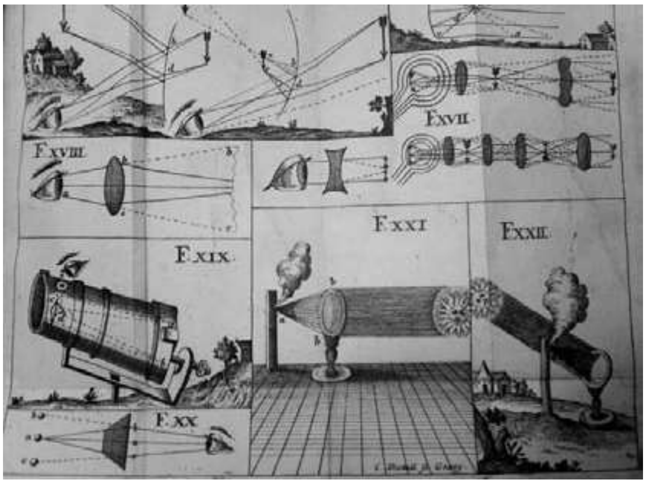

Figure 6-109: Telescopes in Regnault's work at Ljubljana Franciscans' library (Regnault, 1736, table of figures 1).

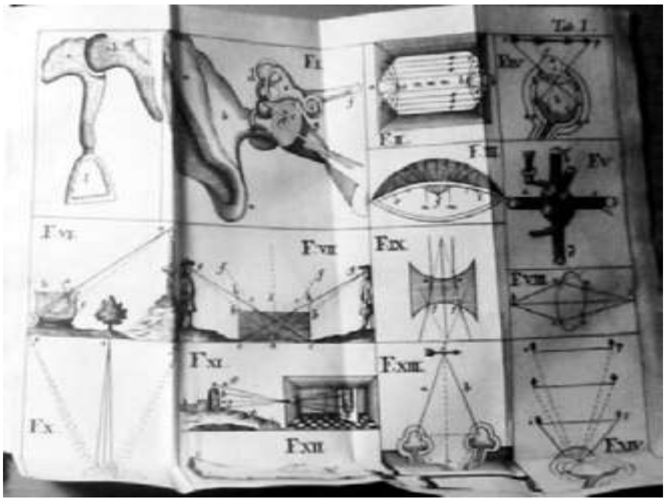

Figure 6-110: Optics in Regnault's work at Ljubljana Franciscans' library (Regnault, 1736, table of Figures 2).

[892] Schnell, 1737, 157.

In 1729, in his popular book on ancient Foundations of modern physics Regnault dealt with the concept of temperature and heat.[893] He described porosity, vacuum, magnets, gravity, air, hydrostatics, cold, heat, fermentation, underground cold and sea.[894] He quoted Plato's Timaeus, Gassendi's and Lucretius' description of the atoms and treated the vacuum.[895] He has even published the funny time-machine interviews in which the thinkers of different times have appeared: Aristotle, Aristarchus, Descartes, Kircher, Albertus Magnus and modern physicists.[896] The idea of such debates was of course already Plato's and Galileo's.

Regnault has dealt with numerous experiments, including Boyle's and Torricelli's. He described Galileo's and Kircher's opinion on "fear of empty". He then mentioned experiments with the pressure of Pascal, Mariotte and Boyle, and explained the differences between fire and cold.[897] Regnault did not publish sketches and images that would also beautifully illustrate the interpretation of many experiments. In the "Dialogues" we follow Regnault's conversation in the letters between Aristus and Eudoxus according to Galilean examples. Similar discussion was published at the same time by Ingolstadt Professor Joseph Mangold (b. 1716; d. 1787), who described more specifically the experiments with pumps,[898] but he also avoided drawings; Mangold soon became the primary Bavarian defender of Bošković's ideas.

Škerpin seems to be extremely interested in early debates about vacuum possibilities which were very popular after Torricelli's barometer became available. Škerpin acquired the posthumously published textbook of the Franciscan Parisian professor Claudio Frassen (b. 1620 by Peronna (Péronnas) of east France; OFM; D. 1711 Paris) of 1726. Frassen had distinguished between the common and philosophical vacuum in the spirit of his times. Frassen believed in the real existence of the vacuum together with Gassendi despite of the criticism of Descartes or Rohault. Frassen listed

the relevant experiments which checked the behaviour of vacuum. He was interested in the potentially possible supposed air above the atmosphere of Earth and tried to solve the main problem of the vacuum technique of his times, namely the possibilities for the flight of the angels through empty space. He described the experiments with mercury, probably the one from Idrija Mine in Carniola, and became very interested in Boyle's air pump with its recipients and glass vessels. Frassen researched the condensation and thinning of substances. Frassen tried to press the air and most of all he liked to conserve the fruits, flowers, meat, and similar devices in vacuum which he considered to have almost divine properties.[899] In that way, the vacuum transformed from the persona non grata of horror vacui into the divine glorified subject. There were many of his contemporaries who shared his opinion believing that Aristotle reasonably proved the impossibility of vacuum, but the omnipotent God had the abilities to create it anyway.

Figure 6-111: The title page of Frassen's philosophy at Ljubljana Franciscans' library (Frassen, 1686).

[899] Claudio Frassen, José Maria Ribeiro da Fonseca, *Philosophiae academicae,* Tolosae: Guillelmo Ludovico Colomer, 1686; Reprint: *Philosophiae academicae, 1 logicam et metaphysicam completens 2 primam et secundam partes physicae impertarium completens 3 tertiam partem physicam completens 4 moralem scientiam completens… recens in lucem edita corrector & enendatior… Josephi Mariae ab Ebora…* Romae: Rocchi Bernabe (FSLJ-13 c 28), 1726, 2: pp. 274, 327, 328, 334, 335, 336, 342, 343, 344.

The new bettered edition of Frassen's masterpiece was provided by José Maria Ribeiro Fonseca who arrived in Rome as a youngster to become a Franciscan in Rome on 8 December 1712, few months after Frassen passed away.

Figure 6-112: Copernican system in Frassen's philosophy at Ljubljana Franciscans' library (Frassen, 1686, 466).

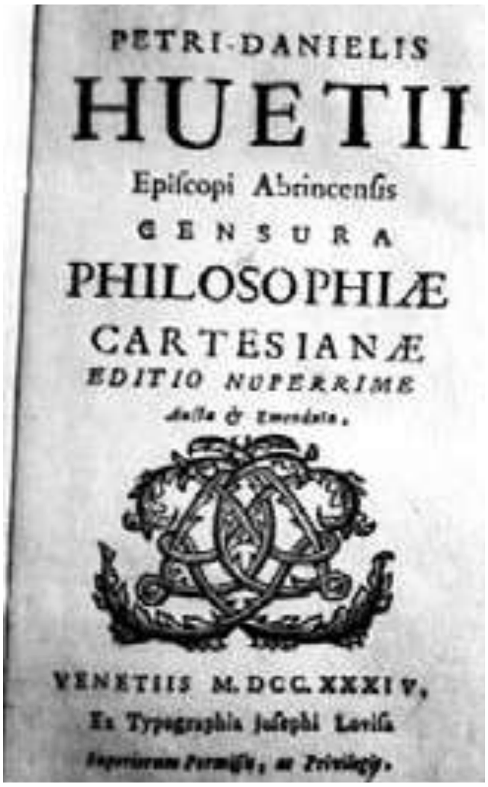

Figure 6-113: The title page of the Huetius' book.

Ludwig von Gallenfels (Golnik, baptized Johann Jakob on 14. 12. 1662; OFMobs; d. 22. 2. 1728 Kamnik) used his forty years older edition of Frassen's book issued when he was a graduate student. Ludwig von Gallenfels was a son of the owner of manor Golnik and the governor of Bled

Johan Andreas Gallenfels and his wife Anna Maria Kuschlan from Zablate manor by Brezovica by Ljubljana. Ludwig's godfather was Andreas baron Trilleck, the grandfather of Jurij Andrej Triller Count Trilek (1663-1701) who owned Lana's book of vacuum balloons published in 1670 while Škerpin got half of a century later edition of Lana's work. Ludwig Gallenfels certainly knew Lana's ideas which influenced Ludwig Gallenfels's opinions about the reality of vacuum. Ludwig Gallenfels became the Ljubljana Franciscan lector and then provincial of Bosnian Croatian province in 1702-1704. As a lector, Ludwig Gallenfels used the book of Frassen to learn about the differences between a common and philosophical vacuum.

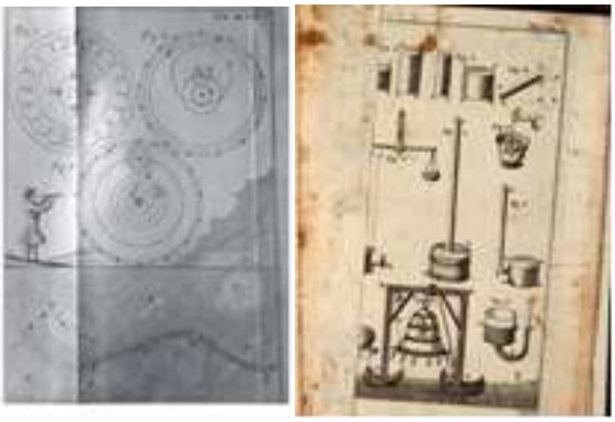

Figure 6-114: Images of solar system and measurement of weight of air from the second part of the Ferrari's philosophy with physics (Ferrari da Monza, 1754, 2: Tab 1).

After Gallenfels passed away, the Ljubljana Franciscan rector Scotus's follower Hieronim Markilič (1712–1790) commented on Frassen's description of the vacuum experiments in the older previous Gallenfels' edition of 1686, which means that Škerpin acquired a newer edition of 1726 after Markilič wrote his manuscript notes. In terms of vacuum testing, Markilič recommended "Our Pater Frassen".[900] The book of French Franciscan Frassen was the one used as a textbook by both Gallenfels and his half a century younger colleague anti-cartesian Markilič. Markilič described his vacuum in his comments on fourth Aristotle's book [901] by describing Gassendi's atoms of various forms and Descartes' opposition to the vacuum.[902] The fashionable production of a vacuum in the pipe (Fistula) put the lie to fear of vacuum,[903] even if vacuum still provided the obstacles for the movement of Angels and Lucifer himself in a vacuum[904] for the sake of a slight resistance of any movement in the vacuum[905] until the rocket propulsion saved those problems of travelling angels. In his comments on Aristotle's formation and decay, Markilič briefly summarized the dilution of the substance and specifically described the air as one of the basic subjects of meteorological phenomena.[906]

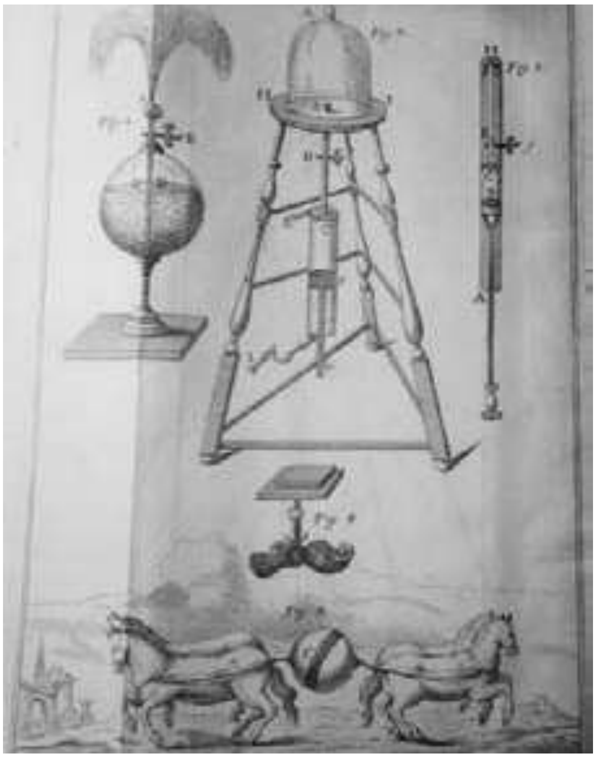

Figure 6-115: Images of vacuum pumps and experiment with Magdeburg hemispheres in Regensburg from the second part of the Ferrari's philosophy with physics (Ferrari da Monza, 1754, 2: Tab 2).

Peter Daniel Huetius (Pierre Huet, b. 1630 Caen; d. 1721) the Bishop of Abrincensis (Avranches) in Normandy used to be among the most talented Frenchmen of his generation. His criticism of Cartesians was republished posthumously in Venice with a quote of the Descartes' jar full of wine, which was still not completely empty even

after a noble gulped down the precious liquid down his throat.[907] Similarly, the Köln Jesuit University professor of philosophy the Cartesian Mathia Heimbach (* 1666; SJ; D. 1747) imagined thirteen years later, when he swore on the unnatural vacuum, Cartesians and residue of the subtle substance in the barometer.[908] The Franciscans of Ljubljana used both books, but they probably soon preferred Anti-Cartesian and anti-Jesuitical stances.

Figure 6-116: Figure 2 explained Hauksbee's measurement of the weight of air at the second part of Ferrari's philosophy with physics (Ferrari's da Monza, 1754, 2: Tab 3 and p. 2:81).

Škerpin also bought his contemporaries' physics, among them the modernized peripatetic discussion of the Franciscan Scotus' fan Josef Anton Ferrari from Monza (Giuseppe de Modoetia, D. 1776). Ferrari pictured many barometers and drew strong youngsters trying to weight the vacuum. He was also interested in the newly invented steam engines which slowly penetrated from industrially more advanced England into European coastlands. He did not forget to show the famous Magdeburg vacuum experiment with horses which was performed in Regensburg. The inventor Otto Guericke gave considerable credit to the Ljubljana prince Janez Vajkard Auersperg who attended the Regensburg diet as the informal prime minister of the Habsburg Emperor. Ferrari asked himself about the vacuum and answered in the manner of Gassendi, Boyle, and the famous Newton. Ferrari had his hardest time to figure out if the vacuum could conserve and preserve itself. He resolved that fundamental question with Torricelli's atomism although he also cited the Cartesian critiques of existences of void spaces. The main supporter of the atomic theory was certainly a Roman Lucretius, and Ferrari relied on him by experimenting with Magdeburg vacuum hemispheres.[909] Ferrari became an established researcher of barometers. Joseph Anton Ferrari's group of pictures VII at the end of the book has barometers in the first picture, as well as on the second and third figures of the fourth group. In the second figure of group III he drew nice strong youngsters, who "weigh" the vacuum and then embarked on steam engines. In group II he had a picture 3 with vacuum pumps and a Magdeburg experiment with horses in Figure 5 borrowed from Du Hamel's book, which was also purchased by the Ljubljana Jesuits.

Figure 6-117: Figure 1 with barometers, Figure 2 with Pascal's experiment and figure 4 showing the lifting of water by vacuum pump from the second part of the Ferrari's philosophy with physics (Ferrari da Monza, 1754, 2: Tab 4 and pp. 2: 83, 84).

ARTICULUS PRIMUS.

Figure 6-123: Copernicus system of Locherer in Ljubljana Franciscans' library (Locherer, 1740, 4:56 (with the permission of Dr. Miran Špelič OMF)).

Of course, the Ljubljana Franciscans mainly trusted their religious co-brothers on the philosophical issues of the vacuum. That's why Škerpin bought the Venetian peripatetic physics of Spanish Franciscans Petrus a S. Catharina (Pedro de Santa Catalina, OFM) and Thomas a S. Joseph (Fr. Thoma a Sancto Ioseph) from Franciscan Observant Provinces of St. Joseph of barefoot (Discalceatorum, Ordo Fratrum Minorum Discalceatorum o Alcantarinorum / O.F.M. Disc. / O.F.M. Alc.) and Peripatetic philosophy of Italian Antonio Ferrari from Monza. The Ljubljana Franciscans had two copies of Petrus a S. Catharina's course, since they had already purchased the same issue printed in 1697 before Škerpin brought in the newer version. Petrus a S. Catharina described his vacuum on dozens pages of a small format.[910] Despite of dubious experiment with a vacuum, God can create and even allow angels to fly through it, and Petrus a S. Catharina has attributed the similar courage to the animals. The local movement in the vacuum is a miracle because the vacuum has no location as claimed already by Benedictus Valentin Pererius.[911]

Škerpin also bought a powerful Scotus' philosophy with the physics of his religious co-brother Alipius Locherer (OFMobs), the general lecturer and definitor of the Austrian province. Locherer still relied on the old scholastic grips. However, Locherer's Aristotelian eight physics books shrunk into seven, where the vacuum was dealt at the end of sixth book. He went so far as to refuse Descartes and with him Locherer declined whole Copernican system with Galileo and Kepler included. Locherer quoted the Italian poet Alessandro Tassoni. Even Tycho Brahe and William Gilbert were not sufficiently good for Locherer as he preferred to cite Antoine Goudin and Guérinois.[912] Ljubljana Franciscans also liked to read Guérinois' books. Locherer relied on (Compton) Carleton's work, which was also read by Ljubljana Franciscans; Compton Carleton devoted his book to Bavarian electoral prince Maximilian II Emanuel (b. 1662; d. 1726) just like Locherer a half-century after him dedicated his work to Maximilian's morganatic son Emanuel Francois Joseph count of Bavière marquise Villacerf. The pleased Emanuel repaid Locherer's dedication with some golden coins.[913] Cardano and Girolamo Francastorio (Hieronymus Fracastorius, b. 1478 Verona; d. 1553 Calfi (Alfi) by Verona) have demonstrated the supposed natural fear of the vacuum, which the Cartesians wrongly supported but God can still create a vacuum just as God can destroy all between heaven and earth of naughty disobedient

infidels.[914] Locherer attributed the Torricellian experiment of 1643 to the peripatetic Jesuit George de Rhodes (1597-1661) and to the researches of Valeriano Magni in conjunction with Bernard Sannig (OFM) whose books were also read by Ljubljana Franciscans, but Magni's visual evidence of vacuum did not fully convince Locherer who preferred to believe Cornaeus and Gassendi.[915]

Figure 6-124: Supplementary cover image of Sannig's book (Sannig, 1684, 1) and Sannig's sketch of Tycho's and Ptolemy's system in the Ljubljana Franciscans' library (Sannig, 1684, 2: 259); F

The Bohemian Bernard Sannig (b. 1637; OFM; D. 1704 Znojm) was a minister of the provincial of the province of Bohemia, Silesia and Moravia in Prague during many years. In 1676 as the Visitor of Province of St. Ladislav he also visited the monasteries of Ormož, Trsat and Zagreb. He was a professor of sacred canons at the emperor Karl's convent of Sanctæ Mariæ ad Nives (Our Lady of the Snows, Panny Marie Sněžné) near Jungmann Square in Prague, Minister of the Bohemian province and former Cismontane general commissioner in Prague. He dedicated his immense textbook of Scotus' philosophy to the main members of the reigning Habsburg imperial family with Leopold I included at the first place to receive as much of their pleasant support as possible. In the beginning, he listed a few dozen pages of Franciscan theological and philosophical writers alphabetically arranged by their names and even surnames. Unfortunately, he has probably considered only his own reformed branch of the Friars minors with Roger Bacon and Ockham, while he neglected the Minim Mersenne or the Capuchin Valeriano Magni or Anton Maria Schyrl Rheita. We miss of course also the Strict Observant Fortuno Brixianus, who was born after the printout of the Sannig's book. The second physical part of the book with independent pagination was dedicated to the prince-bishop of Bratislava Frančišek Louis, while the third part with meteorology, geography and metaphysics was dedicated to his general secretary, Peter Marino Sormann from Milan. The physical part was divided into four tractates. In next to last tractate in the 15th *Distinctio* he described the puzzles of vacuum. Unfortunately, he considered for vacuumists rather unfavorable habit of these days and he devoted his rich illustrations only to the winds in meteorology, and above all he decorated his chapters which explained astronomy and the sundials. There he set with his whole heart on the lost Ptolemy's side, even if the table of heights of the sun for the needs of gnomons were summed up by the main Tycho's supporter the Jesuit Clavius.[916] So much more he wrote about the vacuums. He introduced four vacuum observations: the attraction of smooth pressed surfaces, the barometer in water, the movement of the planets and the flame of the candles in a closed tube. He rejected them one by another. He then embarked on vacuum experiments of the Capuchin Valerio Magni with a brief mention of Torricellian achievements and rejected them too. As usual, he then introduced his *Deus Ex Machina*, the creator itself, who is naturally almighty and easily creates an otherwise impossible vacuum. Scotus' rejection of movement in the vacuum was supported by Mastrius (Barthol Mastrio de Meldula OFMconv),

[914] Locherer, 1740, 2:473 right column.

Poncius (Joannes Poncius OFM), Ruvi(us) and D. Thomas, perhaps Petrus Thomas OFM, whom Sannig noted otherwhere. Sannig opposed Albertus (Magni), Raffaello Aversa (b. 1598; d. 1657), Gregorio Bencio Ariminensi (Gregor Arimin Nenzi), Burlaeus (Walter Burley) or Charles Egide (Gilles) Duhan de Jandun (b. 1685 Jandun in Campagne; d. 1746 Berlin). Scotus' successive continuous movement in the vacuum was supported among others by Columbus (Bonaventura Columbo OFM), Mastrius (Maistrio) and Belluto (Bonaventura Belluto Catanensi OFM) against the ideas of Averro(es) and his editor Agostino Nifo (Svessan, Suessan (* ca. 1469/1473 Sessa Aurunca in Italy; d. 1538 Aurunca).[917] Of course, all Scotus' supporters were *Nostrum (Ours)*, therefore the Franciscans, while their opponents were outside their order. In the chapter about the air he did not add comments on the vacuum except the ancient findings of the rarefied air on the Olympus,[918] which was much scarcer than two decades older numerous examples of Sannig's religious co-brother Sichen.

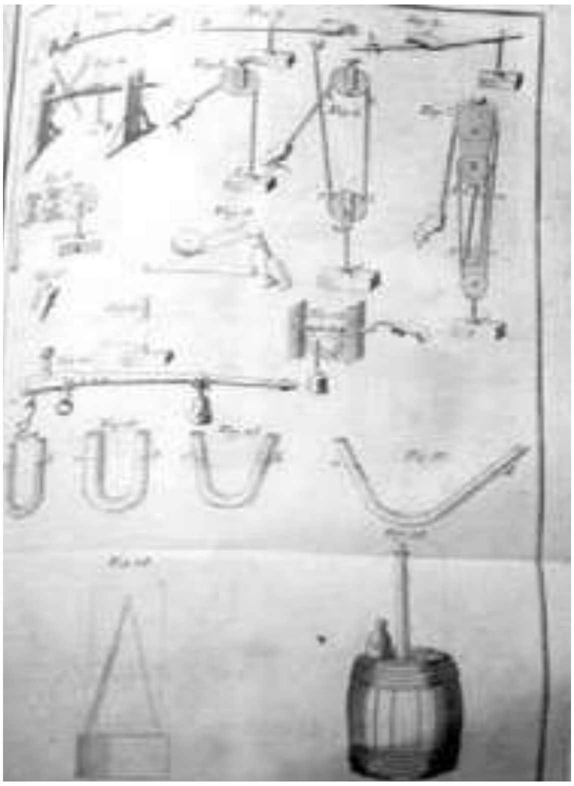

Figure 6-125: The first table of images with mechanics and hydrostatics in Cartier's work at Ljubljana Franciscans' library (Cartier, 1756,table 1).

In 1756 the Benedictine Gallo Cartier (Gallus) published his overview through all the fields of philosophy in a gigantic book, which was bought by the curator of Ljubljana Franciscans, the provincial elected twice, visitor of Bohemian and Slavonian province Vincent Marjašič (OFM; d. 13. 1. 1770 Kamnik). Cartier mostly tested Gassendi's ideas in the light of the vacuum and noted that the vacuum was possible, in contrast to the Cartesians.[919]

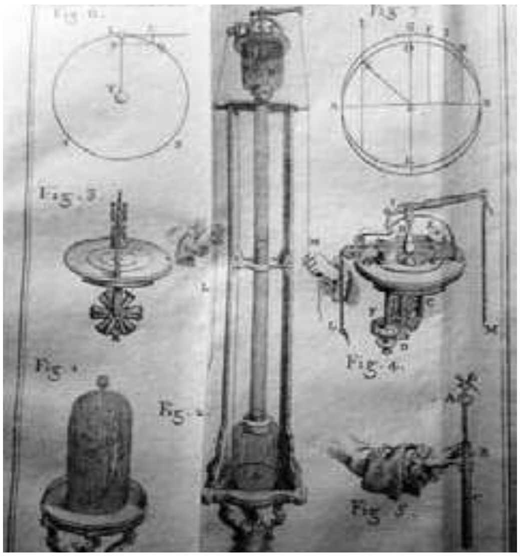

Figure 6-133: Experiments with Nollet's vacuum pump in the Library Franciscan Monastery in Ljubljana (Nollet, 1755, table of figures 1

The Ljubljana Franciscans used the books of Gruber's professor and a close Bošković's associate the Jesuit Karl Scherffer, whose works were also read at the domestic libraries of baron Erberg and Gruber's private student Žiga Zois. In 1749 and 1750 Scherffer was professor of mathematics and head of the Graz Observatory, and then a professor of mathematics with physics in Vienna. In 1763, the Archbishop of Trnava officially proclaimed the new Scherffer's book on Bošković's Physics for the textbook in Trnava. In that time, Bošković's ideas of physics prevailed among the Ljubljana Jesuits. At the end of the first part of the book, Scherffer published 155 images in unnumbered groups. In the last group, in Figure 138, he described the reducing the sound pressure of ringing tone in the vacuum. Figure 138 has shown a barometer, a picture 118 presented siphon, and pictures 101-105 illustrated a hydrostatic paradox.[920] In the reprinted textbook, which was immediately purchased by the Ljubljana Franciscans, Scherffer sketched vacuum experiments, cross-section of the karst hill and the cross-section of the air gun.[921] He praised Guericke's, Boyle's, Hauksbee's and Leupold's pumps, but sketched Nollet's accomplishment with increased images of valves.[922] He described Halley's interpretations of experiments from the academy in Florence,[923] Torricelli's baroscope[924] and the formation of air (gases) from other substances after the experiments of Johann Theodor Eller (1689-1760 Berlin) in 1745 at the Berlin Academy and of Musschenbroek.[925] Eller was a personal physician of the king and director of the physics section of Berliner academy. According to Hales, Scherffer calculated air density, absorption and gasification in Boyle's pump (*Antlia Pneumatica*, Αντλία Πνευματικά).[926] According to Boyle, Scherffer described the spread of electricity through the vacuum.[927] Besides the air and water vortices, he summed up Musschenbroek's paintings and Bošković's description of the Roman whirlwind from the year 1749[928] which was among the first Bošković's successes.

Figure 6-140: Nollet's vacuum pump at Ljubljana Franciscans' library (Nollet, 1751, Tom 2, table I Lesson 8).

Franklin's (and therefore also Scherffer's) opponent Nollet has enabled the Ljubljana Franciscans to read one of the most modern experimental manuals full of experiments with vacuum technics of 18th Century. Exceptionally, the Ljubljana Franciscans selected in addition to a two-part French edition of 1744 also the four-part Italian Venetian edition of 1751 with its last fourth part printed previously in 1749.The French edition of Nollet's work bound in reinforced cowhide brown leather was used by Ivo Bonelli (OFM; d. 22. 9. 1809 Ljubljana), the Italian issue bound in pigskin was used by the procurator and Ljubljana lector of philosophy Vincent Marjašič (Mariaschitz). Both must have been particularly impressed by the tenth and eleventh experiments of the second part of the third book with animals and fish in the vacuum.[929] The pater Ivo Bonelli was chaplain, a priest of the Tridentine diocese and the assistant professor (Suplent) of mathematics at the University of Innsbruck. He died of the fever which he caught when he gave the Sacrament of Anointing of the Sick to the French soldiers at the hospital at the time of the Illyrian provinces.

[929] Franciscans of Ljubljana diary, 1658/1660 – 1828, year 1766, folio 9; Nollet, 1751, 3:191-195, X lezione tavola 1-6, XI lezione Tavola 1-2, 4.

In his second book, Nollet reported on the behavior of the water in the vacuum.[930] He believed in a small compressibility of water without knowing of Herbert and Ambschell's experiments in Vienna and Ljubljana.

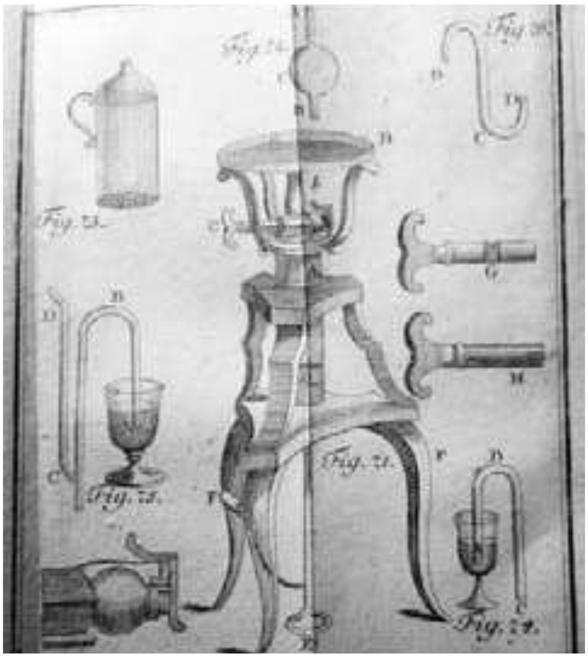

Figure 6-141: De le Fond's vacuum pump at Ljubljana Franciscans' library (Fond, 1785, table of figures 13).

[930] Nollet, 1751, 2:97, VI lezione Tavola 1.

The Ljubljana Franciscans bought the book of Nollet's Parisian successor in the chair of experimental physics at the Collège Louis le Grand Sigaud de la Fond in the German translation of 1785, where he served his readers with first-class illustrated vacuum experiments at the beginning of the book. He supported them with a well-founded history of Guericke's and other achievements.

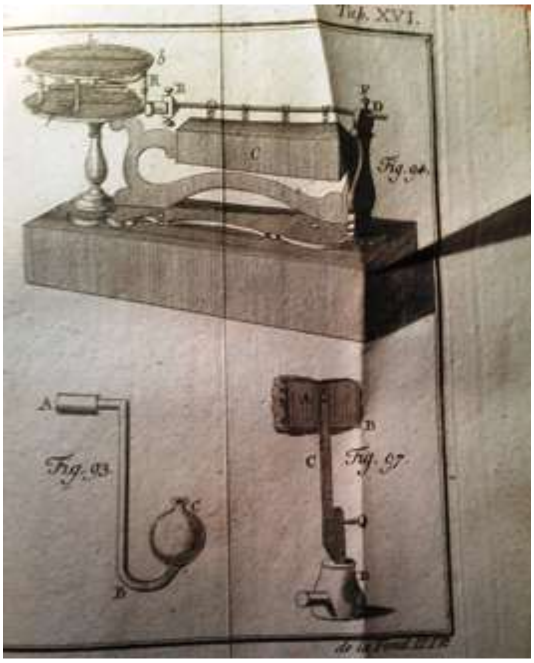

Figure 6-144: De le Fond's experiments at Ljubljana Franciscans' library (Fond, 1785, table of pictures 16).

The Frenchman of the order of Minims at Roman church of the Santissima Trinità dei Monti (La Trinité-des-Monts) Jacquier taught as the Roman Lyceum (today's University *La Sapienza* in Rome) after the ban of the Jesuits in 1773. Together with his religious co-brother Seur he published a commented translation of Newton Principles in Geneva in 1739-1742. It was also used by Novo Mesto Franciscans. Jacquier has been lecturing physics in Turin since 1745, and since 1763 he has taught physics and mathematics the duke of Parma. He also lectured in the City Roman College of the *propaganda Fide* established as the support of missionary activities in 1622. It was related with Inquisition[931] but not that much scary as it mostly cared about the missionaries. Jacquier translated whole Taylor's book into Italian language: he also relied on Newton ideas. He published a physical textbook for students of theology, which was reprinted by Graz Jesuits (1766) and was used for the courses of Jesuit philosophical studies. Three years after the printout, in 1765 the last two parts with special physics and mathematics were purchased by Ljubljana Franciscans. Only two of its three volumes are preserved without logic and general physics. After "General physics" with mechanics, Jacquier in the second part of "Special Physics" published the chapter (*Sectio*) on fluid(s), Light with Fire (II), astronomy (III) and Geography (IV). In section of the fluids he described air and summed up Torricelli's experiments with barometers with vacuum pumps included .[932] As an enthusiastic Frenchman he specifically praised Pascal's vacuum experiments.[933] The book was complemented by mostly geometric less attractive sketches. He used Newton's law of attraction, while he mostly ignored Bošković's supplementation at small distances. Jacquier's Letters about Hydrostatics were evaluated in the Venice physiocratic newsletter, which was also read by Ljubljana natives.[934]

Jan Ivanchich (Ján) and Antal Reviczký described many uses of mathematics in the spirit of the Maria Therese's Reform. Ivanchich studied at the Jesuitical Universities of Vienna and Trnava. Between 1755-1761 he taught philosophy at the

University of Trnava, and later became a professor of theology at the University of Vienna. In 1770 he became Abbot in Trnava (Nagyszombat). With the group of Trnava professors, he departed from scholastic philosophy and developed Regnault's Cartesian theory after the first Theresian reforms announced in 1753. He wrote several philosophical works, a textbook of physics and an optical dissertation.

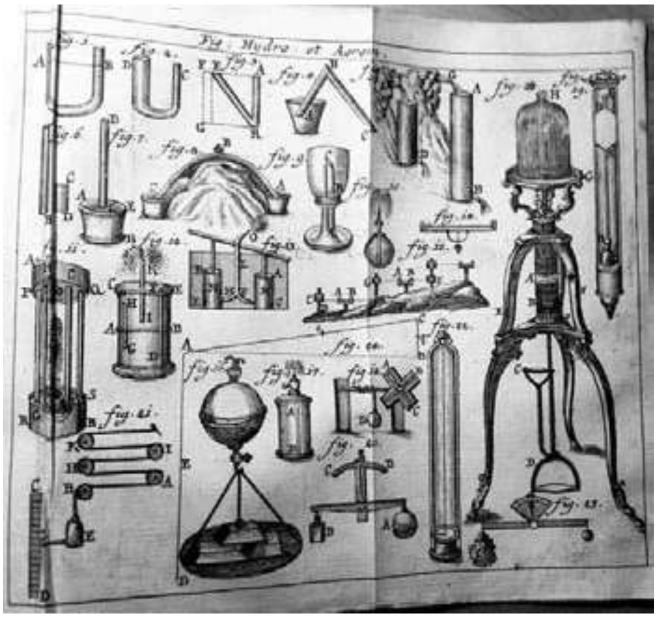

Figure 6-147: Weighing of force which holds together the Magdeburg hemispheres and Vacuum pump of Trnava Jesuits From Year 1752 in Ljubljana Franciscan library (Jesuits of Trnava (Ivanchich and Antal Reviczký), 1752, Images on the end of book, hydrodynamics and aerodynamics, Figures 16 and 24); F.

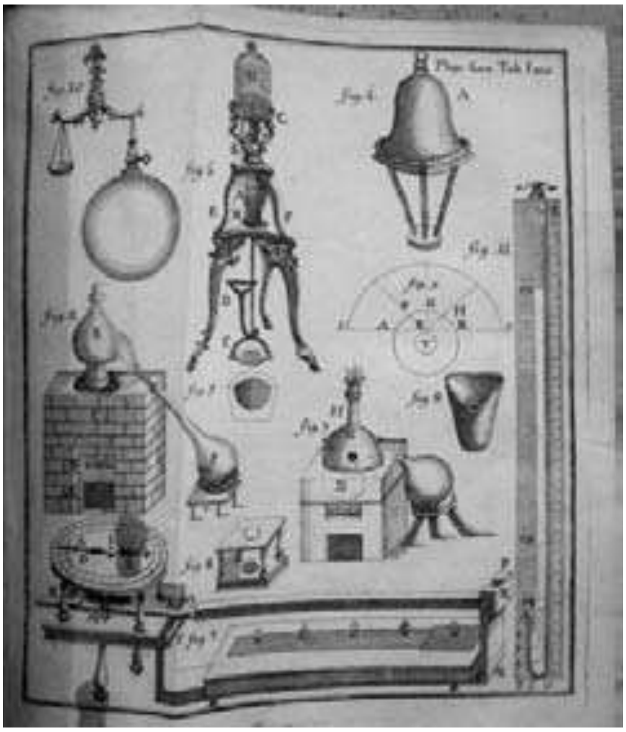

Figure 6-148: Weighing of force pressing on vacuum and vacuum pump in Jaszlinszki's general physics in Ljubljana Franciscan library (Jaszlinszky, 1756, First table of images on the end of General Physics, Figures 10 and 6); F.

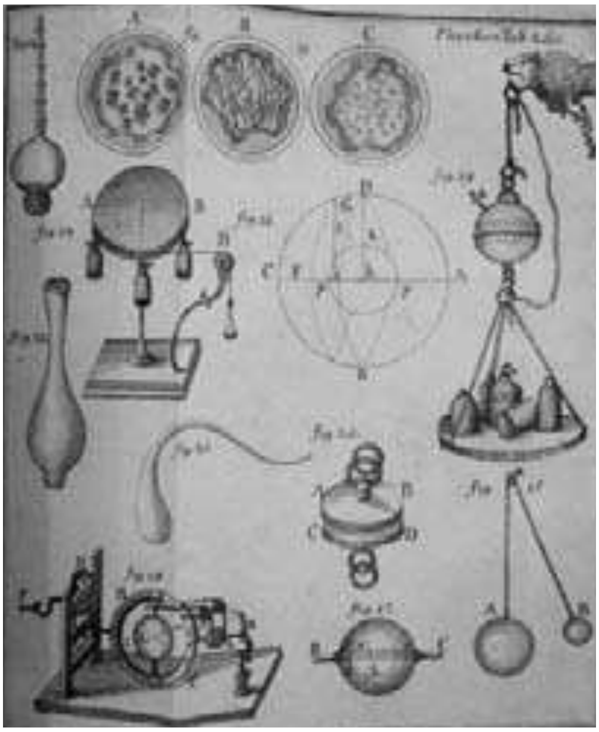

Figure 6-149: Pressed Guericke's Magdeburg hemispheres and electric glimmering of vacuum containers in Jaszlinszki's general physics in Ljubljana Franciscan library (Jaszlinszky, 1756, Second table of images on end of general physics, figures 19 and 17); F.

Figure 6-150: Jaszlinszky's experiments with magnetic field lines (Jaszlinszky, 1756, table of figures 6)

The Cartesian Reviczký was Ivanchich's colleague at the University of Trnava. In 1757 and 1758 he published Elementa philosophia naturalis there. In the second part of the book, he dealt with specific (experimental) physics and described the movement of animals according to Descartes and Galileo's friend Giovanni Alfonso Borelli (* 1608; † 1679).

Ivanchich and Reviczký knew from Galileo's researches that the vacuum can raise water 32 feet high. They determined the height of atmosphere and for further reading they recommended mainly the works of their religious co-brothers Jesuits: Joseph Falck's (d. 1737) Mundus Aspectabilis Philosophice Consideratus from year 1740, which Ljubljana Jesuits purchased seven years after printout, the books of French Jesuit Milles De Chales' (Dechales) and the Jesuit Lana from Brescia. Ivanchich and Trnava Jesuits researched the elastic options of air compressed in container. Lana's described it in the second part of his famous book, which Ljubljana Franciscans also had.

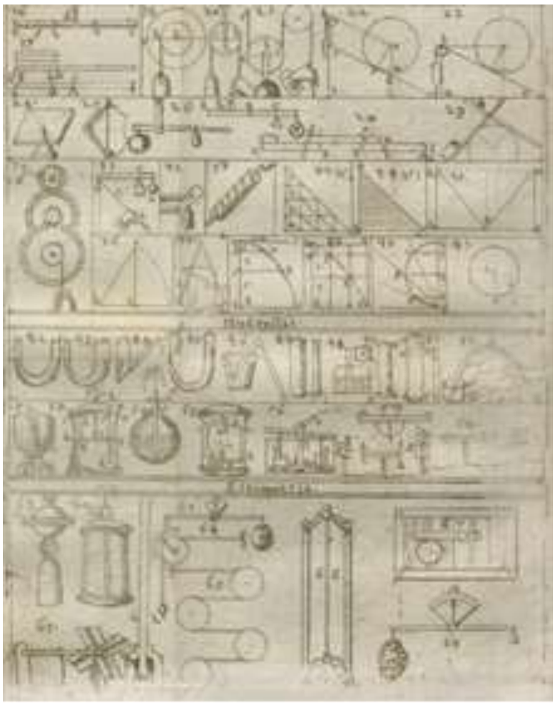

Figure 6-151: Vacuum pump of Trnava Jesuits (Ivanchich, Reviczký) of the year 1752 (Jesuits of Trnava (Ivanchich, Reviczký, Jesuit professor of mathematics in Freiburg and Dillingen Joannes Baptista Planck, Gautruche, 1752, part 2, table 2 of illustrations, pictures 59-60 at the end of the book).

Ljubljana Franciscans also read the work of Trnava Jesuits on Mathematical sciences, describing Heron's fountain, elasticity of gases and Magdeburg hemispheres with a radius of 100 lines and a volume of 7850 of today unknown units. The book has not been signed. Its writers were Ján Ivanchich and Antal Reviczký. Ivanchich and

Reviczký published about the use of mathematics in the spirit of Theresian Reforms.

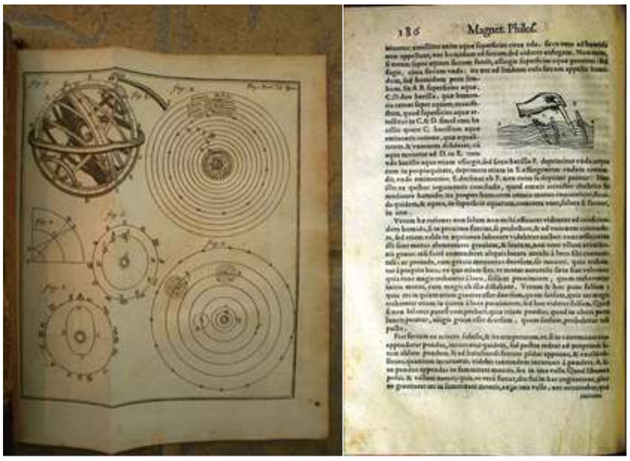

Figure 6-152: Copernican system by Jaszlinszki's Special Physics in Ljubljana Franciscans' library (Jaszlinszky, 1756, table of pictures at the end of the book)

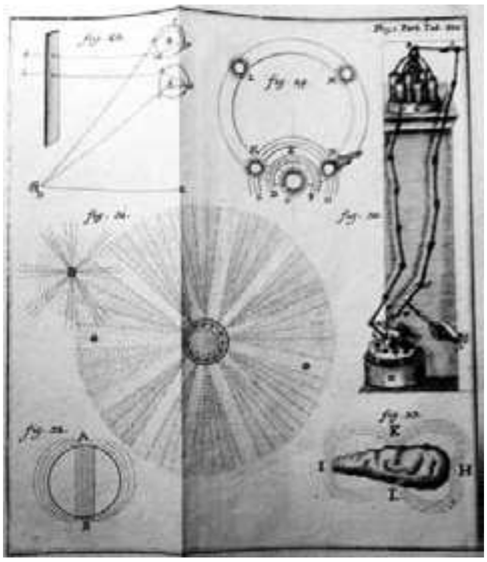

Figure 6-153: Jaszlinszky's experiments with electrostatics in Ljubljana Franciscan library (Jaszlinszky, 1756, table of images 5); F.

Ivanchich and Reviczký had listed devices suitable for determining the characteristics of the air, including Boyle's pump called *Antlia pneumatica*. Torricelli's barometer was drawn on the nineteenth figure, at the eighth picture Ivanchich and Reviczký introduced a siphon laid over the hill. On the thirteenth picture there was a hydraulic pump. The reader was advised to consult mainly the *Technica Curiosa*, *Magia Piriotechnica* and the acoustics of the Jesuit Gaspar Schott, who first described the Guericke's vacuum experiment. He seemed interesting in de Chales's *Hydrostatica*, Lana's invention of the vacuum balloon and a description of the echo in *Misurgia* of Schott's teacher Athanasius Kircher.[935]

In their conclusion, the Trnava Jesuits with Ivanchich and Reviczký onboard afforded eight tables full of pictures. At last figure they supported their chapter on Hydrometric and Aerometry with figure number 20 resembling Boyle's pump, and with the Figure 16 they added the weighted vacuumed hemispheres.

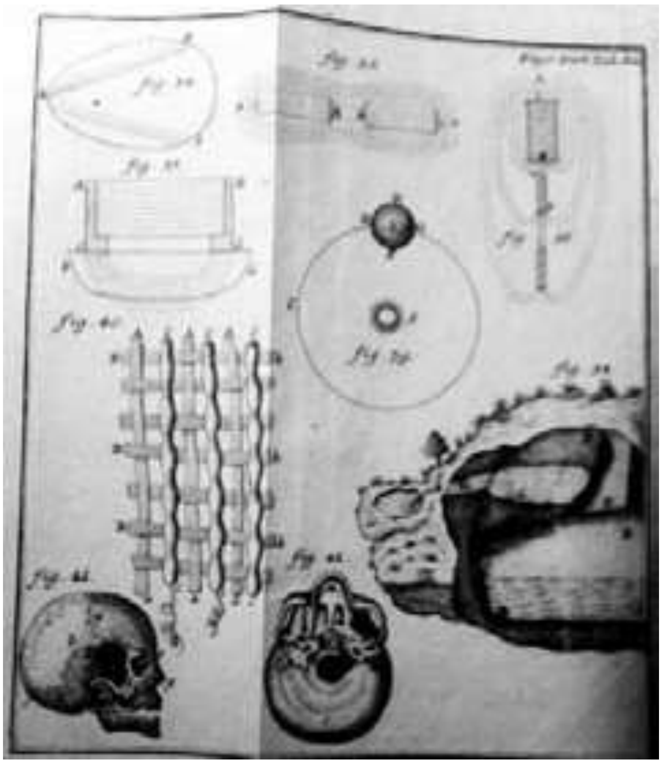

Figure 6-154: Jaszlinszky's experiments with magnetic fields of forces (Jaszlinszky, 1756, table of images 6); F.

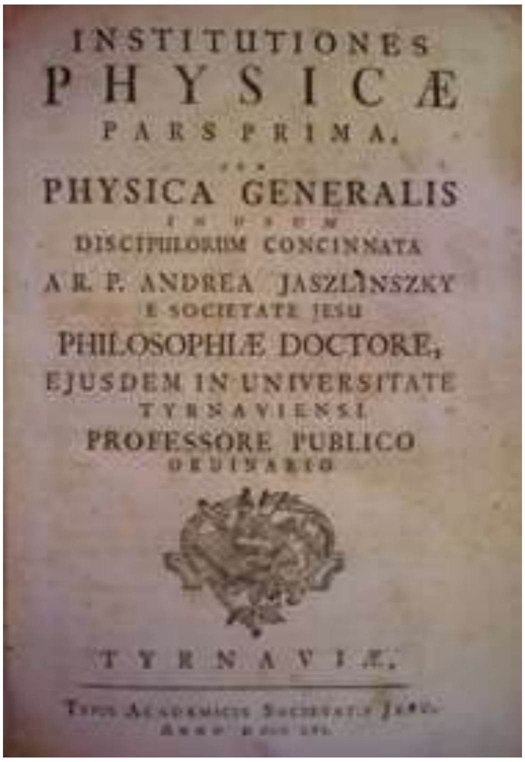
Ivanchich and Reviczký were soon supplemented by their associate András Jaszlinszky. Later in the year 1771 Jaszlinszky became a rector of Trnava University. Today's Ljubljana book of professor of physics András Jaszlinszky (* 1715 Szina; SJ D. 1783 Rozsnyó) was the property of Franciscans from Kostanjevica above Gorizia a century and a half ago in 1862. According to proprietary records, it appears that the work was exchanged by students in their late teenage years. The student Francis Xaver Joseph Winperger in 1759, the student of poetics in Ljubljana in 1801 Jožef Skaria (Scaria, Škarja) from Vipava in 1805, and the student of

[935] Ivanchich, Reviczký (The Jesuits of Trnava), 1752, 223, 230, 235-239, 244.

second class of humanities in Ljubljana in 1807 Anton Kerschel (Kršl) in 1810 used the book one after another during their higher studies. Kerschel attended his lectures of physics in the era of Illyrian provinces to become a surgeon and pioneer of vaccinations in Ljubljana and Gorizia.

In the edition of 1761, Jaszlinszky published 800 pages of physics with 16 tables. He noted Gassendi, Boerhaave, Boyle, Malpighi, Linnaeus, Harvey, Loewenhoek, Voltaire, Descartes and Francesco Redi (d. 1698) who wrote at last four times to his antagonist, one of the first vacuum researchers Athanasius Kircher.[936]



INSTITUTIONES PHYSICÆ PARS PRIMA, PHYSICA GENERALIS DISCIPULORUM CONCINNATA A R. P. ANDREA JASZLINSZKY E SOCIETATE JESU PHILOSOPHIÆ DOCTORE, EJUSDEM IN UNIVERSITATE TYRNAVIENSI PROFESSORE PUBLICO ORDINARIO

TYRNAVIÆ.

Figure 6-155: The title page of Jaszlinszky's textbook of general (theoretical) physics in Trnava (Jaszlinszky, 1756).

In the chapter on Earth Jaszlinszky was interested in electric phenomena after exemplary experiments of the academy *Del Cimento*. A special expert in electricity experiments was the Jesuit father J. Franz in the Imperial Vienna. Jaszlinszky reported the electricity in Boyle's vacuum, tested by the physician-politician Jean Jallabert (1712 Geneve-1768 Nyon in Switzerland near French border) and Maximilian Höll (Hell) in Cluj in today's Romania. Jaszlinszky described the Icelandic crystal and drew numerous experiments with electricity, magnets, astronomy and the underground karst lakes in the hills.[937]

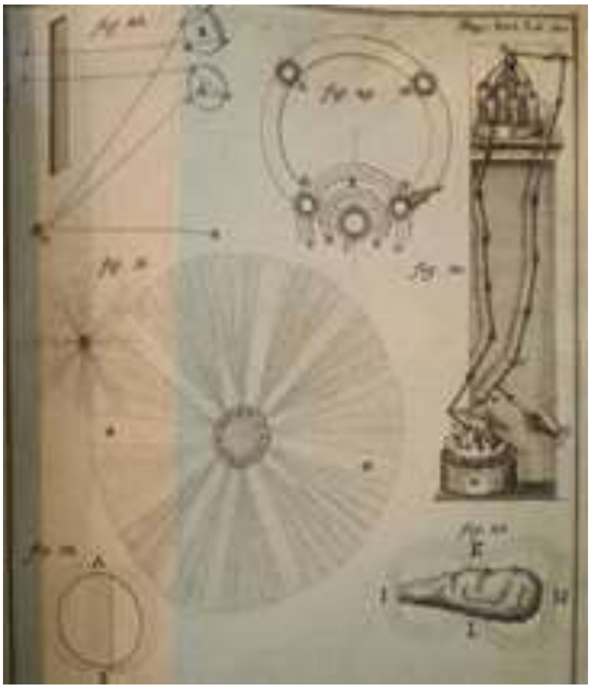


Figure 6-156: Jaszlinszky's experiments with electrostatics in Ljubljana Franciscans' library (Jaszlinszky, 1756, table 5).

[937] Jaszlinszky, 1756, 175, 176, 177, 180, 184, 189, 191, table 6 figure 38.

Jaszlinszky summarized magnetic phenomena in the chapter on fossils. He drew some good drawings of magnets, mainly magnetic rock with field lines and three other magnets with illustrated field lines.[938] He described electricity immediately after optics, while he discussed his magnetism besides the treatment of fossils and solids. Such fundamental diversity separated research of electricity and magnetism of those days, until Oersted and Faraday prepared their merger into electromagnetism almost a century later.

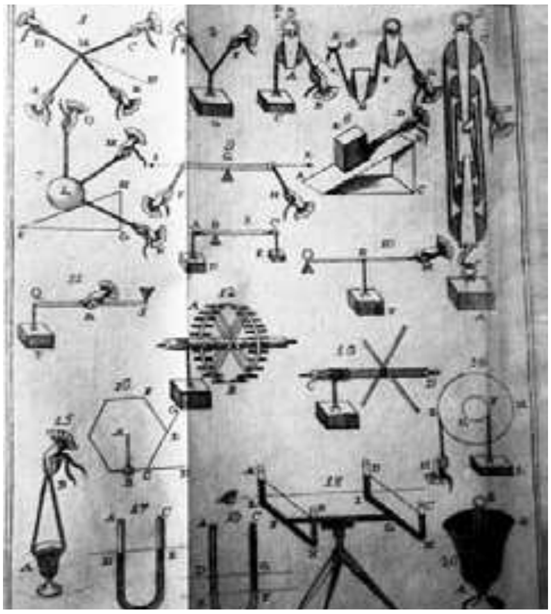

Figure 6-158: Donatus' mechanics and barometers in Ljubljana Franciscan library (Donatus Hofmann, 1754, Table of Images 1); F.

The professor of theology and philosophy as well as rector in Kempten in Swabia the Piarist Donatus Hofmann a Transfiguratione Christi Domini (Donat, b. 1703 Lübschütz in upper Silesia; d. 1783) arranged up his whole Introduction to the apparat of Philosophy in the form of questions and answers. His work was read by Ljubljana Franciscans, as well as by Škofja Loka Friars Minor Capuchin. Hofmann filled his first part of book with physics as Tomus III, while the second part was devoted to ethics as Tomus IV. Hofmann described the Horror vacui[939] which Galileo, Pascal and his brother-in-law, Francisco Perera, and Torricelli annihilated in their days. Hofmann published the sizes of Torricellian devices measured in the fingers or inches.[940] The alleged Cartesians from Minims' order theologian expert of gnomonic and perspective Plato's supporter Emmanuel Maignan (Magnan, 1601-1676 Toulouse)[941] and Cl. Pluchio (Noel Antoine Pluche) opposed the peripatetic fans regarding natural bodies.[942] The Jesuit De Lana used to be their very famous model.[943] Donatus Hofmann was a fan of the etheric substance in vacuum, although Gassendi and Newton criticized those concepts against Cartesians[944] with Newtonian attractive force.[945] The puzzle called *Rebus Aerometricus* was resolved with a barometer filled with mercury.[946] Donatus Hofmann also described the *Lacrima Batavica*,[947] hermetically sealed tubes,[948] glass tubes formed like an egg,[949] (Boyle's) Antlia as a vacuum pump,[950] vacuum-vessel with poor bunnies used for experiments,[951] and Heron's fountain.[952] Donatus Hofmann respected the opinions of great thinkers as were Copernicus, Tycho, Ptolemy[953] because he was interested in nature of light made of the substance of ether.[954] Donatus Hofmann listed Hauksbee's observations, achievements of Florentine philosophers centered in their famous Academy, (Boyle's) experiments with his *Antlia Pneumatica*, Bernoulli's observation of gravity,[955] electricity,[956] magnetism,[957] air,[958] and even the possibility of transmutation of metals[959] which looked like an alchemy of monk Hofmann's own priestly name Transfiguratione Christi Domini. Donatus Hofmann was even interested in working abilities of cannons and howitzers[960] which brought money into the pockets of those days even if it was not really in the mood of the Catholic monk.

The former Ljubljana Jesuit teacher Biwald published dozens of textbooks of Bošković's physics which the Franciscans of Ljubljana also used. Biwald described the porosity and virtual mutual penetration of bodies by Musschenbroek's experiments with vacuum pump nicknamed *Antlia Pneumatica.*[961] Biwald added a *Scholium* borrowed from Musschenbroek and by clerk Guillaume Hombergius' (William Homberg, 1652 Batavia (Jakarta)-1715 Paris) notes in *Memories de l'Academie Royale* anno 1693 page 28. In 1674 Homberg as an advocate in Magdeburg met Guericke who persuaded him to become a scientist. In 1682 Colbert invited Homberg to Paris where Homberg became a Catholic and the second pensioner-chemist of the academy in 1699. Homberg loved the alchemistic transmutations chrysopoeia (χρυσοποιία, *khrusopoiia*) while he also published a lot about vacuum in the Parisian *Recueil de l'Académie des Sciences.*

As a devoted Bošković's fan, Biwald proved the relevance of Bošković's curve with pictures as well as with words.[962] In 1788 the preacher, honorable lector, and priest Alan Makovic (Markovič, Marcobitz, Makovič, Makoviz, * 1748; OFMobs 1764; D. 26/27. 6. 1803 Novo Mesto) used Biwald's third edition of 1774. On 25. 7. 1767 in Novo mesto Makovic received his first tonsure as a Franciscan. On 23. 9. 1770 Makovic left his Ljubljana convent to become a preacher sub-deacon.[963] Alan Makovic used to be the manager of the parish Raka. Later in 1796 he unsuccessfully tried to get Kovor by Tržič parish in competition with another Franciscan, Valentin Vodnik.

Makovic subsequently wrote his marginal Latin notes with a pencil into Biwald's book of 1774. Makovic stated at the paragraph of Guericke's vacuum experiments that Guericke's pump could be used for pumping of water (implatur aqua). It's a pity that we are not sure now about the eventual Makovic's success. After Makovic's death, his bookplate in the first volume of Biwald's book was crossed out, and in the second volume Makovic's bookplate was hided with the help of red wax or adhesive. The leaves are full of sketches of people's profiles, linguistic exercises, Latin theorems and similar studies, which, however,

[963] Fr. Alanus Marcobitz, ordinis sancti Francisci minorum, ad primam tonsuram et quatuor minores ordines… F. Makoviz Alanus, ordinis minorum sancti Francisci reformatorum, conventus Labacensis dimissus, ad subdiaconatum, titulo professionis religiosae (Jure Volčjak, *Ordinacijska protokola goriške nadškofije 1750–1824*, 2nd part: 1765–1824, Ljubljana 2012, pp. 22, 120).

might not have much of a direct contact with Biwald's narrational substance.

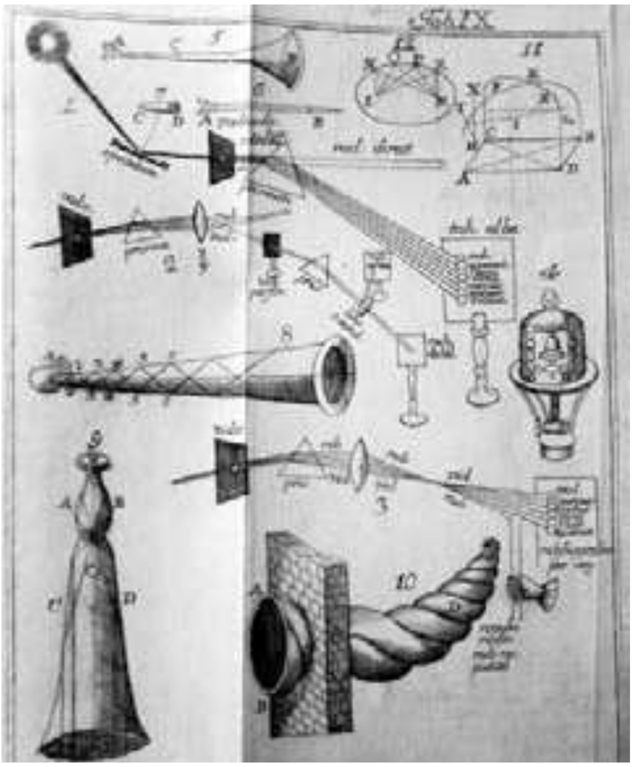

Figure 6-165: Donatus' experiments with vacuum pump and light at Ljubljana Franciscans' library (Donatus Hofmann, 1754, table of figures 9).

Benvenuto Philippitsch (Filipič) used another copy of Biwald's textbook edition of 1774. Benvenuto Philippitsch certainly was a fan of modern physics as he also used another Pal Mako's Jesuitical textbook *Compendiaria Matheseos Institutio* in Viennese edition of 1771, as well as Johan Ivančič's (Ivancisc, Ivanchich, * 1722) *Institutiones logicae* issued in Trnava in 1767, which he got from philosophy student of the first year Michaelis Hartl. On 12. 7. 1771 in Gorizia Filipič received his first tonsure and forth minor orders as a Franciscan in Sveta Gora above Gorizia. On 6. 3. 1773 he became a deacon still in Sveta Gora above Gorizia.[964] In 1776, he graduated in theology with his classmate Joanne Damasceno Herbitz (baptized Lucas, * 1754 Jesenice) in the class of Kastul Weibl (Caztallus, Castul Waibl, baptized Janez, 1741 Novo Mesto-1805). Herbitz was later a substitute priest in Mošnice. Certainly, the Franciscans could put their bookplates in the textbooks of physics or mathematics as the students of philosophy or later, as the teachers of the same stuff. Their preferred textbooks tell us much about their inclinations towards Copernicans, Cartesians, Newtonians, vacuum techniques or Bošković, but their eventual marginal notes in textbooks could be much more narrative.

Figure 6-166: Donatus' experiments using distillation at the Ljubljana Franciscans' library (Donatus Hofmann, 1754, table of figures 8).

The students used Biwald's textbooks in Ljubljana and Graz including the Škofja Loka native Martin Prenner and the Venetian count Mario Pozzo. Both printed their exam theses with famous Biwald's book *Physica Particularis* of 1769. Prenner also used the help of the Idrija mine director count Inzaghi to promote a reprint of Giacomo Bartholomeo Beccari's book. Pozzo was already a count himself, so he looked for higher patrons, in fact for the highest of them all. Pozzo devoted the

Sixteen years old Jesenice citizen Lucas Herbitz studied rhetoric in Ljubljana in 1770 while his alleged elder brother Franc Borgia Herbitz did the same two years earlier (Črnivec, 1999, 279, 282).

[964] Orožen, Ignacij, 1887. Das Bisthum und die Diözese Lavant : mit den bis zum Jahre 1854 dazu gehörig gewesenen Seelsorgestationen, als: Peilenstein, Drachenburg, St. Peter in Fautsch, St. Maria in Zagorje, St. Anna in Prevorje, St. Margarethen im Markte Montpreis, St. Maria in Dobje, Hörberg, St. Peter unter Königsberg, St. Lorenzen in der Krajina (bei Wisell), St. Nikolaus in Felddorf, Windisch-Landsber, p. 469.

second edition of the second part of Biwald's textbook *Physica Particularis* of 1769 to the empress Maria Therese together with his fifty-two exam theses of philosophy with physics, ten theses of ethics, fifteen theses of algebra, and ten theses of geometry. The noble family Pozzo had its main headquarters in Turin and 80 km southwest in the city of Biella. Soon after its printing Franc Anton von Breckerfeld (1740 Altenburg (Stari Grad) by Novo Mesto-1806 Ljubljana) acquired the book of Biwald and Pozzo in 1771. Franc Anton von Breckerfeld inherited several other mathematical books from his father Janez Žiga von Breckerfeld (1689-1760) and became Linhart's helper in collecting the historical as well as natural historical local Carniolan materials. Franc Anton von Breckerfeld's copy of Biwald's book later acquired the seal of Novo Mesto Franciscans and they passed the item to their Ljubljana religious co-brothers.

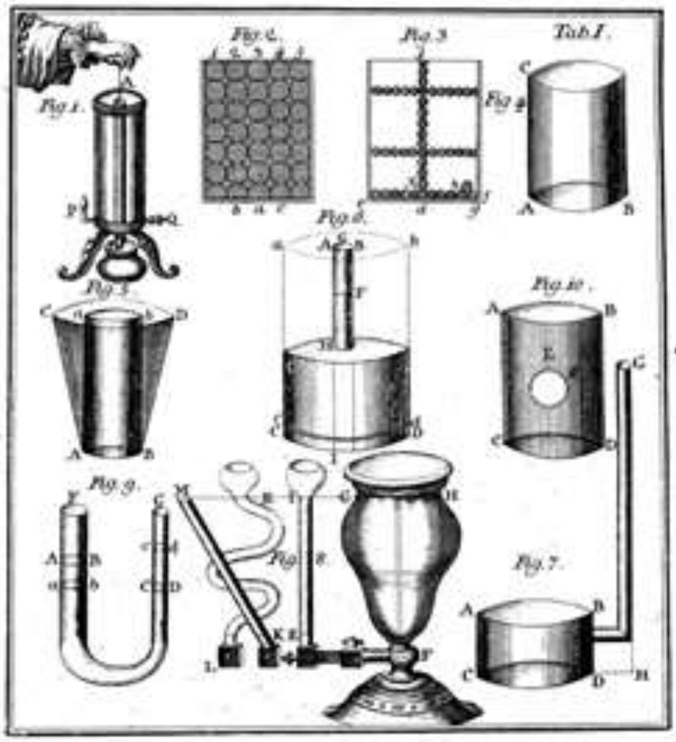

Figure 6-167: The first part of the Biwald's images of experiments with barometers in Ljubljana Franciscans' library (Biwald, 1774, first table of images at the end of the first book).

Johann Gabriel Doppelmayr's pupil Georg Friederich Brander (b. 1713 Regensburg; d. 1783 Augsburg) founded his own shop of scientific facilities in Augsburg in 1737. The Ljubljana Franciscans also had Doppelmayr's translation of Bion's book printed in the year 1712. The Jesuits of Ljubljana acquired many Doppelmayr's scientific a stronomical instruments in 1755. From 1765 to 1776 Brander has corresponded on research aids with Johann Heinrich Lambert. In 1774, Brander published twenty sketches of vacuum devices which were among the most useful in the collection of Ljubljana Franciscans. He relied on Pieter's father Johann van Musschenbroek's successes.[965] Brander was not just selling pumps, but he also offered to his buyers the appealing experiments with vacuum. He was interested in the operation of the magnet in the vacuum.[966]

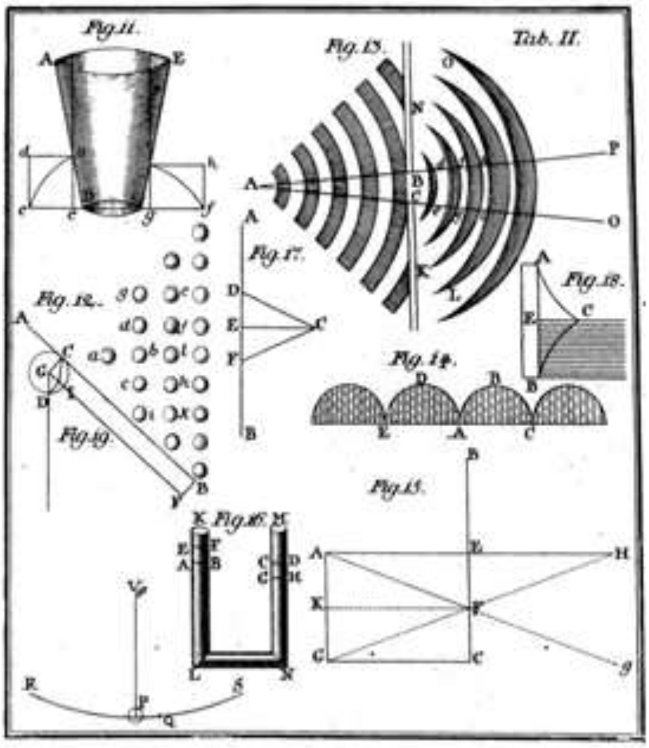

Figure 6-168: The second part of Biwald's images of experiments with barometers in Ljubljana Franciscans' library (Biwald, 1774, second table of paintings at the end of the first book).

In the early 19th century, the Ljubljana Franciscans in Vienna purchased several modern manuals for the handling of vacuum technique and maybe even the vacuum pumps for their students. After visiting France and Petersburg in 1769, Johann Jakob Ebert became a professor of mathematics at the Protestant Wittenberg University. Despite his Protestant pedigree, his books were a great match for of Ljubljana Franciscans' contemporary learning.

6.5.5 *Users of the Franciscan Books about Vacuum in Ljubljana*

The Bavarian Zinsmeister taught Ljubljana folks and Novo Mesto students all about vacuum experiments. How did Ljubljana Franciscans take advantage of the rich Bavarian books on vacuum technic in their library? What did they learn from them?

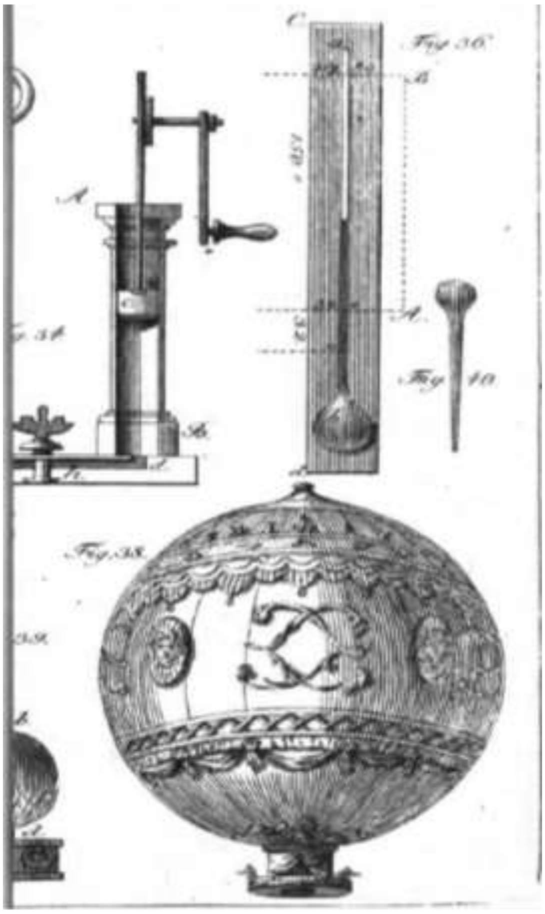

Figure 6-178: Vacuum pump and a balloon in contemporary presentation at Ljubljana Franciscans' library (Ebert, Naturlehre für die Jugend: zur Beforderung des Beobachtungs-und Forschungsgeistes in den Geschäften des bürgerlichen Lebens, Wien: Michael Schwarz, 1804, table 4).

The Franciscan magister Nicolo d'Orbellis (Dorbellus, d'Orbelles, OFMconv; † Around 1475 Rome) was among the first French friars minor Franciscan Conventual after the Conventuals were formally divided from those who were zealous for the strict observance of the rule as Observants; this division in the order was formally sanctioned by the Council of Constance in 1415 after their disputes were already cleared in 1407. Nicolo d'Orbellis studied in Paris, Poitiers, and Angers. He interpreted Duns Scotus and Bonaventura.[967] Prior to the year 1465–the Franciscan magister Nicolo d'Orbellis wrote his comments after he practiced as a professor of philosophy and theology at Angers University. Most of his works were published posthumous. His mathematics was first published in 1485 in Bologna while his physics was first issued in Basel in the year 1494.

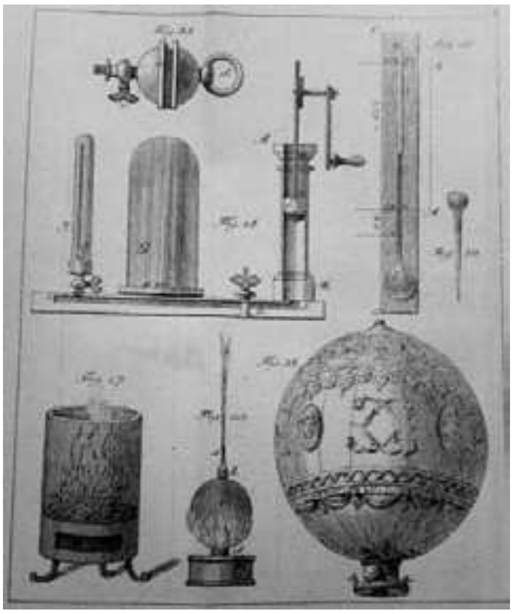

Figure 6-179: Vacuum pump and Magdeburg hemispheres in modern design of vacuum techniques at the Ljubljana Franciscans' library (Ebert, 1804, extended table 4 of a picture above).

The anthology of his books of Logic, Mathematics and Physics were reprinted in Basel in 1503, and at the latest in 1707 they became the property of Novo Mesto Franciscan Paul Novak. Novak was perhaps identical to the preacher Paschal Novak (OFM; d. 18. 2. 1764 Karlovac) or to Bonaventura Novak OFM.

The baccalaureate of philosophy holder Marko Stanzhero (Štancer, Stanzer) donated the book to Novak in the same year 1707. Marko was not of noble rank in Carniola. He was probably one of the first Baccalaureates on the just established philosophical studies of the Jesuits of Ljubljana, or he studied at the Franciscan philosophical studies as their future priest. Under Novak's signature below the title, just the part of an older proprietary entry is left. One of the older bookplates was halved during the repeated renown binding in the

[967] Donnini, 2004, 151.

right top corner of the first page. Below it is the entry of the Ljubljana Franciscans of the year 17?? with cutoff last two digits. It was certainly inscribed before Škerpin's bookplates of the year 1744, which was recorded on the internal cover. Thus, the book became the property of Ljubljana Franciscans at the latest between 1707-1744. That is the only Orbellis' book in Slovenia which has ever been found. Its printing in Basel was accomplished by Jacobus Wolff de Pforzheim while Michael Furter probably printed the natural philosophy part and perhaps also mathematical part of the volume.

Figure 6-180: Title page of starting address of Orbellis' book with notes of Ljubljana reader of 16th century, supplemented by the reader in the year 1707, namely Paul Novak from Novo Mesto (Orbellis, 1503 Summule Philosophie rationalis... incipit Mathematica, 1r).

Orbellis has published basic ideas about the vacuum, which influenced the networks of early Ljubljana Franciscans. He divided his unpaginated work into a short logic with an introduction to mathematics and geometry. He followed with a longer natural history with physics summarized by Aristotelian books. There were also discussions about the soul, ethics and metaphysics, as was the habit in those days. The vacuum after Anaxagoras as an opponent Aristotle and Scotus was the cornerstone at Orbellis' interpretation of the possible movement in the empty summarized after the fourth Book of Aristotle's Physics.[968]

[968] Orbellis, 1503 Cursus librorum Philosophiae Naturalis, 24v.

The first Ljubljana owner of the Orbellis's book from the early 16th century was allegedly the padre Thomas of Salzburg (d. 2. 4. 1541 Ljubljana), a celebrity preacher, former definitor of the province, curator, provincial minister. Because he firmly defended the Catholic faith against Lutherans and Anabaptists and many of them guided back to the bosom of the Catholic Church, his desperate opponents had twice mortally wounded him, and he finally died poisoned. The other possible owners of Orbellis's book were several times Guardian (Custos) and vicar father Angelus de Salisburgo (Salzburg, d. 9. 2. 1530 Ljubljana), the Padre Franciscus de Castelluzi (d. 26. 4. 1599 Ljubljana), the former Guardian (Custos), father Francis (d. 26. 8. 1531 Ljubljana) from the Novo Mesto, former Guardian (Custos), Padre Mihael de Achau (d. 9. 12. 1529 Ljubljana), actual vicar, former Guardian (Custos), Padre Ludwig of Slavonia (d. 11. 12. 1510 Ljubljana), a fiery preacher reverend father Jernej of Novo Mesto (d. 6. 2. 1545 Ljubljana), father Erasmus of Siebenburgen (Transylvania, d. 21. 2. 1506 Ljubljana), Padre Janez Posch (d. 3. 1. 1549 Ljubljana), former Guardian (Custos) of Ljubljana monastery father Valerian Rust (d. 17. 1. 1531 Ljubljana), former Guardian (Custos) Friar Bernardin von Ellersperg (d. 2. 7. 1505 Ljubljana), Padre Jakob of Straubing of lower Bavaria (D. 1. 6. 1513 Ljubljana), or the preacher, lector, the actual vicar, the man of deep learning and maximum modesty padre Gašper of Novo Mesto (d. 10. 6. 1509 Ljubljana).

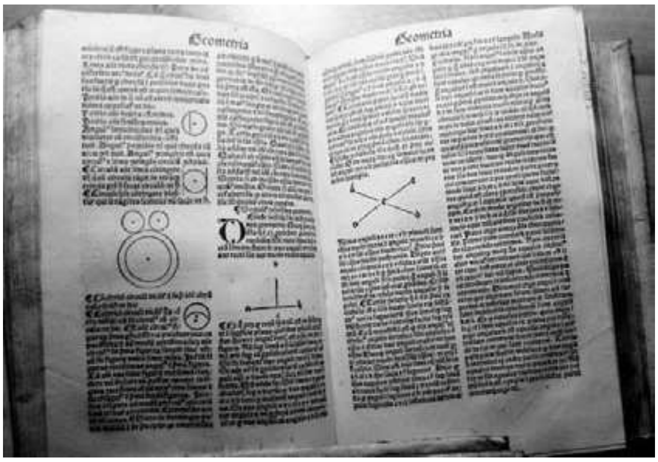

Figure 6-181: Geometric sketches on the penultimate pages of a chapter about geometry of Ljubljana Franciscan copy of the Orbellis' book (Orbellis, 1503 Summule Philosophie rationalis ... incipit Mathematica, penultimate pages of a chapter about geometry).

In the year 1491 when the Observants came in the Ljubljana Monastery, the actual Guardian (Custos) father Joahim de Freunstein (d. 10. 5. 1510 Ljubljana) became their first Guardian (Custos). Other possible writers of marginalia in the Orbellis's book were additionally the learned pater Father Bernard a Ratisbona (Regensburg, d. 1. 11. 1514 Ljubljana), or the glorious father Wolfgang of Gorizia (d. 21. 9. 1548 Ljubljana) who was a reverend old man.

In Orbellius's book, the reader wrote the headings of subchapters, and above all the clever notes in the Gothic script of early 16th century. With a little imagination, we could proclaim that marginalia design for the first bigger text on a vacuum written in Ljubljana. The clever alleged Ljubljana reader and the writer of the notes! Most of the Latin writing was devoted to Orbellis' commentary of the books of physics and, in a particular, the fourth among them, with the second chapter which was the penultimate chapter dedicated to the vacuum. So, we can have him for the first Ljubljana writer about vacuum, even if he (or even she) hasn't signed his comments after the then habit, so that we could hardly guess the writers' name. He wrote longer thoughts over the first cover and then above the cover of comments on the Aristotelian physical books. Shorter records were mostly headlined along headings of the chapters, which specifically mostly attracted the reader's attention.

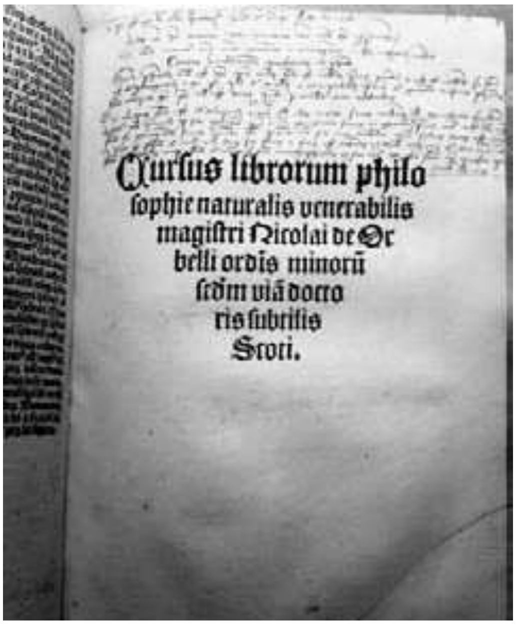

Figure 6-182: The long note of the Ljubljana reader above the Orbellis' title of the physical part of the book (Orbellis, 1503 Cursus librorum Philosophiae Naturalis, 1r).

Having underlined the chapter about the space just before the vacuum subsection of the fourth book, the reader wrote a longer note with two different inks.[969] The first note dedicated to the vacuum has highlighted the title of the Orbellis' interpretation of pressure of air: *Inflatus Plenus Aere*.[970] The next longer note refers to the Orbellis's finding that the air takes more space than water.[971] Then the reader used Orbellis' assumption that the movement in the vacuum would perform instantly, without delay.[972] The space is different from the position, and the vacuum is a space without bodies (*vacuum esse spacium privatum corpe*), which was particularly highlighted by the reader in his or her own note: *Locua Locato Differet*.[973] From Orbellis' explanation, the reader specially separated the keyword about the double-refractions (*Dupliriter repugnant*) and later with a special cursor in the form of a fist and indicator outlined Orbellis' proofs of extremely small pores in the bodies, which, however, do not allow two bodies to occupy the same space,[974] just like in Pauli's four hundred years later principle.

The reader provided the longest note of the Orbellis' claim on the dimension and position which are defining the body type (una dimensione est simuli-uno loco). The reader commented and briefly reminded: /… Amata proxima Mobilis ... in Vacuo ego Stigmit /... Vacuo aria...[975]

The Ljubljana reader briefly commented on the Orbellis' instrument described as the natural shining reflections in air (Naturalia in aere Repercusso).[976] In the fifth chapter, Orbellis was thinking about the consequences of the divisibleness (consecutio est aute), and the apparently angry reader commented on the side

margin.[977] In the middle of the same chapter, Orbellis dealt with the indivisible and the types of quantities, and the reader supported him by comments inside his (or her) marginalia.[978] The pointer with a fist was redrawn for Orbellis's interpretation of the time elapsed between motions[979] and even on Orbellis's explanations of arguments that are not false at first glance.[980] The Ljubljana reader wrote a note + accompanied with a *Number* in Orbellis' writings about the measurement of movement in the chapter about time.[981]

Figure 6-183: The first page of natural History with physics with Marginals (Orbellis, 1503 Cursus librorum Philosophiae naturalis).

Unfortunately, part of Ljubljana native marginal manuscript thoughts on the side of the Orbellis' printed book was cut off when Škerpin ordered the book to be rebound in 1744.[982] Allegedly the same Ljubljana Franciscan reader wrote with his (or her) manuscript usual for 16th century while using the browner ink; on the second occasion he or she used darker inks on the last page where he (she) wrote a table of contents with specially outlined chapters on the vacuum at the bottom of the left column at the comments on Aristotle's fourth Book of Physics.

Žiga Škerpin has greatly multiplied the Franciscan library treasures in Ljubljana. While he was in Trsat above the now Croatian Rijeka he has drawn a manuscript textbook of Aristotle's Physics with descriptions of the vacuum, which is now held in Ljubljana Franciscans' library.

The students liked to use their professors' manuscripts in preparation for the exam in those old times. Of course, in the 18th century, the professors have not yet mailed their lectures or ideas as attachments to electronic messages to their students as they have not yet filled their young heads with the World Wide Web. Not even enough good copier machines were available. Hardly likely, but it is true: they liked to use those Professor's manuscripts as the only item available.

In 1734-1736 Pfeiffer's associate Vigilij Dinarić lectured on philosophy on the Holy Mountain (Sveta Gora) above Gorizia. In 1739 he was a Lector of theology and casuistic at Trsat, during the years 1740-1742 he was a Lector of theology in Trsat, in the 1743 he Lectured on canon law in Trsat. In 1744 he was a magister on the Holy Mountain (Sveta Gora) above Gorizia and in the 1745 he was a lector of canon law in Trsat. As he was a general lecturer, the Senj Bishop took him for the Visitor of parishes of his diocese.[983] On 27. 3. 1735,[984] 20. 6. 1735[985] and 16. 7. 1735[986] in the Franciscan Monastery on the Holy Mountain (Sveta Gora) above Gorizia Dinarić finished his hefty unpaginated manuscript on Aristotelian physicists and related disciplines. He focused his 7th Question of 4th Aristotle's Book on Vacuum[987] by quoting his religious co-brothers.[988] He was interested in the resistance of the bodies, impenetrability[989] and fear of the empty.[990] In 8th question Dinarić tried to save the puzzle, the eternal controversial problem: is the absolute power of God sufficient to form a vacuum? With the quotations of Franciscan Doctor Scotus, Dinarić described water, air and fire even by Cartesian ideas.[991] In his 9th question Dinarić was looking for options for movement in the vacuum depending on (nonexistent) resistance, local movement[992] and the gravity-weight of movable dense particles of fire.[993] Dinarić described the speed of the local movement in the vacuum by St. Thomas and Scotus. Dinarić's velocity was a function of dilution, inertia, motion in resistive environment, and limited medium.[994] If the movement in a vacuum is performed sequentially (Successive), then its speed is increasing, like the movement in the water. Dinarić liked the use of a vacuum in medicine but did not describe and draw barometers or pumps. According to Aristotelian Physical books, Dinarić wrote about the Generation and Corruption,[995] about the heavens and the world,[996] about Meteors[997] and about the soul. Dinarić marked the individual planets with their ancient astrological signs along the edge of the sheet. He cited mostly the work of Ptolemy.[998] As regards the movement in our solar system, Dinarić liked to refer to the Gospels and Book of Job.[999] Dinarić did not name Copernicus or Galileo, as their works were still on the dangerous papal index.

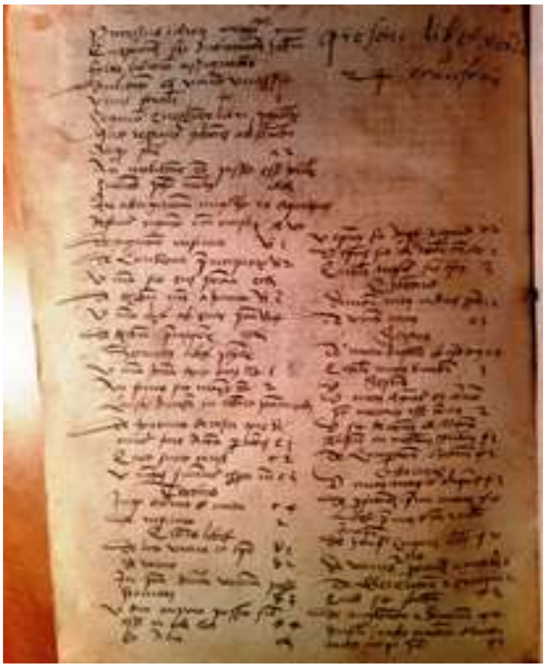

Figure 6-186: Index of Orbellis' book formed under goose pen of Ljubljana reader with chapters on the vacuum at the bottom of the left column (Orbellis, 1503 Cursus Librorum Philosophiae Naturalis, last page).

Few months after Dinarić, on 9. 11. 1735 also on the Holy Mountain (Sveta Gora) the Lector of Ljubljana Franciscan philosophy, Pfeiffer, finished the second part of his philosophical manuscript. He discussed the fourth and fifth Aristotelian book of general Physics. Pfeiffer retained the classic Aristotle's sequence of interpretations in which the description of the vacuum was the basis of the second part of the fourth Aristotle's book on Space and vacuum. So, Pfeiffer, at his seventh question, wondered whether the vacuum opposed the (conception) of the space. Pfeiffer did the same thing in his seventh question as did his fellow Dinarić.[1000] Pfeiffer was discussing the possibilities of sharing the same place by several bodies in the same room and about the possibilities for the creation of a vacuum-based experiment with an clepsydra (water clock).[1001] He relied on philosophy with physics of the Dominican professor of theology in Bordeaux Jacques-Casimir Guérinois.[1002]

Figure 6-187: Title page of Škerpin's notes to the first Aristotle Book of Physics (Škerpin, 1714, 1).

Figure 6-188: Seventh page of Škerpin's notes to the first Aristotle's Book of Physics (Škerpin, 1714, 1).

Guérinois was among the sharpest antagonists of Cartesians whom he treated with the excommunications. The Franciscans did not always love Dominicans (*Praedicatorum*), but the Ljubljana Franciscans used Guérinois book reprinted posthumously in 1729.[1003] That could prove a strong Anti-Cartesian stance among the Franciscans of those times. Guérinois's work had been acquired by Pfeiffer's eighteen-year-older master Škerpin soon after the printout. The pedantic Škerpin put his bookplate-label on it. The Ljubljana Franciscans had several other older Dominican works, including logic (1609) of the Italian Chrysostom Javellus (1472-1538), Polemical Metaphysics (1649) of Joan Martinez del Prado[1004] and Arnu's hefty philosophy. Pfeiffer has completely followed Guérinois's idea also about the possibility of God's creation of the vacuum and for local movement in it, while Dinarić limited himself to the references of the Franciscan summaries of Scotus' doctrine.[1005] Guérinois looked more deeply into Gassendi's atomism and experiments with (Boyle's)

pneumatic vacuum pump[1006] in his second and third volumes concentrated on physics.

In the next paragraph, Pfeiffer tried to explain vacuum with the ideas of Scotus. After the description of liquefaction, Pfeiffer's attributed the creation of the miraculous vacuum to God.[1007] He cited Descartes[1008] in the same explanation with Pfeiffer’s religious co-brother Scotus[1009] and Aristotle.[1010] Pfeiffer described the absolute power of God in his divine creation of the vacuum in the first query of his article number two, Dinarić was doing the same thing in his eighth query. They both rejected the misguided Descartes’ description of Vacuum.[1011] Dinarić and Pfeiffer wrote much like the Croatian-Littoral captain in Bakar and Rijeka between 1716-1735 Adelmo Antonio count Petazzi of Novigrad in the responses to Descartes for the sake of God's creation of an otherwise infeasible philosophical vacuum.[1012] Adelmo Antonio count Petazzi’s son Leopold Hanibal Josef Petazzi (1703-1772) became the bishop of Ljubljana in 1760, which helped the popularity of Adelmo Antonio count Petazzi’s books that Dinarić and Pfeiffer read in the Ljubljana Franciscan Library.

Figure 6-189 : Petazi’s Sketch of the Movement (Petazi, 1723, 280).

In the following, Pfeiffer was more dedicated to exploring the movement in the vacuum in three questions, while Dinarić resolved puzzle of the empty just with one very short question.[1013] It seems that experimentation was not Pfeiffer’s or Dinarić’s better side.

Figure 6-190: Pfeiffer’s title page of the year 1735 (FSNM).

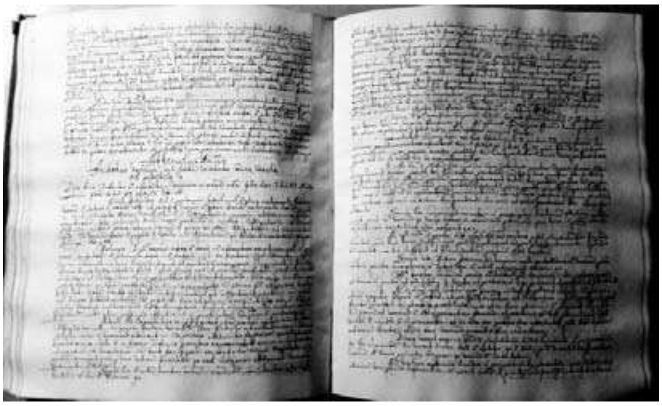

Figure 6-191: Pfeiffer on vacuum (Pfeiffer, 1735, 22-11v).

The upper Carniola (Gorenjska) Scholastic Scotus’s follower Gotfrid Pfeiffer of Novo Mesto has taught the younger Franciscans for many years in Novo Mesto and Gorizia. He loved astronomy, but for the sake of Papal ban he could not be too enthusiastic about Copernican novelties. As a Franciscan theologian and representative of the Scholastic philosophy, he was of course a fan of Scotus’ interpretation of the Aristotelian natural

history works. In 1735/36, the Jesuits placed Pfeiffer as a professor of physics at their advanced semi-university studies in Gorizia. Pfeiffer wrote six Latin texts, half of which are kept FSNM.[1014] For his Gorizia philosophical lectures he wrote down his works on the Sveta Gora (Holy Mountain) monastery, which was one of the headquarters of Scotus' fans from the 17th century onwards. Pfeiffer wrote philosophical work *Cursus Philosophicus Praelectus iuxta mentem Doctoris Subtilis studiosae Juventuti* from which only the second part of his manuscript was preserved under the heading *Complectens Scientiam Natural, seu Physicam universam*. It focused on the philosophy of nature and general physics.[1015] After his physics, Pfeiffer put his file *About the world, the sky and the elements* (*Incipiunt libri de mundo, coelo et elements*)[1016] on 1. 10. 1736. Pfeiffer described the structure and properties of the universe in the Leibniz' sense and mused-speculated on eternity and supposedly the best of all worlds (*Meliorem et perfection*).[1017] In chapter *About Heaven and celestial phenomena* Pfeiffer was discussing the number of heavens (*Orbs*) around the stars, the Milky Way, the sunspots and lunar "spots".[1018] While questioning the movement of the sky Pfeiffer argued against Copernicus' bronze plate of the sun. Pfeiffer discussed Kepler's ellipses where the smaller earth circulated the bigger Sun like the chickens circulated their hen.[1019] Pfeiffer described Galileo's observation of the reflection of light on concave mirrors or the celestial machine as the opposition to older writers.[1020] Galileo deprived the moon of the light of its own. Galileo erroneously denied the role of the moon in tiding which Pfeiffer did not note. Pfeiffer discussed meteors which he rightfully put on the areas above moon[1021] and explained several other astronomical features.[1022]

Pfeiffer performed the highest functions in Franciscan order. In 1745 he was even Guardian (Custos) in Novo Mesto, and the next year he became the first Novo Mesto High school headmaster. He became the provincial of Croatian-Carniolan Franciscan Province (1748-1751) as a Ž. Škerpin's successor. On that highest position Pfeiffer was re-elected between 1757-1760 and 1766-1769.[1023]

A decade after Dinarić and Pfeiffer, the other Ljubljana Franciscan lector had left his manuscript of physics unsigned in 1744/45. On 27. 8. 1745 on the session of their definitorium leaders the

Franciscans selected the lecturers for their new jobs; then they arranged also the lecturers of philosophy with physics. So, they had the lecturer of Philosophy Paulian Korač in Sveta Gora for the year 1744. In Novo mesto Hieronim Markilič and Bonaventura Vietrih lectured. In next year 1745/46 on the Holy Mountain (Sveta Gora) Korač and Hugo Vodnik lectured. In Novo mesto Krizostom Perkopac and Šuštaršič taught, at Klanjac in Croatia Bonavio Dietrih and Hieronim Markilič lectured. On the General Studies in Ljubljana lectured Vincent Marjašič and Ambrož Bedenčič (OFM died on 4. 4. 1750 in Kostanjevica) who served as a general Lector and vicar in Jaska, and at Trsat.[1024] Zaharia Matko taught at Trsat and the magister Avrelij Zevko (Čeuko, Zheuko, Frans Aurelium Zhenkho, D. 1746 in Ljubljana) taught the Franciscan youth in general studies of Ljubljana.

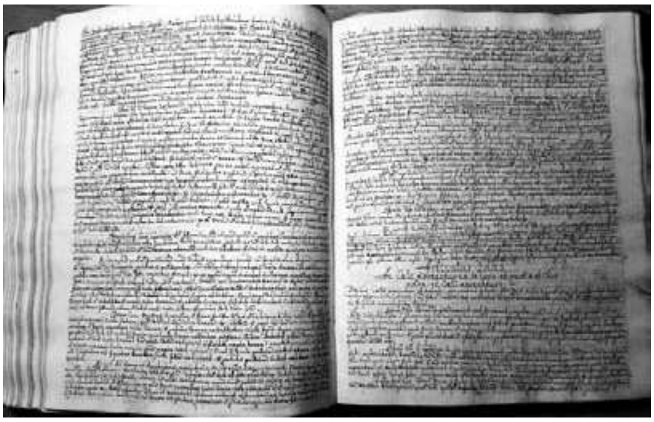

Figure 6-192: Pfeiffer's opinion on the Copernicans and Galileo's work which was put on the Papal Index of prohibited Books (Pfeiffer, 1736, 31-11r, paragraphs 2 and 3; Benedict XIV, 1758, 118).

The comparison with manuscripts from the era 1769-1774 shows that Markilič did not produce the work of 1744/45. The similar comparations with Zevko's bookplate in Duhan's book in FSLJ shows just some similarities in writing the letter A, and much less in writing the letter P. Zevko used Duhan's book of FSLJ while he taught philosophy in Ljubljana Franciscan studies in 1727. The most likely authors of the manuscript of 1744/45 were Vincent Marjašič or Ambrož Bedenčič. Marjašič used many books from Ljubljana Franciscan library, but he put his printed bookplate in them like Škerpin, therefore Marjašič's handwriting is not recognizable and provable as far.

Figure 6-193: The title page of the physics of Ljubljana Franciscan professor who taught in the year 1745.

The author of manuscript of 1744/45 paginated only the couple of his initial sheets and the beginnings of his paragraphs. He provided no index. At the end he specified the date on 3. 9. 1745. In between, the older dates of the same year figured at the ends of individual books. He dedicated a brief introduction written on less than one page focused on the working with scientific devices. Firstly, of course, he wrote about the ancient origin of the term physics,[1025] as usual in those times. He followed the Aristotelian books including his third book of Physics.[1026] The 4th Book of Physics was the most interesting vacuum piece,[1027] as usual in Aristotelian frames. *Disputatio Secunda* Or *Quaestio Secunda De Vacuo* lacked the pagination except on the beginning of paragraph.[1028] The third question asked about the vacuum and movement in it. Can

the bodies move in a vacuum?[1029] The vacuum section ended 4th book.

The fifth book was dedicated to the infinity.[1030] Of course, the author relied on Scotus.[1031] On the side he put marginal corresponded additions and insertions marked with plus signs.[1032] He had the infinity for the category of God.[1033] On 21. 5. 1745 the comments in Aristotelian fifth book were completed with citations and references of other writers,[1034] which could not yet include a young Bošković.

Figure 6-194: Sketches of Ljubljana Franciscan professor from the year 1745 (Anonymous, 1745, 204r).

The sixth book began by addressing the continuity[1035] and citations of the Angelic doctor Scotus. The only three recognizable sketches were afforded on the second page of the second question of the sixth Book of Physics under the title Ars Continuum ex Solis Indivisilibus Componantur? The author put them at the bottom of the page, describing Zeno's paradox in the movement of Eagle and turtle. With points, tangents and instantaneous movements he proved the paradox to be absurd.[1036] The chapter has been updated with the hefty marginals added somewhat later, not during the teachings of the same guy, but by some other later reader, who could have been the next Franciscan lecturer of philosophy.[1037]

The author then dealt with the other Aristotelian books of physics very briefly, among them with seventh book of physics.[1038] The remaining Aristotle's ideas about the natural sciences has only been summarized as a learning of *Tractatus sinopticus de omnes libros de coelo, Mundo et Metheoris*[1039] by reading some sporadic puzzles.[1040] The writer had more to say about Aristotle's book *De Anima*.[1041] He finally embarked on metaphysics.[1042] His text was further complemented by the Ljubljana Franciscan professor(s) who taught after the year 1745, as is evident from a few Marginals written after a long time on the side of the original text completed at the beginning of the school year in September 1745. Unfortunately, the writers did not add any topics index, so that remarkable peripatetic manuscript written with the letters of the condensed font is somewhat nontransparent.

In the middle of 18th century the Franciscans of Ljubljana produced another similar bulky extensive manuscript. The last pages of it are sadly missing, therefore, the name of the writer is unknown, and the year of writing could be just approximately put in 1750-s. The anonymous writer still declared that the nature is afraid of the vacuum. The writer claimed he could explain the burning of a candle in the air and in a vacuum. The Almighty God can create an impossible vacuum, which is a miracle. God's finger thus allows local movement in the empty including the local movement of omnipresent angels.[1043] He insisted on four elements: fire, air, water, and earth.[1044] He did not mention then already a century old vacuum experiments because he preferred good rhetorically sound logic and not eventually otherwise shaped reality. In the only partially preserved astronomical conclusion of his notebook, he advocated the rotation of the sky within 24 hours without specifically pointing out the opposite Copernicus's opinion.[1045] Later the author added some vertical marginal notes. He quoted just some of his models like St. Augustine, St. Thomas Aquinas, Scotus, or

Aristotle. Among his contemporaries the author moreover noted Fonseca, probably Pedro de Fonseca as one of the first followers of St. Ignatius or more likely the Franciscan bishop in Évora in Portugal José Maria Ribeiro Fonseca.[1046] Imaginary spaces have been described by the data of Bonaventura Baronius.[1047]

In the manuscript bind to Dialectics written in the same year the now anonymous Franciscan writer narrated about the general physics as a science in 1768. In dei nomine tractatus ad universam Physicam sey Scientiam Naturale the Franciscan author wrote 192 pages with their unpaginated subject matter index added at the end.[1048]

First, the writer explained some particularly puzzling effects of the sparks of fire, fluids like water or air, the extinguishing of candle in vacuum, and lighting. He described the systems of atomists like Democritus, Leucippus, Gassendi,[1049] or Descartes as the wrong systems of ideas.[1050] The chemists connected with the alchemists were nicknamed spagyrically in the habits of those days. They reasoned on the basis of individual elements used in their transformation processes.[1051] The writer later added on his marginal side the notes on the observations of "Clarissimi" English anatomist the secretary of RS Nehemiah Grew (1641-1712),[1052] and finally highlighted exploration of Grew's senior collaborator Boyle focused on salts and mercury.[1053] The writer explained the elementary systems of Empedocles from Akragas (Ἀκράγας, Agrigento) in Sicily, Pythagoras or his fans and his pupils based on atoms as the elements.[1054] The writer was interested in Achilles' puzzles and in the theory of four elements[1055] according to the bishop of Cyrus named Theodoret (c. 393 – c. 457).[1056] The writer also discussed the other philosophical systems of Anaxagoras as narrated by Aristotle. He explained ideas of Zeno and Plato, with Descartes included. Among the new scholars there was Isaac Newton with his impenetrable massive atoms of solids,[1057] Leibnitz's seemingly misguided psychology with Monades and active forces. The "Clarissimus" Christian Wolff as Leibniz' fan was noted separately with his material atoms of masses discussed inside the paragraphs about physics which was discussed apart from other paragraphs devoted to arithmetic. The writer explained Wolff and Leibnitz's ideas on the whole page, while Newton deserved only much shorter paragraph just ten lines long; that neglect of Newtonian physics was about to change in Habsburgian approach of those times after the school authorities preferred Bošković's combination of Newton and Leibnitz's approaches over the older Franciscan Duns Scotus and similar peripatetic ideas. With that in mind, the author was certainly not yet a Newtonian but a fan of the neo-Cartesian doctrine of Noël (Natalis) Regnault which gained the popularity among the Habsburg Jesuits of those times although Regnault preferred Descartes against Newton mostly as a French nationalist. The writer stated so many puzzles which were resolved by the Jesuit father Regnault in second part (Tom 2) of his Physics regarding ethers and flame according to the Egyptian and Herodotus's doctrine.[1058] Finally, the author explained the Peripatetic system on several pages without quoting any writers.[1059] Of course, the Ljubljana Franciscans observants kept Regnault's Physics at last in three Latin language editions of 1736, 1747 and 1755, all of them published by the Jesuits Josef Staininger and Dollenz in offices of the local printers the Tyrolean Joann Jacobus Jahn (Jan) in Steyr and Widmanstad in Graz. The barefoot Augustinian pater Anastasius and Ljubljana Jesuits in 1754 and Erberg got their Latin language Jesuitical Carolus Dollenz's translation of Regnault which later went to Ljubljana NUK and National Museum libraries, while the Piran scholars preferred the earlier Italian Venetian translations of 1736. Finally, the Franciscan writer has delivered the basics of the Peripatetic system without noting his sources. According to the metaphysical interpretation of

matter and form, he embarked on a system of contemporaries without quoted names[1060] and then he discussed a mechanical system[1061] among which he involved peripatetic and especially the Cartesian Nicolas Malebranche.[1062] Along with the natural positions he first briefly explained his vacuum in the Sectio 3[1063] where the author cited mostly Gassendi's assumptions.[1064] In the Sectio 7 with its paragraph 2 the Franciscan writer provided a treatment of philosophical vacuum which that author discussed more profoundly in three aspects formed as the objections against his more peripatetic old fashioned unnamed opponents:

1. Vacuum is again noted in cases of amphorae containing the detectably moving fluids, as a recurrence of motions;
2. Vacuum in space, its locations in hyperbolas, fullness of substance of vacuum;
3. The double definition of vacuums in liquid water and in gaseous air was explained while it was extended to a large scale according to Gassendi.[1065]

Descartes and a modern Newton described the philosophical vacuum. The accumulated vacuum under the principles of Newton was a void whose existence was supposedly proved according to experiments on separation or discontinuity. The Franciscan author provided his first opposition: Torricelli's experiment rises the level of mercury for 28 fingers (inches) in the tube, prevents the access of air into the tube, while vacuum is supposedly formed and maintained in intermediate space of the recipients or vacuum pump *Antlia Pneumatica*. The experiments were designed in a vacuum above mercury or in a pneumatic machine named *Antlia*. In his first objection the Franciscan author described the Torricellian experiment and the lifting of mercury for 28 fingers in the tube while vacuum maintained the intermediate volume. The rest of mercury prevents the access of air. Similarly, the recipient worked in the Pneumatical pump (*Antlia Pneumatica*). The light affects the pores of the glass, as also heat and cold could. The Franciscan author also cared about the behavior of fluids in the vacuum.

In the second objection the Franciscan author was experimenting with cold and hot water. He filled his container with oil and ignited a small flame, while the vacuum penetrated in the space previously occupied by oil.[1066] If the Franciscan author prevented the access of air to the his source of light, it turned off while the air was forced up and replaced with a vacuum. The Franciscan author worked with a hammer on a very fragile substance. The drops which were slowed down would take place during motions in the substance, so as it happened with the movement of the planets in the vacuum, which the vacuum permits without friction. The same goes for the movement of comets through the finest fluid, as well as also the motion of light of stars and the sun. The warmth of the cosmos is exceptional for the sake of subtle ether. The planets are moving and the sun shines. The vacuum builds up and accumulates because the fullness of a world would impede and hamper the motions. The rarefied vacuum again paradoxically refills the liquid space of the universe. A complete full environment would hinder movement; so, the dilemma keeps the paradoxical empty space constantly flowing. Experiments with vacuum pump have rebutted the presumption of fear of emptiness. The dilution fills (in fact, empties) the space. Experiments with (Boyle's) *Antlia* refuted the assumption of fear of vacuum. The Ljubljana writer has precisely written the size of individual parts of the pump, but failed to mention Boyle by his name, probably because the Protestant Boyle was not a best reference for the young Franciscan students. Tube put at fountain (*Syphunculus*) was 60 feet long, i.e. almost 20 m[1067] which corresponded to the pressure of the two atmospheres.

In his third objection, the Ljubljana Franciscan writer was interested in the thickness of the air layer (atmosphere). In this he outlined the prevalence of the vacuum in nature and supported the atomists in their dispute against the Peripatetics; he also praised the advocates of Ptolemy who were more favorable to vacuum. The shaking (vibrations) of atoms is disseminated by vacuum while the vacuum separates atoms from each other.[1068] The Franciscan author explored the movement of flies and the impulses by Newton's theory based on the experiments with a wooden

ball and leaden heavy hard balls. Both have the same resistance, which vanishes in the vacuum where the balls behave regardless of their density.[1069] Despite their unequal weight, it is expected by the Galileo's imagined experiments that they should have the same speed during their free fall in a vacuum. The Franciscan author was interested in penetrating of the vacuum into a fluid. Next, the Franciscan author discussed the cohesion of the solidified matter[1070] in the famous experiments allegedly involving the attraction between atom until J. Stefan proved that the other kinds of forces must be involved in that type of cohesion.

The Franciscan author then added appendix to discuss the allowing specifics of the local successive movement in the vacuum, during this successive, not completely instantaneous motion.[1071] Then the Franciscan author embarked with definitions of motion in his 4th section.

The Franciscan author was interested in flexible movements,[1072] reflection and refraction,[1073] as well as he wished to learn about the laws which governed the motions.[1074] He wrote about the fire,[1075] earth,[1076] and in his last dissertation he focused on special qualities and mostly on warmth[1077] and cold.[1078] He avoided mentioning any electricity, magnetism or optics which belonged to the other branches of particularly developed experimental physics. He wrote about fluids,[1079] specially about the motion of solids and fluids.[1080] He illustrated the movements caused by gravity with the examples used by machinery.[1081] He was interested in the pressure of fluids,[1082] the hydrostatic principles[1083] and in the last section he discussed the weight of air.[1084] His mass of air was described with the experimental designs of *Antlia Pneumatica* which the Franciscan author noted as Guericke's invention allegedly pictured on fig 1 of table 7, which were, sadly, not attached anymore in his preserved manuscript in FSLJ. He then described a whole row of range of nine experiments, including those designed to protect the plant from putrefaction. For the pneumatically designed machines the Franciscan author used the names Torelli and Jaglini; the first of those may be abbreviated for Torricelli, while the other might be a misspelled family name of Viviani, although many architects and other designers named Torelli also worked in those times. Such funny mistakes with the names cited were not unusual in manuscripts written by the lecturers who were not professional naturalists but happened to be hired as professors of physics within philosophy just for a while before they were offered the more respectful jobs of theologians or administrators. There was no per-reviewing to correct those unpublished manuscripts.

Figure 6-195: The appendix about movement in a vacuum in Ljubljana Franciscan professor from the years 1768 and 1771.[1085]

Next, nine experiments were carried out in a row, including the protection of plants against rotting. The Franciscan author explained a Torricelli's tube filled with mercury,[1086] even in suspension of vacuum in vacuum of Huygens' invention. The Franciscan author was interested in observing and

measuring the elevations of higher positions on the hills carried out by Pascal's brother-in-law at Fig. 3 Tab 7. The pipe used had a height of 32 feet.

The design of *Antlia pneumatica* was described in figure 2 of table 8 and the Franciscan author outlined the weight of the air also in his notes on the siphon at the second question on Fig. 4 tab 8. On Fig 3. tab 9 the Franciscan author described Musschenbroek's accomplishment. He knew much about the adhesion of water during the Hugenius' test, where he used the misspelled Latinized Huygens' name. The pipes could also use wine instead of mercury. There was a subtle ether in pores of glass near mercury.[1087] With a reference to Musschenbroek the Franciscan author compared the weight of air, steam and water as did other Franciscan writers of those days but that same very agile Franciscan also provided the numbers measured. In the third question of the rising of Mercury in the pipes the Franciscan author also acknowledged the changeable force of gravity while we approach the Equator.[1088] He again mentioned the suspension of Mercury,[1089] certainly the one from Idrija. He discussed the relationship between Earth and ether and the color of the air at higher altitudes. The Franciscan author was interested in measuring heat and cold. He merely listed the barometer, baroscopium, manoscopium, pressure gauge, termoscope as the discontinued variant of thermometer, hygroscope as the discontinued variant of hygrometer. Then the Franciscan author provided a broader description of the listed devices, beginning with the barometer full of mercury on Fig. 5 of Table 9.[1090] He then embarked on a baroscope to measure the changes in the weight of air, manoscope to measure air density and thermometer also stuffed with the wine according to the Musschenbroek's instructions, or in Daniel Fahrenheit's design with the (Idrija) mercury. The Franciscan author used also a Florentine thermometer and described its scale. Later, the Franciscan author added with a lighter ink notes about his ability to determine the cold. He described the Hygroscope with iron (ores) for the measures of changes of moisture of the air at figure 9 of table 9.[1091] The Franciscan author used a slightly lighter ink in his last paragraph before the prayer to St. Francis and the saints. He devoted it to the summary of all these experiments. He relied on the second section of his manuscripts for the options of the water.[1092] The Franciscan author described the machines evolving from the simplest to more complex whose peaks were his vacuum measuring devices with barometers, thermometers and pumps. He didn't mention the steam engines.

The Franciscan author's book of 1768 has a slightly larger format compared to the books of the same writer issued in the year 1770-1771. He then also used the similar binding with leather covering spines and edges of a book, but he designed a more colored marmorated cover in 1768.

During the years from 1772 to 1774, the other Franciscan wrote on general physics for the instruction of his students. He described the pores with a vacuum and wondered if the vacuum was maintained, as a self-sustaining vacuum. He opposed the then modern enthusiasm for the ideas of Gassendi with Epicurus included and described Torricelli's mercury tube. The achievements of vacuum pumps experiments were most disturbing. Among all the substance in question the author was the most affected by the achievements of vacuum pumps. Upon re-reading his own manuscript, he did not add only side notes to his own handwriting, but he had to stick an additional sheet, and he soon ran out of space for the sake of many novelties intended to inform the reader. He described the views of the Atomists like Leucippus, Democritus, Epicurus and their contemporary heirs, a subtle substance and a fluid molecule. He was especially delighted and impressed by the Antlia pneumatica vacuum pump with which Musschenbroek tested the properties of mercury, even though the Franciscan writer still conditioned the existence of a vacuum with the operational intervention of God. He explained the events in Torricelli's tube and vacuum pump with Newton's and Lucretius's atoms. He additionally described interesting experiments with water, wine or burning of a candle. Antilia pneumatics created a vacuum and that was possible despite the quotations of Book of Job from the Old Testament. Job's tirade Book of Job 3: 5: *Let it never have been created, Let it sink back into the void, Let chaos overpower it.* And again, in Book of Job 6: 18: *Going up into the void and perish.* And, finally in Book of Job 26: 7: *He stretches out the north over the void and hangs the earth on nothing… God puts solid good in the void*

where Satan dwelt. There are some voids noted even in the Genesis 1: 2: *The earth was formless and void, and darkness was over the surface of the deep, and the Spirit of God was moving over the surface of the waters: formless and void* (tohu-va-vohu). The denial of void in the Bible was far from explicit, even less convincing than the seemingly Anti-Copernican stance in Joshua 10: 13: *And the sun stood still, and the moon stopped, until the nation took vengeance on their enemies. Is this not written in the Book of Jashar (Jasher, סֵפֶר הַיָּשָׁר)? The sun stopped in the midst of heaven and did not hurry to set for about a whole day*. Therefore, it was not hard for the Franciscan writer to replace the fear of emptiness with the weight of the air. The vacuum is possibly supernatural, although it is rejected by the Cartesians; it could have been aligned and reconciled with the updated science of Franciscan Duns Scotus.[1093]

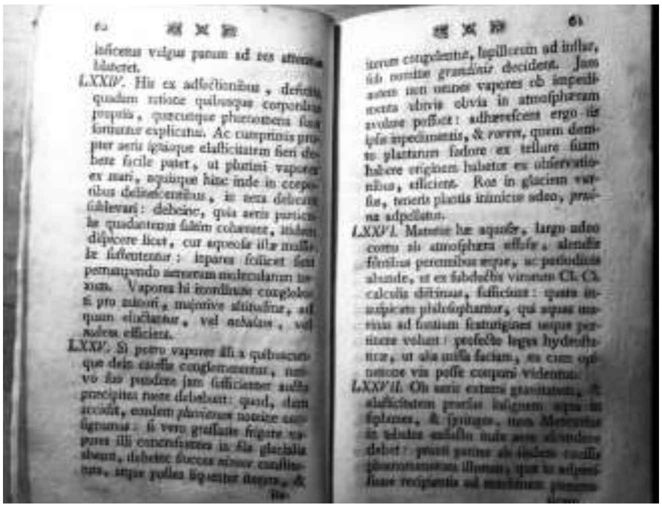

Figure 6-196: Questions about vacuum pumps at the Innsbruck exam at Kapferer’s class, stored at Ljubljana Franciscans’ library (Kapferer, 1778, 60-61, with the permission of Prof. Dr. Miran Špelič, OFM).

In 1774-1775, the same writer with the identical handwriting compiled Special Physics. He described the Copernican system, sketched Kepler's ellipses, noted Ptolemy and Tycho. He quoted Fortunatus Brixianus’ descriptions of astrology before dealing with meteorological phenomena. He maintained Beccaria's opinion of the natural light of fluids, and he was especially interested in the achievements of Musschenbroek; he used the calculations of the speed of light on its way from the sun to earth and he reported about Bourger's research. Finally, the author of 1774-1775 manuscript described electricity; like Jaslzinsky or Zinsmester, he described conductors (symper-electrics) and experiments with electric sparks without mentioning Franklin. Referring to the tourmaline, the author of 1774-1775 manuscript noted Musschenbroek; he also described the underground and magnets.[1094]

The Ljubljana Franciscan Higher education of those days have been in many ways modelled by their co-brother experts from Tyrol. The teachings of those days in Tyrol were beautifully illustrated with 75 physical exam theses about the bodies and with 54 mathematical theses. The students had to defend their abilities in the class of the Franciscan Professor Simon Lypnica Kapferer in the monastery of Hall in Tyrol east of Innsbruck. Lypnica Kapferer’s designs of vacuums in barometers and pumps were described in a modern way.[1095] They scorned alchemy a little bit and accepted Newtonian Optics.[1096]

6.5.6 Bavarian Vacuum for Ljubljana Franciscans: Bavarians Taught Vacuum Technology to Carniolan Literati

6.5.6.1 Ljubljana Franciscan Manuscripts about the Mathematical Sciences: Hieber from Cham

Zinsmeister and other Ljubljana Franciscans widely used the manuscript textbook exam theses of Zinsmeister’s older Bavarian compatriot, the lecturer of philosophy Castul Hieber (* 1761 München; OFMobs 1780; † 18. 8. 1810 Ingolstadt) from the monastery Cham (*Cambiensi*) in East Bavaria 50 km northeast of Regensburg. Hieber was probably of Slovenian origin because the nobles with his last name owned the manors in Vipava valley. The Franciscan Hieber defended his polemic and dogmatic theological PhD exam on historical aspects of sacraments and dogmas in

[1094] Anonymous, 1774-1775, 1 / 22v, 2 / 1r (November 24, 1774), 4 / 1r, 8r (in margin noted Beccaria’s publication in Acts of Bologna), 8v, 9r, 10r, 10v,14r, 16v.

[1095] Lypnica Kapferer, 1778, p. 61-62 (thesis 76).

[1096] Lypnica Kapferer, 1778, p. 58 (thesis 72), p. 64-65 (Thesis 85).

Munich in the class of Rupert Prößl (Proessl) on 4. 8. 1785 and on 20. 6. 1786. Hieber or his students accomplished two manuscripts based on Hieber's exam theses which Zinsmeister himself or one of his Bavarian colleagues brought to Ljubljana. Hieber signed one of the manuscripts on August 11, 1796 and filled its pages with discussions on philosophy, mathematics, and some contemporary Herschel's astronomy about the Uranus' and Saturnus' satellites and comets for the conclusion.

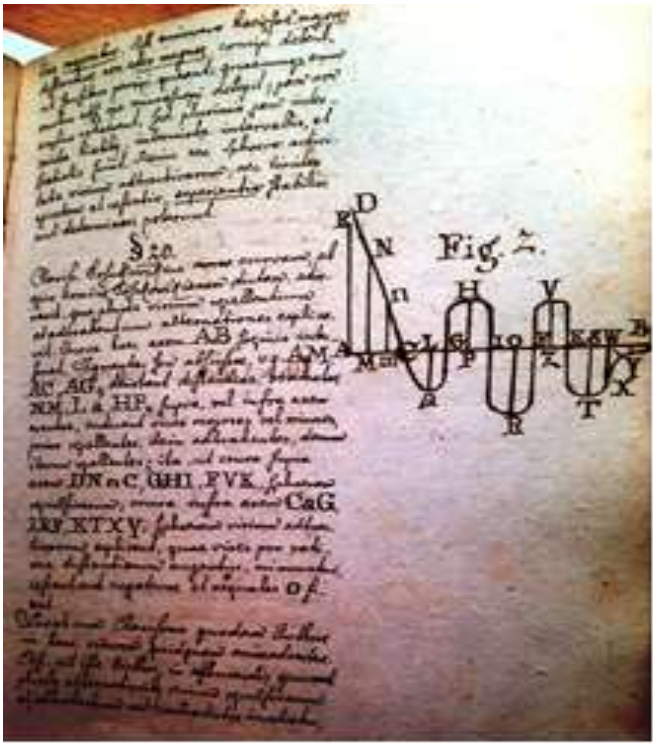

Figure 6-197: Zinsmeister's figure of the Bošković's force (Zinsmeister, ibid., 2: p. 23 (The courtesy of Dr. Prof. Miran Špelič, OFM)).

Figure 6-198: Hieber's sketch of his experiments with fluids (Hieber, ibid. 1797, p. 66 (The courtesy of Dr. Prof. Miran Špelič, OFM)).

Figure 6-199: Hieber's sketch of balance in fluids as the introduction to the description of vacuum pumps (Hieber, 1797, 66).

Figure 6-200: Hieber's description of vacuum pumps and the barometer (Hieber, 1797, 66).

Hieber later also noted Fontenelle's ideas of inhabited cosmos.[1097]

Soon after the first manuscript, in the other manuscript kept in Ljubljana Franciscan library Hieber discussed physics and added some unfinished geometrical definitions to the very end. In his discussion of the philosophy of bodies called theoretical (general) physics he described the inertial force in the terms of Newton and Bošković.

[1097] C. Hieber, Theses selectiores ex philosophia. Pedemontium, 1797, p. 26 (thesis 60); C. Hieber, Theses selectiores ex philosophia. Pedemontium, 1799, p. 13, 15 (thesis XL, XLVIII).

He filled his Universe with vacuum and accomplished some experiments on porosity of matter. In so-called "particular" part of physics, which was mostly the experimental physics, Hieber described the heat as the effect of small particles' translation according to D. Bernoulli's ideas as one of prevailing opinions of Hieber's times. In the question of light's substance, Hieber was unable to decide between the Newton's particles and Euler's undulation theory although he noted the elastic fluid emanation needed for the propagation of light. Hieber calculated the height of atmosphere and the weight of air. He contradicted the Cartesian anti-vacuum theory with modern description of air pumps and barometers which supposedly produced the disputed vacuum.[1098] Hieber supported Franklin's theory of electricity, conductors (symper-electrics), and various aspects of healings with electrifications.[1099]

6.5.6.2 Zinsmeister

Kastul Hieber (Castulus) explicitly spoke against Bošković's infinite divisibility of the substance without writing Bošković's name. Hiebel stated: *Divisio infinita veritas est in mathesi, error in physics*. It was the most disputed among Bošković's ideas and many Bošković's followers preferred to ignore it. Hiebel was apparently one of those. Nonetheless, Hiebel influenced the Carniolan Franciscan Novo Mesto professor of mathematics and Greek language Teofil Zinsmeister (baptized Franc, * 2. 11. 1777 Bavaria; OFM 10. 10. 1796; † 12. 11. 1817 Novo Mesto) who enthusiastically painted down a famous Bošković's curve anyway under Hieber's influence in his manuscript textbook.[1100]

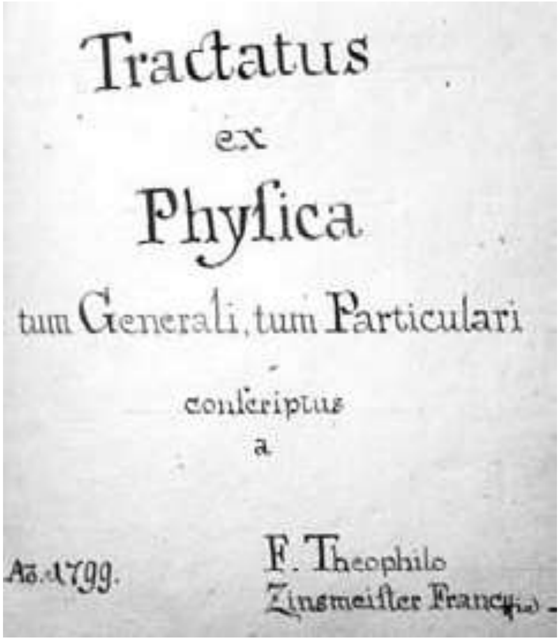

Figure 6-201: The Title page of Zinsmeister's textbook (Zinsmeister, 1799).

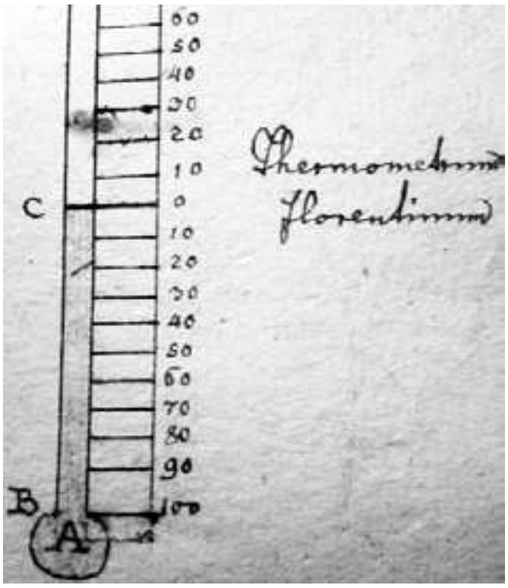

Figure 6-202: Zinsmeister's sketch of the thermometer (Zinsmeister, 1799, 1:19).

For many decades Ljubljana hosted the main Franciscan theological school, therefore its professors had also to prepare their philosophical lectures including physics almost each year. Most of their individual work remained in manuscripts which are still in the Ljubljana Franciscans' Library.

In those days, students liked to use their professor's manuscripts for the preparation of their examination. During the 18th century the professors mostly did not mail their lectures to students as the attachments to emails, they even did not use

copying machines. The students of those times preferred to use their professor's manuscripts and the most beautiful of them was accomplished by the Bavarian Teofil Zinsmeister who later between 1803 and 1816 lectured on mathematics and Greek Language in the Franciscans' Higher Studies of Novo Mesto. Teophil (Teofil) Zinsmeister taught philosophy with physics according to his probable teacher Hieber.

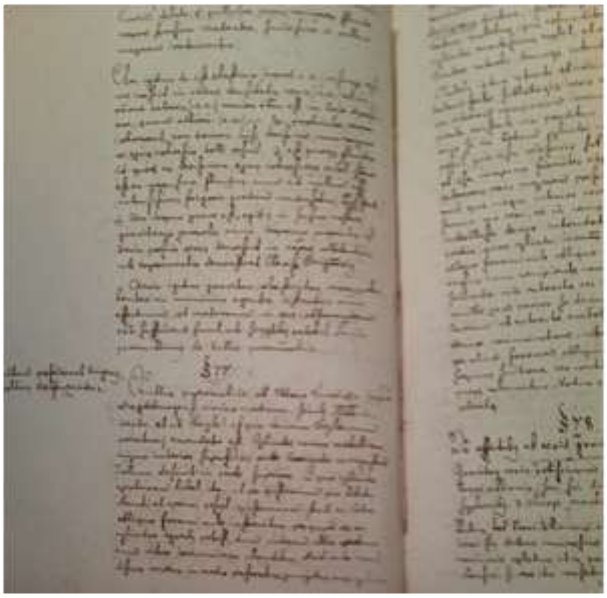

Figure 6-203: Zinsmeister's description of Boyle's *Antilia Pneumatica* and Guericke-Auersperg's Magdeburg Hemispheres. Zinsmeister subsequently added the mention of the Parisian Academician Dutchman Christiaan Huygens and other Vacuumists (Zinsmeister, 1799, 1:76).

For his Ljubljana and later Novo Mesto lectures Zinsmeister produced 169 pages long manuscript on experimental physics (*physica particularis*) and afterwards also 173 pages of theoretical physics (*physica generalis*) although the reverse order was far more common. He also produced an interesting manuscript on theology.

Zinsmeister put beautiful pictures random in his text. He began his manuscript with a paragraph on the nature of simple fire (*de natura ignis elementaris*) and discussed the penetration of light through glass, crystals, or air. That kind of introductory lectures seems somewhat unusual or extraordinary, but Zinsmeister also discussed fire later in his manuscript. He pictured the Florentine thermometer, and noted contributions of Drebell, Daniel Fahrnheit, and René Antoine Ferchault de Réaumur.

Figure 6-204: Zinsmeister's report on the barometer (Zinsmeister, 1799, 1:77).

Zinsmeister explained the phenomena of electricity relatively briefly on fourteen pages of twelve chapters without any illustrations. This seems somewhat surprising because it was just the era before Volta's breaking-through discovery and the electricity studies were extremely popular in Zinsmeister's times. He was interested in an electric spinning-wheel called *Machina Electrica*. Zinsmeister took some interests in the electrical rubbing machine. He described the electricity of fire, while in description of light and of the electricity in glass and metal he believed Benjamin Franklin and his experiments with quadrant. Zinsmeister was experimenting with electricity in nature, but unfortunately, he didn't draw his tools.
Zinsmeister specifically dealt with a lightning rod under the German title *Wetterableiter* and cited primarily the writing of Xaverius Epp (b. 1733; d. 1789) on magnetism of electricity, as well as Hungarian Jesuit Paul Mako's opinion on the electricity of the Earth.[1101] Epp and Hungarian Jesuit Mako were very popular in Ljubljana, as Jurij Vega used Mako's book on lightning rods to illustrate the questions in his final exam in 1775. In 1773 Franz Xaver Epp published the booklet for his Munich students, and Žiga Zois bought the item for his Ljubljana Library. Epp divided 146 pages of his book into 111 paragraphs about the

[1101] T. Zinsmeister, Tractatus ex Physica, manuscript 1799, 1:3, 19-21, 61, 67, 71-72.

artificial and natural electricity and added the philosophical and metaphysical examination theses.[1102] On three tables, he classified fourteen images, including a Leiden jar, lightning rods and dangerous experiments with electricity. He referred mainly to the Viennese experts, but he didn't mention the Imhof's introduction of lightning rods in Bavaria. Zinsmeister described the fires in atmosphere according to ideas of Musschenbroek.

Zinsmeister developed his description of air from Bouguer's Peruvian discovery of the changing pressure of atmosphere depending on geographical longitude. Zinsmeister cited Guericke and Boyle's vacuum experiments with whole page filled with descriptions of metallic cylinders and recipients. During one of his later readings of his own manuscript Zinsmeister added the note about the accomplishment of Dutchman Christiaan Huygens, the Frenchman Nollet, and the correspondent member of the Berlin Academy Jacob Leupold. Zinsmeister drew useful sketches of barometer[1103] but did not present any figures of air pumps even if they were very popular in those days. Besides the siphon he added the separate paragraph about the Magdeburg vacuum hemispheres according to the Mathias Gabler's theory of force (*De vis corporum*). The Jesuit Mathias Gabler was the professor of physics in Ingolstadt in 1773/74. Additionally, Zinsmeister described earthquakes, winds and sound.[1104]

Zinsmeister devoted most of his 173 pages of the theoretical (general) physics to the repulsive forces. He sketched the first fluctuation in the Bošković's graph of force distance curve and referred to Gassendi's and Nollet's subtle matter as a cause of cohesion.

Figure 6-205: Zinsmeister's sketch of the vacuum above the mercury in the barometer and in the round mercury tank (Zinsmeister, 1799, 1:78).

In the marginal notes, Zinsmeister drew the famous Bošković's curve, where he marked the intersection of the curve and axis with the letters. Because Zinsmeister signed his manuscript in 1799 it is obvious that Bošković's ex-Jesuit physics stayed in power a long time after the death of that famous Croatian and was still the fundamental idea in the Franciscan schools even if Franciscans were never in excellent relations with the Jesuits. Bošković was popular in the headquarters of the

Franciscan Friars minors who often quarrelled with the Jesuits, so the Cardinal Rode himself had to make peace among them. The fact proves again that the statements of Ugo Baldini about the quick abandonment of Bošković's ideas after his death is true just for South Italy while Bošković's physics was widely used in Habsburg monarchy several generations after Bošković passed away. Zinsmeister was extremely interested in the behaviour of Bošković's force on minimal distances between the bodies illustrated with the first fluctuation of Bošković's curve of forces.[1105]

[1105] Zinsmeister, 1799, 2:14, 16 (Figure 1), 20, 23 (Fig. 2), 28, 29 (Fig. 3).

Zinsmeister started his explanations of the forces of motion with equations and relatively intricate computations. He described cohesion with of the redistribution of the same particles of the substance on an unmarked drawing on the marginal side of his text.

Figure 6-206: Zinsmeister's description of Magdeburg Hemispheres (Zinsmeister, 1799, 1:83).

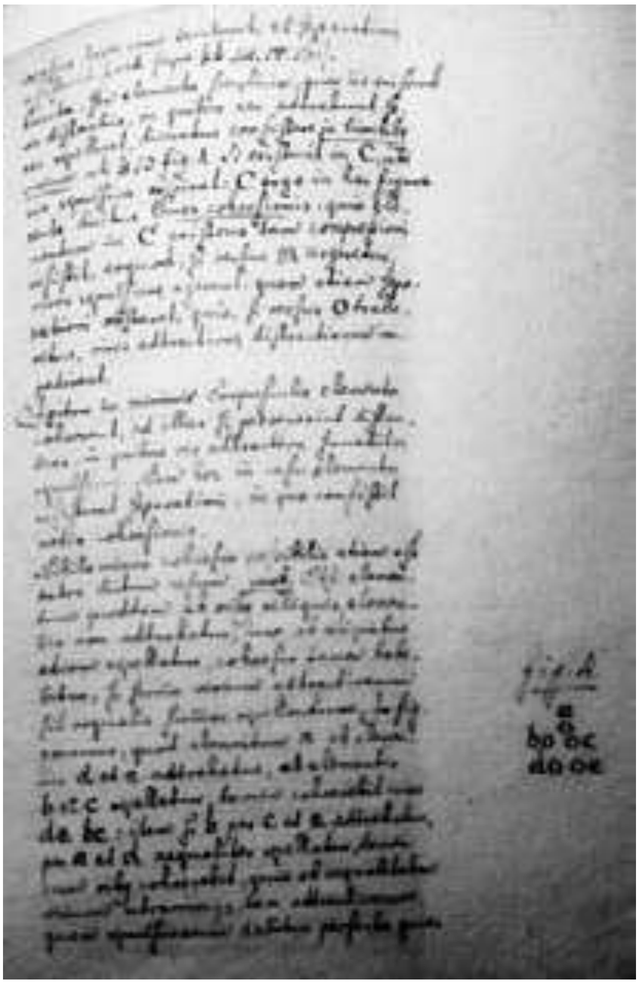

Figure 6-210: Zinsmeister's explanations of molecules (Zinsmeister, 1799, 2:39).

Zinsmeister described the matter according to the Dutchman Pieter van Musschenbroek whose measurements he used. Zinsmeister copied and summarized Musschenbroek's table of numerical values of the power of cohesion between the equal cylinders made of copper, or glass, iron, black or white marble. Zinsmeister was thinking about the cause of gravity in terms of the same speed (or acceleration) of the movement of all bodies in the vacuum. Mathematically, he relied on the central forces, which cause the circular orbit of moving bodies; Zinsmeister described them in detail.

In the third part of his theoretical physics he put in the limelight the problems of static and mechanics of translation. He examined the movement on the inclined plane (ramp) in detail. He sketched the communication vessels as well as the vacuum in a siphon made of capillaries and the cohesion of liquids in containers. He concluded his theoretical physics with more chemically coloured phenomena of crystallization and fermentation,[1106] which must have come in handy to Lower Carniola (Dolenjska) lovers of good droplets of wine.

Figure 6-211: Zinsmeister's examination of the connected vessels and vacuums in the siphon (Zinsmeister, 1799, 2:154).

Zinsmeister cited the Jesuit Horvat's physical textbook which immediately on the first whiteboard full of folding images offered sketches of vacuum devices. Already in 1771 Horvat's textbook belonged to the Franciscans' Library of Sveta Gora near Gorizia Town,[1107] where the famous Slovenian poet Valentin Vodnik used it soon after he ended his school years in Ljubljana in 1781. In 1786, the Emperor Josef II suppressed the Sveta Gora monastery and Horvat's and other beautiful books bind in leather were transported to Ljubljana Franciscans' Library where Zinsmeister had read them. The Croatian Ivan Horvat was one of the most important supporters of Bošković's ideas in the University of Trnava which was moved to Pest in 1777, and seven years later to

[1106] Zinsmeister, ibidem, 2:24, 36, 39 (Fig. 4), 43, 68, 71, 111, 147, 152-153 (Fig. 34-38), 155-156, 159, 167, 169.
[1107] Zinsmeister, ibid., 1: p. 169; Joannis Baptistae Horváth, *Instutiones Physicae Particularis*. Tyrnavia (FSLJ-21 f 9), 1770, p. 477.

Buda. The Ljubljana Franciscans had bind Horvat's textbooks into the solid vellum whose whiteness later darkened because it was widely used. One of the frequent users of Horvat's books in the Ljubljana Franciscans' Library was Zinsmeister's colleague Ivo Bonelli who taught in Innsbruck but eventually died on duty in Ljubljana taking care of injured soldiers in the eve of the Napoleonic Illyrian provinces. The Siebenburgen (Gradišča) Croat Ivan Horvat was one of the most important proponents of Bošković's ideas. Together with his older colleague Jaszlinszky, he lectured at the University of Trnava. The Ljubljana Franciscans bind Horvat's textbooks into the white hard parchment which is now smeared and worn out from frequent use.

Of course, Zinsmeister was not the only Franciscan who was attracted by the discharge of the vacuum at the time before the cathode ray tubes when the steam engine was the only industrial use of the empty. In 1739, Slovenian southern Franciscan neighbors in the town of Fojnica of Silver Province of Bosnia (*Argentina*) created an interesting physical manuscript on the movement in the vacuum under the domestic goose pen which was used by the Vukovar Franciscan professor of philosophy Joannis Velikanović (Ivan, 1723 Slavonski Brod, 1723-1803 Vukovar) and after him by Francisco Vrasevich (Vrašević) of Fojnica with a dated proprietary entry on 9. 12. 1739.[1108]

6.5.7 Conclusion

As the young Franciscan in Trsat and Klanjec in today's Croatia, Žiga Škerpin learned to love mathematical and technical sciences. He soon became the Franciscan leader with many administrative tasks, and therefore he was unable to fulfil his early mathematical-technical fashions. Anyway, he used his youthful knowledge for the expert acquisitions of contemporaneous and older literature for the Ljubljana Franciscans' Library to enable the scientific research of the future Franciscan generations. His efforts helped his fellow Franciscans of Novo Mesto to organize the public lectures on lower lever in 1746 with some mathematics included, and even the internal Franciscan lectures on mathematics and physics on the higher level of Novo Mesto philosophical studies after the year 1762. The schools of Ljubljana equally needed good library which Škerpin made use of. Škerpin's book collection enabled Franciscans to become excellent lecturers on mathematical and technical subjects. As did Ljubljana Jesuits a century earlier after the opening of their higher philosophical studies in November 4, 1704, also the Franciscans had to use the foreign imported teachers to begin their newly established schools. The Bavarian Franciscans Hieber and Zinsmeister completely fulfilled the task in the late 18th century.

The Franciscan scientific efforts in Ljubljana brought several new aspects in Central European networks. In many ways, the Ljubljana Franciscans' Library preserved the feeling of old times reading societies of the mid-European lands. During the reforms of Emperor Josef II, the Ljubljana Franciscans' Library was moved across the Ljubljanica River in the monastery of recently suppressed Augustinians. The Franciscans collected the valuable treatises in their library for long centuries but only their leader Žiga Škerpin acquired enough books to enable the successful teaching of the early new sciences. He acquired an extraordinary great amount of the contemporary and older philosophical literature for the Ljubljana Franciscans' Library in the times when the philosophical literature also contained mathematical, physical, and biological sciences in the librarian's expert group numbered ten. No less important were Škerpin's acquisitions in the librarian's expert group numbered twelve containing the medical and pharmaceutical literature. In 1744/45, Škerpin ordered renewed binding of many books which he inherited from his precedents in Ljubljana Franciscans' Library, although that act is valued differently by modern researchers of Ljubljana Franciscans' Library because older covers and some marginalia were lost in the process.

It is believed that Škerpin got many of his new leather-bound beauties almost for free during his frequent travels through Italy and Spain, because he knew very well how to behave in the learned European societies. He brought so many newly issued items to Ljubljana that he had to rebuild the new library facilities in the Franciscan Monastery on today's Vodnik Square in Ljubljana. It is sorry to say that Škerpin's building did not benefit much

[1108] Hrkać, S., *Filozofijski manuskripti na latinskom jeziku u Bosni Srebrenoj*, Ziral, Mostar 1998, 234; Fojnica OFM Monastery Rk. 44 (manuscript).

his Franciscan descendants because Šemerl rebuilt Škerpin's Franciscan monastery to serve the purposes of Lyceum few decades after Škerpin's death. Much more useful were the books which Škerpin acquired, although the domestic Franciscans were not always educated enough to use them for their lecturing. To fit the demands of the day the Carniolan Franciscans had to import the lecturers from other Franciscan provinces, especially from Bavaria, because the Bavarians knew better the new scientific inventions. With his efforts Škerpin paved the way for the Bavarians Franciscans Zinsmeister, Hieber and others who began the modern mathematical-technical lecturing in Franciscan schools nearly half of a century after Škerpin's death. Their success could be valued by the manuscripts they left, also by the books they used for their writings. In many aspects, we could suppose that the Franciscan lectures on mathematical and technical subjects were not at all inferior compared with the lectures of their more famous Jesuit contemporaries or later lay professors.

The Ljubljana Franciscans for centuries guarded the remains of the first Carniola vacuumist Janez Vajkard Auersperg (Turjaški) under the walls of his church-chapel on today's Vodnik's square, by funny coincidence named after the Franciscan Valentin Vodnik. One way or another, they also began their interesting research in modern vacuum techniques. They have purchased modern literature about them. For their students, the vacuum was discussed in their manuscript textbooks that were not able to get through the printing machines.

The Franciscans of today's Slovenia taught in secondary public schools only in Kamnik and Novo mesto. Nevertheless, they were well supplied with first-class physical literature related to the empty, which was already examined at the dawn of vacuum experiments by Capuchin Valeriano Magni and the Minim priest Marin Mersenne. The Franciscan Scotus' approach to the vacuum suited Valeriano Magni or Torricellian experimental approach much better compared to the ideas of St. Thomas Aquinas in the Jesuitical Suárez' version. There was the huge profound difference between Valeriano Magni's anti-peripatetic ocular observations of vacuum and much more reserved vacuum-related enthusiasm in Kircher's Jesuitical networks or in Janez Vajkard Auersperg's leading political headquarters. The official Papal opinion about vacuum possibilities was much more patient compared to papal bans against Copernicans, atomism, or early Cartesians which enabled different Catholic interpretations of the results of early vacuum experimentation. The controversial division between vacuists and pleinists left much more space for the intermediate opinions like the one of the atomist Descartes compared to similar disputes resembling the earlier Copernican quarrels or the later antagonisms among Nollet's or Franklin's number of electrical fluids with the shapes of lightning rods included, Stahl-Lavoisier's phlogiston-caloric, or Galvani-Volta's sources of electricity. It was quite possible to develop a solid vacuum technique and retain the doubts in complete void of a vacuum. Unlike the relative outcomes of other similar quarrels, the quest for absolute vacuum never ceased to be an unresolved Gordian knot puzzle.

6.6 Valvasor about Vacuum and Thin-walled Sculptures

6.6.1 Introduction

After studying the vacuum books of the Auersperg prince's library and similar Franciscan treasures, it's right to describe Valvasor's book treasures as he became ~~a~~ heir of the Auersperg's Baroque Spirit. Many books in Valvasor's library and his own research was focused on vacuum technique. In many ways, Valvasor surpassed his example of the provincial governor Wolf Engelbert Auersperg because Valvasor purchased more extensive readings in foreign languages from faraway countries. Valvasor was particularly interested in Boyle's vacuum pump. While Wolf Engelbert Auersperg and his brother Janez Vajkard Auersperg's pioneering vacuum researches followed their personal acquaintances with Guericke and V. Magni as well as the correspondence with Kircher, Valvasor's mature opinions about vacuum emerged from his correspondence with Halley.

Valvasor wrote his major studies of the properties of materials in a total of nine volumes of his Lumen naturae and Flos Physico-mathematicus. Both manuscripts were lost after the sad Valvasor's debt settlement needed to avoid bankruptcy. Therefore, Valvasor's knowledge of vacuum and foundry techniques can only be estimated from three sources: by reading his books sold to Zagreb metropolitan library, reviewing scientific instruments listed in his legacy in Krško, and studying his thin-walled sculptures.

6.6.2 Thin-wall Statues

The foundry business was not foreign to Valvasor's Jesuit teachers in Ljubljana, but Carniolan Janez Vajkard surpassed them. His knowledge of metallic materials has increased his interest in alchemy, mainly under the influence of the Royal Society of London and its important member Robert Boyle.

Valvasor bought the stand and pillar, and according to his order Wolf Weisskirch(n)er from Salzburg made the mold of St. Mary's statue.[1109] Prior to the Christmas holidays just before midnight on 16 December 1681, Valvasor casted his sculpture by his innovative foundry procedure in front of the Karlovac Gate on Karlovška Street no.15, where Krištof Schlag(s) established itself as the forerunner of the later bell-foundry family of Samassa.

On the Good Friday of 27. 3. 1682, the statue was transferred in front of the nearby Jesuit church of St. Jacob within the Jesuit College. There was no road Dolenjska cesta in those times, so traffic stop was not needed. The architect Marcello Genovese (Genevese) lifted Valvasor's art on a pedestal, which was built in the meantime during wintertime. The ceremonies were attended by the rectors of Jesuit colleges of Gorizia, Trieste and Rijeka, and the news of Valvasor's invention quickly spread.

Valvasor reported to Secretary of the Royal Society Thomas Gale about his Ljubljana Marian statue and about new procedures for its casting; Valvasor earned extraordinary attention as rarely any Carniolan inventor sooner or later. In 1687, E. Halley at Phil.Trans. published Valvasor's letter to the secretary Thomas Gale about a new way of casting metal sculptures with a beautiful sketch of a statue of god Pan with panpipes. Probably Valvasor also casted Pan, although today we do not know where he put that statue.

[1109] SBL, 3: 220.

Valvasor's friend Halley has edited Phil.Trans. between 1685-1693 and published there other Valvasor's works. The previous editor of Phil.Trans. Robert Hooke was angry and felt neglected, as it was his old way of behavior. Hooke was jealous, so, he cruelly hinted that Valvasor's inventory of thin-walled casting does not bring anything new, except the use of other chemicals, mostly one-third of the "bismuth" or zinc brass, which the pouring of melted alloy easier.[1110] In fact, this novelty was irrelevant only at a first glance.

Hooke and the master of the English Foundry Guild, however, approved the publication of the Valvasor's procedure after the art critics Dr. Aglionby compared Valvasor's novelties with the practices of London craftsmen.[1111] Valvasor's peer Aglionby was a member of the Royal Society, and he also corresponded with the famous Locke. Valvasor was inspired to a certain extent by German potters as well as by the Japanese alloys about which he learned during his love adventures in today's Tunisia and Libya in the summer of 1669. Additional to the chemical composition of the alloy, despite of Hooke's despair, Valvasor improved the distribution and design of the casting channels,[1112] since he was well acquainted with his business. Today, we do not know whether a pump was used when casting, which, in view of Valvasor's knowledge of vacuum technology, is quite likely.

Thomas Gale (* 1635/1636 Scruton in Northern Yorkshire; † 1702) was slightly older than Valvasor. He grew up as a single son, studied in Westminster, and in 1655 he entered the college of the Holy Trinity in Cambridge just before Newton. Gale graduated in 1659 and obtained a master's degree three years later. The university has published some of his glorifying verses upon the death of Oliver Cromwell, which brought him a reputation in society. In 1666 he became a professor of Greek language in Cambridge, and in 1672 he became a Headmaster in the school of St. Paul, where Valvasor's later friend Edmund Halley was among his students. On 6 December 1677, Gale was elected to the Royal Society of London,

[1110] Reisp, 1987, 8; Paulin, Trbižan, 1996, 264.
[1111] Reisp, 1983, 176.
[1112] Trbižan, 2003, 177, 183.

almost exactly a decade before Valvasor, and in January 1686 Gale became a secretary of the Society. Gale's assistant became Halley, who performed that duty until 1699, and from that time Halley knew Valvasor's letters sent to London. A few years later, Halley traveled through Istria and Kvarner bay, looking for an appropriate port for the disembarkation of English and Dutch military during the War of the Spanish Succession; unfortunately, his friend Valvasor died a decade earlier. According to the king's order, Gale listed so well all the monuments in London that the city rewarded him with a plaque. As a specialist for monuments, he was especially interested in Valvasor's casting of sculptures. Already at the beginning of the 17th century, gypsum molds were poured with a liquid clay mixture for the richer Brits, who wanted to get rid of an annoyance from that funny room to where even the emperor was walking on foot. Such toilet bowls were very expensive, and the water was still absorbed in them.[1113] That's why Gale and his hygienic colleagues searched for different new materials and Valvasor's similar innovative casting processes. Foundry was well developed in the immediate vicinity of the Royal Society's headquarters on the eastern end of London. In 1570, Robert Mot founded a foundry that later became the Royal Whitechapel Bell Foundry. It was mainly based on the casting of London Big Ben and the American Pennsylvanian Liberty Bell of 1752. The center of English iron-foundry was in the valley with the famous name of Ironbridge; there they developed the iron industry, which soon after Valvasor's death made great progress by Abraham Darby's invention of the use of coke to produce pig iron in a blast furnace in 1735.[1114]

The chemical analysis and electronic microanalysis have shown that the contains of the alloy of Valvasor's statue of St. Mary at St. Jakob's has only a hundredth of a percent of bismuth, and therefore almost 16% of zinc. As if the Baroque master had learned the modern experiences that exposed bismuth as a dangerous fragile agent in copper alloys, where it should not exceed 0.005%. By adding zinc, 4% of lead and over 2% of tin, Valvasor reduced the melting point of the alloy by 120°C. He received the "most liquid" substance for casting thin-walled sculptures and overtook the achievements of all his contemporaries. As an experienced foundry expert, he developed a sophisticated feeling for the beneficial influence of smooth surfaces of the channels to better the flow of the alloy in the mold of the statue. He took advantage of the important effects of surface coating, so he was able to avoid unwanted wax components in coatings. He certainly got raw materials from the local Carniolan and neighboring places, although he did not publish the details. On today's Slovenian soil, twenty-six iron and blast furnaces and blast furnaces worked in Valvasor's time. In Carinthia, they operated already in the 15th century. Valvasor probably obtained his mineral zinc carbonate (calamina, zinccum, smithsonite), from Rabelj (Cave del Predil, Raibl) in Carinthia-Tarviso. He might have obtained a copper and zinc alloy"golden copper (aurichalcum)" in Cerkno, where the copper ore was dug in the 15th century. Shortly before Valvasor castings, Hans Sigmund Ottenfeld was granted permission for the lead mine in Črna na Koroškem (1665). Four decades before Valvasor's birth, the miners of Counts Thurn-Valsassina began digging lead in the northern Pliberk and Peca mountain, also in the Iron Caves (Železna Kaplja) and Rabelj.[1115]

The impressive expenses for Valvasor's St. Mary's statue were settled by Carniolan provincial Estates General, and even the baron Janez Vajkard received some gold coins for his pocket. He bought the manor Bogenšperg, but he was never able to pay off all the purchase, so that he urgently needed additional incomes. Five years after his English publication in London his casting process of metal sculptures was translated in the first volume of the new magazine *Acta Eruditorum*, which, at the initiative of the famous scholar Leibniz, began publishing in Leipzig. The Latin publication in the first issue of this famous magazine shows, the importance of Valvasor's idea among the foreigners, while he prematurely died in Krško without much money left. Nobody is a prophet in the homeland, and especially not in Carniola. Valvasor wanted the outmost liquid melted alloy, which he poured into the intermediate space of the covered basic form of the statue. In that regard,

[1113] Lambrozzi, 1994, 93.
[1114] Ruschitzka, 1985, 49.
[1115] Paulin, Trbižan, 1996, 263, 264, 267-268; Paulin, 1998, 63, 65, 67, Šorn, 1984, 167; SBL, 4: 82.

Valvasor carefully measured the increment of the size of the statue model due to the added layer of metal. His quality of the cast was, of course, not comparable to thin layers and thin films based on modern vacuum processes of surface overlapping, which were still unknown to Valvasor.

When the statue was made, Valvasor removed the mold and the tiny channels through which he poured the alloy. The cut-off casting system was prepared for "reuse";[1116] he would certainly not have done this if he did not get many other sculptures done, although currently we know only the one in Ljubljana.

During his reporting period to the Royal Society, Valvasor has not yet able to make any sculpture larger than nine feet (3 m) but he did not doubt that he could also face higher challenges.

Valvasor announced that he will cast the statue of Emperor Leopold on the horse. Valvasor intended to immortalize the emperor in a supernatural size to glorify his visit to Ljubljana in 1660. The Emperor had already agreed his castings with the Carniola's provincial states (Estates General),[1117] who were willing to cover the costs of Leopold's monument. Valvasor also awaited the end of the Turkish threat, which began in July 1683 with the Turkish siege of Vienna. After lunch on August 7th, 1683, Valvasor as the captain of one fourth of Carniolan troops hurriedly left Ljubljana as the commander of the Carniolan troops defending the endangered Styria.[1118] He postponed his readings of Boyle's book on vacuum techniques for a few months to replace his pen with a swashbuckling sword and a gun. On the feast of all the saints, he was already home, but he did not cast the planed Leopold's statue, because Valvasor was under the earth already for a long time at the end of the "Viennese War" in 1699.

Valvasor description of the process of casting thin-walled sculpture was the first internationally recognized technical document of the Carniolan inventor in the field of metallurgy and engineering in its entirety.[1119] In any case, the statue of St. Mary was not the only product of an experienced Valvasor's castings, although others are still unknown to us.

6.6.3 Galileo's Circle in Valvasor's Networks

Valvasor was aware of the technical merits of Galileo's followers. Valvasor advanced his knowledge of foundry and vacuum techniques in his carefully selected home library, and he learned a lot during his many years of youthful journeys. He also read older opinions on the vacuum, including Sebastian Fox Morcillo of Seville, who studied classical philosophy in Leuven (Louvain) in the south of then Spanish Netherlands. The Spanish King Philip II named him as the guardian of his son, Carlos, but Fox Morcillo sadly drowned on his way to a new job. Valvasor read the first posthumous reprint of Fox Morcillo's philosophy of the nature of Aristotle and Plato, dedicated to Fox Morcillo's intended employer Philip II. In the eleventh chapter of the first of his five books, Fox Morcillo described the infinity and vacuum. According to Parmenides, God had the opportunity to create infinity, but above all, Fox Morcillo referred to Plato's Timaeus and rejected the empty space without a substance.[1120]

Valvasor was interested in the works of Galileo's predecessor Baldi, who studied mathematics at Padua together with Galileo's friend Marquis Guido Ubaldo del Monte. In 1570, the teacher of mathematics Commandino asked Baldi him to translate Heron's study of vacuum devices from ancient Greek to Italian. He published it only in 1589 with an introductory study of the history of mechanics. Only the translation enabled the development of Heron's ideas about the reality of an empty space in Galilean visions of matter composed of atoms separated by a vacuum. Valvasor bought the Italian translation of Heron, published by Federigo Commandino's student Alessandro Giorgio of Urbino (1592); he additionally received Agathus Cario's German adaptation of Commandino's Latin translation publishedin the year 1688.

Valvasor also kept Baldi's most important work on Aristotle's mechanics, published posthumously in 1621. Baldi even attributed to Aristotle a task with a emptied receiver; this was certainly not the

[1116] Paulin, Trbižan, 1996, 267.
[1117] Radics, 1910, 146.
[1118] Reisp, 1983, 164.
[1119] Paulin, Trbižan, 1996, 263.
[1120] Fox-Morzillo, 1560, 28^r, 29^r, 30^v-31^r.

original thought of Aristotle, who did not even approve of the vacuum. Baldi returned to the vacuum again by thinking about the gravity fed water system at the end of the book.[1121]

The Jesuit Francesco Lana Terzi proved to be among the best Kircher's students at the Roman College. Valvasor bought the first two parts of Lana's Lessons on Natural History, while sixty years after the printout Bernard Ferdinand Erberg acquired all three parts for the Jesuits of Ljubljana. The Franciscans of Ljubljana also used Lana's book. The main admirer of Lana's vacuum aircraft was Frančišek Jožef Thallmainer who became a head of Bishopric library of Ljubljana (today Seminary Library) in 1742. Thallmainer owned at least 476 books of his own including two Lana's works. Lana accurately described Torricelli, Boyle's and other experiments with gases and vacuum. He trusted Kircher and Schott, but criticized Galileo.[1122] In 1670, he excelled by his plan of evacuated copper-balls aircraft and became a fellow of the Royal Society of London several years before Valvasor.

6.6.4 *Boyle's Vacuum Pump for His RS Fellow Valvasor*

Valvasor bought six Boyle's prints, among them the Geneva Collection (1680) in thirteen volumes with twenty-five major books. Valvasor's enthusiasm for Boyle can be expected, as three Boyle works were also offered in the new Ljubljana bookkeeper Mayr's shop in 1678. Valvasor was fourteen years younger than Boyle; during his stay in Paris and England[1123] in the time of Boyle's final resettlement from Oxford to London in April 1668, Valvasor became acquainted with Boyle's vacuum experiments.

Valvasor bought Boyle's Hydrostatic Paradox (1670) with three nice groups of images of capillaries in the vessel, the pressing of liquids and the consequences of the difference in pressure. Boyle's experiments were repeated by Valvasor at Bogenšperg to check the operation of the alleged siphons under Lake Cerknica, which Valvasor's friend Halley then demonstrated in front of the London Royal Society in honor of Valvasor's election among new members in 1687. Boyle lived in Pall Mall in those times, but he gradually withdrew from his public engagements, ceasing his communications to the Royal Society. Valvasor as the only Carniolan member of this famous Society witnessed the extremely high Londoner respect of Carniolan Baroque science and technology.

According to an address to the reader and in the preface (1680), the Hydrostatic Paradox was the continuation of Boyle's "Tractatus de Aëre" (1672). It was sold by Mayr in Ljubljana, and after Boyle's death it was translated into English. Boyle compared the pressure in the liquid with Torricellian experiment with a vacuum above a mercury-filled tube. In his address to the reader, Boyle rejected Hobbes's attitude towards a vacuum, which Boyle also deleted as a political antagonist of the royalist Hobbes. All four Valvasor's books from Boyle's Geneva collection (1680) were devoted to vacuum experiments, along with two others in the Geneva edition of 1683. Boyle wrote the first and longest vacuum booklet as anthology of his letters mailed to his nephew Carl Count Cork (1680). Boyle added to them a decade earlier Hydrostatic Paradox with two groups of images placed between two panels of sketches of vacuum devices. This was one of the few illustrated booklets in Boyle's Geneva collection, from which Valvasor learned his new views on the secrets and on the science of empty. Boyle began with Torricellian and Guericke's achievements, but he skillfully promoted Hooke's abilities and completed forty-three experiments on December 20, 1659,[1124] when Valvasor already left his schooling and started a full decade of his youthful adventure journeys.

Boyle also included his second vacuum booklet *Defensio doctrinae de eatere et gravitatione aeris* in his Genevan anthology of 1680, which Valvasor also bought. Boyle misspelled the name of Blaise Pascal as Monisieur Paschal; Gassendi informed Boyle about Pascal's work which might have caused the misspelling. Boyle valued Pascal's vacuum experiments;[1125] so, it is all the more surprising that Boyle's colleague FRS Valvasor did not buy Pascal's works as Valvasor had opportunities for his shopping during his travels in France and England. Valvasor arrived in France

five years after Pascal passed away[1126] when everyone spoke of his prematurely dead genius. Pascal's descriptions of experiments were bought by Valvasor's colleague in their joint debates in Wolf Auersperg's palace, Baron Erberg, for his library in Ljubljana, later transferred to the nearby Dol.

Boyle devoted his third vacuum booklet to early experiments with Machina Boyliana. He referred to his New Vacuum experiments, to Mersenne's Compression Researches and to the measurements of Florentine Academics. Boyle invoked the most important Englishmen of his era to witness his vacuum researches in the Pall Mall rooms of his elder sister, who shared his scientific pursuits. The gentlemen guests gave to his reputation an additional weight, as it was a nice habit of those days. He described the freezing of steam by lowering its temperature when pressing under the weight of a mercury column. In his critique of Hobbes, he cited his older experiments in a mercury barometer.[1127] Boyle rejected Hobbes by Guericke and Torricelli's experiments. Boyle devoted his final ending chapter to the storage of foods in a vacuum, which particularly impressed Valvasor. In June 1670, Boyle saved a pint of French wine in a vacuum. In July 1671 he took out and assured his friends gathered around his happy well-dressed table that the wine retained purity and color. Valvasor was not invited as he left England earlier. Valvasor and his teenaged sons in Bogenšperk did not drink much wine despite the care of Valvasor's first wife. Nevertheless, Boyle's idea of storing wine has deeply touched Valvasor's soul along the Sava riverbanks full of vineyards.

In 1682, in Geneva Boyle communicated the continuation of his physics-mechanical experiments with excessed pressure of compressed warm air including poor animals put in vacuum. In the study of overpressure, the process of pumping out of the vacuum was reversed, which allowed the steam engine to develop in those and later times. With the help of inventor Denis Papin, Boyle experimented between 11 June 1676 and 5 September 1677 and illustrated his accomplishments on six full-size plates at the end of his book. Like Boyle, Papin was also successful in his dealings with overpressures and vacuums.

[1126] Reisp, 1983, 84.
[1127] Boyle, *Tractatus*, 1680.

After his settlement in Bogenšperk, Valvasor bought the first volumes of Phil.Trans.[1128] and among them read a report on the first Hooke's and Boyle's experiments with a vacuum pump in front of the Royal Society on 15 February 1665. In Mayr's bookshop in Ljubljana, Valvasor studied Boyle's reports of very cruel experiments with ducks in the emptied vacuum vessel[1129] that would of course, trigger a lot of severe protests in the modern Animal Protection Associations. Valvasor immediately began to write to the secretary of the Londoner Royal Society Gale. Valvasor proudly wished to publish his own research in Phil.Trans.

In addition to the collected works, Valvasor also bought Boyle's discussion of luminescence Noctiluca (1682), which was particularly close to Valvasor, since the first researchers of the luminescence came out completely from alchemical traditions. Boyle first described Baldi's hermetic phosphorus, and then the work of German Daniel Krafft. He observed the shimmering in a vacuum and summarized the process of producing luminophore Noctiluca (Lampyris *noctiluca* worm) according to the habits of then alchemists.[1130] Boyle dealt with luminescence in the air and even in ice also in vacuum of *Antilia Pneumatica*. Boyle published his own letters as then popular kind of discussion. He concluded with chemical paradoxes in response to the Jesuit Kircher's (1646) claims which Boyle of course hated as a devoted Protestant. Boyle wrote in the form of letters to Dr J.B. and ended up with chemical paradoxes. Boyle's interest in luminescence was also the answer to Kircher's (1646) allegations about it. Like Hobbes, Kircher did not believe that the vacuum pump indeed removed all the substances. Of course, Boyle disliked the fierce Jesuitical versions of Catholicism.

Boyle quoted Kircher's description of luminescence (1646), which was purchased by both Volf Auersperg and Valvasor in Boyle's book on experiments and Reflections. The Jesuit Procurator Francisco de Florencia (1619/20 Florida Espanola-1695 Mexico) sent to Kircher a dissolved

luminescence material from Mexico so that Kircher could pass the news to the Emperor himself. Kircher used the data of Monardes who was known for his first description of tobacco.

Boyle referred to Glauber as far as the colors of metals were concerned. Valvasor had so greatly respected Glauber that he had collected as many as his twenty-seven books; certainly, also because Glauber spent several years in Vienna. Boyle concluded with a description of the luminescence of Bologna stone and especially of precious stones.[1131] After a hundred and five pages about the theory of matter consisting of particles, Boyle made ten experiments described in his last forty-two pages. In the sixth part he studied Glauber's salt, and in the ninth part he referred to Helmont and Paracelsus' Alkahest, which in many ways became the basis of Boyle's thoughts.[1132] One of the discoverers of phosphorus, Kunckel, later criticized Alkahest with the conclusion that no vessel was able to keep it. Similar problems bothers the modern fusion reactor as no container is strong enough to withstand its heat. A phosphorus researcher and Viennese economic adviser Becher also discussed Alkahest; Valvasor has acquired a dozen of his books, while Wolf had only three. Valvasor bought four more major Kunckel's works in German Language, while Wolf had died before they were issued; the first professional Idrija pharmacist E. Freyer also acquired Kunckel's book in German Language. Valvasor was very interested in luminescence and asked RS in London to send him the instructions for production of phosphorus of all species, according to the report by Irish bishop-mathematician George Ash,[1133] a friend of the writer Jonathan Swift who loved to ridicule RS. Valvasor also tried to build a luminophore from a kind of glow worms, but the resulting substance was not persistent. In Valvasor's legacy in Krško, after his death, a "brass black device in the shape of a night-lamp"[1134] was also recorded, which was also commonly used in Boyle's books under the name of luminophore Noctiluca. Unfortunately, the inventory commission members did not describe the composition of Valvasor's luminophore in more detail.

6.6.5 *Boyle's Antagonists*

Valvasor bought Cabeo's Magnets dedicated to the French King Louis XIII. Cabeo attributed the magnetic phenomena to the alleged movement of the masses of air, which were first expelled by the electricity, and then the air returned to its original position and pulled enough particles with it. Both Boyle and Galilean heirs at the Florentine Academy Del Cimento investigated the vacuum to confirm or disprove Cabeo's assumptions. In the second book, Cabeo rejected the opinion of the physician of Queen Elizabeth W. Gilbert on changing the electric attraction in moisture and especially in water. Cabeo specially sketched the attraction between the magnetic sticks under water.

Figure 6-214: Cabeo's testing the operation of a magnet under water in Valvasor's collection (Cabeo, 1629, p. 186). (Photographed in the Bizzell library of Oklahoma University).

Later, Cabeo, together with his Ferrara fellow citizens, opposed the hydraulic ideas of Galileo's student Benedetto Castelli on the supposed regulations of the River Reno, supported by Pope Urban VIII. As a Jesuit, Cabeo did not recognize the vacuum as it was supposed to disturb the local movement,[1135] although Cabeo also published a great book about meteorology.

Figure 6-215: Cabeo's attempts to break the magnet in Valvasor's collection (Cabeo, 1629, p. 81). (Photographed in the collection of the history of science with the permission of the University of Oklahoma).

Valvasor read the continuation of Cabeo's vacuum survey of the other Jesuit, Kircher, as Valvasor owned all Kircher's works. Kircher’s magnet for lifting large weights impressed Valvasor, who acquired his own powerful magnet. With it, he could lift the weight of the iron which forty times surpassed the weight of the magnet. Upon his death, Valvasor left his extraordinary magnet in his house in Krško:[1136] it would be interesting to know where this miracle of science is hidden today.

Kircher was interested in the operation of the magnetic force in a vacuum. Kircher nicely illustrated his vacuum device and showed how diluted air draws water from the container up in the tube. Water then pours through the periphery of the container on the floor or even back into the container as a nice kind of perpetuum mobile, which later turned out to be an illusion. Kircher called those fountains in his third book the "hydraulic machines".[1137]

Valvasor bought twelve Schott’s mathematical-technical manuals at his most complete Carniolan collection of Kircher's works, since Schott was the most important Kircher student. Valvasor's was interested in the invention of a vacuum pump, which Schott first described and illustrated.Valvasor quoted Schott's works. He also quoted nine Kircher books in Valvasor’s Glory (Slava) as Kircher was the author whom Valvasor used the most. Valvasor's role model Volf Auersperg had eight Schott’s works: of course, just like Valvasor, Volf (Wolf) Auersperg acquired all those Schott’s writings connected with vacuum techniques. Wolf's brother, the prince Janez Vajkard Auersperg, assisted Guericke in his vacuum experiments in Regensburg, and Janez Vajkard Auersperg closely collaborated with Kircher. Six letters sent from Janez Vajkard Auersperg’s rooms to Kircher in Rome were

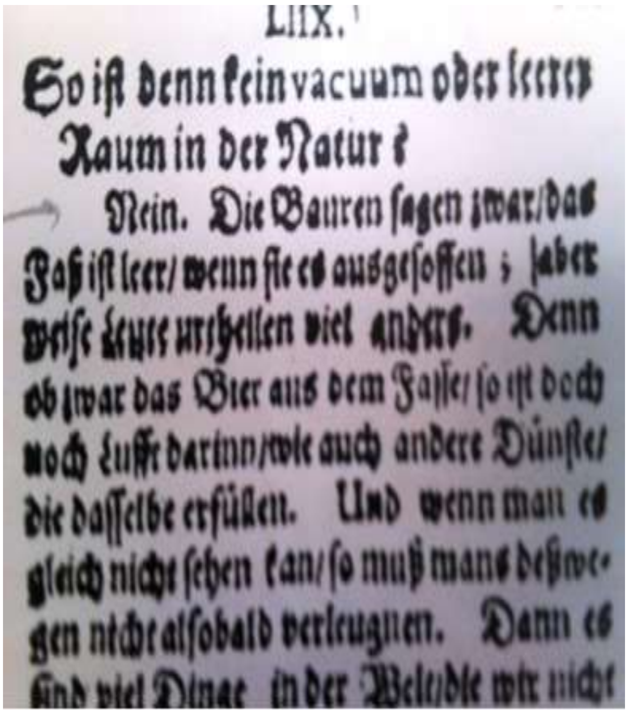
preserved;[1138] of course, he wrote to him in Latin language, because Kircher would not understand Slovenian scripts. Janez Vajkard Auersperg sent the second letter just before making a famous experiment with horses and vacuum hemispheres in Regensburg with Guericke, and he wrote his last letter mailed to Kircher from Ljubljana a little before Valvasor settled in Bogenšperk. Kircher's and similar fundamental scientific researches were clearly closer to Baroque Ljubljana, than they are today.

Valvasor acquired Voigt's book of Wasting the Time for Physics in its second edition. An educational booklet with two hundred responses to interesting physical and biological questions was written just nice for Valvasor's noble soul. In his preface, Voigt devoted his work to Wittenberg's professor of medicine the Lutheran Daniel Sennert, whose discussion of heat and fevers Valvasor read in the collection of his model Wolf Auersperg. The rector of the main school in Güstrow, Voigt, discussed opinion of Valvasor's chief associate the Nurnberg native Erasmus Francisci, who was at that time one of the most popular writers of scientific literature. Certainly, the Franciscans of Ljubljana also read Erasmus Francisci's books.

Voigt discussed acoustic experiments with the Dionysius flute. Voigt compared the smallest animals with atoms. He supposed that in a grain of smoked aromatic camphor one could find a million times more atoms than we could even count. Despite of Boyle's and Guericke's experiments, Voigt did not believe that any perfect vacuum is attainable. Was he wrong?

6.6.6 Conclusion

Valvasor did not complete his schools without higher university studies; he preferred to put his school bag in a corner and enjoy his fourteen years of youthful travels around the world. So, he became acquainted with the leading ideas and at the same time with the most expensive physical devices of his era, namely, a vacuum pump. He correctly realized that the focus of research on vacuum techniques had moved to English Boyle's networks; Valvasor therefore bought all Boyle's works on a vacuum pump and became a member of the Royal Society as the first and only Carniolan and Slovene of those times. There Valvasor became a friend of Boyle's colleague Halley. Valvasor spent his time in studying the properties of new materials. He crowned his pursuits with an ingenious procedure for casting the best thin-walled sculptures of his time, which brought his glory throughout the whole Europe. Does he deserve a memorable inscription under his Mary's statue in Ljubljana, a unique monument of Carniolan and Slovenian knowledge that would glorify the master for many centuries, as the Jesuits of those days stated?



LIIX.

So ist denn kein vacuum oder leerer Raum in der Natur?

Nein. Die Bauren sagen zwar/das Faß ist leer/wenn sie es ausgesoffen; aber weise Leute urtheilen viel anders. Denn ob zwar das Bier aus dem Fasse/so ist doch noch Lufft darinn/wie auch andere Dünste/die dasselbe erfüllen. Und wenn man es gleich nicht sehen kan/so muß mans deßwegen nicht alsobald verleugnen. Denn es sind viel Dinge in der Welt/die wir nicht

6.7 Vacuum of Baron Zois

6.7.1 Introduction

A little less than 1.5 million inhabitants of the Illyrian provinces cut off the Habsburg monarchy from the sea with the continental barrier-blockade against England as well as for the French *trade* route to Turkey. "The natural" borders with the Kingdom of Italy were pulled down on the Soča (Isonzo) River, and the Illyrian provinces were directly subordinated to Paris, where Napoleon was preparing the abolition of feudalism of the just invented "Illyrians" which failed to succeed in all its might because of the premature Napoleonic Russian adventures.[1139]

The education in schools and beyond them is the sole salty benefit of every nation. During their four years of existence, Napoleonic Illyrian provinces brought about a dramatic change in the teaching and knowledge of the western part of the Slovene settlement, including Parisian novelties of vacuum technique. What kind of newness were the Slovenian nicknamed Illyrians getting into, and how many innovations in the field of vacuum technology survived the restoration?

6.7.2 The End of Jesuit Dominance in the Ljubljana Vacuum Survey

The first contacts of Slovenes with the French Revolutionary armies (1797, 1805, 1809) coincided with the cessation of the dominant influence of the Jesuits on Ljubljana's mathematically oriented education. In the years 1802 and 1803, the death and emigration of the former Jesuits the physicist Jernej (Bartolomej) Schaller and the mathematician Anton Gruber, the younger brother of the more famous Gabriel, terminated the Jesuitical lecturing in Ljubljana's Lyceum. They were the very last succession of once mighty Jesuitical pedagogical enterprise. On the one hand, the flag of knowledge was taken over by the Jesuit disciples, raised in the spirit of Bošković's physics: G. Gruber's pupil Jožef Marija Šemerl and Jurij Vega, G. Gruber's and Jožef von Maffei's private student baron Žiga Zois, Schaller and A. Gruber's pupil Janez Baptist Kersnik, A. Gruber's friend and opponent of Napoleon Jožef Kalasanc Baron Erberg, the Moravian immigrants professors Neumann and Hummel... Rarely prominent mathematically colored knowledge came out of the Jesuit's countertraditions in Scotus' opus. Among those eminent Scotus' followers was Kastul Weibl's (Caztallus Waibl, at the baptism Janez, * 28. 4. 1741 Novo mesto, 1756/57 OFM Novo mesto; † 25. 10. 1805) Franciscan pupil Valentin Vodnik, who designed Slovenian scientific terminology under the influence of Zois.

An essential novelty flooded in the Slovene and inner-Austrian natural sciences. After the violent demolition of the Protestant scientific bridge between the Tübingen University and Slovenian countries they were mainly infused with Jesuit ideas for over two centuries. Now they benefitted from the Napoleonic influx of non-native lay people who were well-versed in the modern discoveries of vacuum technique. Before the French occupation, such birds were quite rare in Carniola; among them, Balthasar Hacquet in Idrija and Ljubljana became a great local star. At the end of the Jesuit monopoly, after the termination of the lessons of the two former Jesuits, Schaller and A. Gruber, a relatively open competition of qualified Central European rivals for chairs on the Ljubljana Lyceum was enabled. In the first years after the end of Schaller and A. Gruber's lectures, there was no special demand; therefore, the mathematical and physical chair was filled in provisionally, and thus greatly lowered the level of instruction at the then already a century-old Ljubljana philosophical studies. At first, Napoleon's authority did not have a better choice over Kersnik, who became the leading teacher of natural science subjects. Kersnik had finished no other than the Ljubljana schools. Despite of the lack of education, and thus boasting a somewhat lower scientific level of instruction, Kersnik proved to be the most useful learning power, starting with precise French inventories of the cabinet of physics in 1811 with vacuum teaching aids included, through the geometric textbook (1830) to the benevolent fatherly teachings of physics by promoting Slovenian language responses of his benevolent students.

[1139] Šumrada, 2007, 76-78.

6.7.3 *Vacuum Technique of Illyrian Provinces at Central Schools in Ljubljana (1809-1813)*

In the first half of the nineteenth century, the Laplacian Parisian School developed an analysis and differential equations, mainly for physics and vacuum engineering, related to new steam engines. The lyceum of Ljubljana purchased even the Laplacian A philosophical essay on probabilities which has an internal red marbled paper cover with a hard-to-read pencil note about the allegedly original owner under his calculating exercises. On the last inner cover, there was a German advertising for sale of paper. The Ljubljana, Gorizian and Trieste mathematicians or physicists were fortunate enough to have come under the direct influence of the more advanced French colleagues during the Illyrian provinces, and thus, they could receive instructions about the numerous new discoveries. Schools in the Illyrian Provinces were organized according to the French revolutionary example of Écoles Centrales from the Jacobine era. The professors of the Illyrian provinces were much less impressed by the differently organized example of the École Polytechnique established in 1795 and the École Normale Superieure.

The Parisian high schools were publishing even their own scientific journals, from a birds-view looking like the lesser-known later secondary school Izvestje (Programm, Jahrsberichte) in the lands of the former Holy Roman Empire of German nationality. Some members of the Parisian Academy were willing to avoid longer delays in publishing in academic journals by disclosing their discoveries in the Journal de l'École Polytechnique or in the Journal of the Normale Supérieure. Unfortunately, the successful usable mathematics of the Laplacian school gathered around the "academy" d'Arcueil in the suburbs of Paris caused the lagging behind the Parisian mathematicians after Cauchy passed away, except for Cauchy's student Hermite and the half-brother of the French President of the Republic, Poincaré. The same thing happened to the Englishman, who were too overwhelmingly committed to Newton's genius, and stayed behind the development of the continental mathematics of Leibniz and Bernoulli. But these are later, pre-March stories.

Figure 6-218:Maximal-minimal thermometer and Papin's Pressure cooker with a pump at Koper Grammar school.

In the years 1809-1813, in Napoleon's Illyrian provinces, the higher studies of philosophy, medicine, and related sciences were fully upgraded only in Ljubljana. Even though the Gorizia folks had even slightly older philosophical studies, their schools did not get such promotions as their Ljubljana rival. Between 1785-1788 Joseph II abolished the philosophical studies in Ljubljana to free up the brain-drain of future Carniolan scholars to the larger Bohemian and Austrian provincial scientific centers. Napoleon developed higher studies in Ljubljana between 1810-1813, to prevent such an outflow of the local erudite. In the Habsburgian monarchy, Lycée of Ljubljana caused inconvenience, since at the time of the centralization of the state administration at the end of the 18th century, Emperor Joseph could not suppress enough all liberal free-flowing streams in remote schools when they were no longer guided by the Jesuit order after 1773. Napoleon, of course, had no longer problems like that.

Figure 6-219: Steam engine and barometer with siphon at Koper Grammar school.

The Frenchmen established university studies in the center of the Illyrian provinces of Ljubljana in accordance with the school policy of their empire. Interestingly, Napoleon's official did not easily found professors of mathematics and chemistry among the domestic lecturers. It seems that in the natural science fields focusing the study of the vacuum technologies there was the most powerful outflow of educators into the more scientifically developed Habsburg schools, although from there, namely from the golden Prague, Napoleonic Ljubljana received excellent mathematician Gunz.

The three years of the existence of high schools in Ljubljana as the central educational institutions of the Illyrian Provinces certainly encouraged the later demands of the University of Ljubljana. After the March Revolution, the dream of the domestic university became the common message of educators from lands inhabited by Slovenes. In a short interval of time of the Illyrian provinces, with the probable exception of Gunz or Ž. Zois Ljubljana residents did not attribute significant scientific achievements, since education in the Illyrian provinces was constantly in the middle of financial turmoil.

In 1810/11, in two-year and three-year (Ljubljana) gymnasiums of the Illyrian provinces nobody taught physics or science. Also, on colleges between 1811-1813 and on a five-year Lyceum in Ljubljana there was no lesson in science. In the middle school stage, they taught physics inside the natural sciences only in 1810/11 at the lyceums of Trieste (astronomy), Koper and Gorizia.

In 1810/11 in the part of the Illyrian provinces inhabited by Slovenes, only Kersnik lectured on physics in the first years of all five faculties of the Central School in Ljubljana. Kersnik followed Neumann's textbook published in the Latin language; Neumann was Kersnik's teacher and predecessor in the same department in Ljubljana, so the choice of his textbook was quite inevitable. Twenty-seven years old Neumann from Moravia became a professor of the Ljubljana grammar school on 21 July 1801 and stayed there until his departure from Ljubljana. In addition to his classes in grammar school, on February 16, 1802 he became a teacher for Greek language. On 3 May 1803 he replaced the diseased Schaller and became the first full professor of physics who was never Jesuit in Ljubljana's Lyceum on October 31, 1803. On 12 September 1806, Neumann together with the director of the Ljubljana Philosophical Studies, F. Wilde, signed a certificate of the Greek Philology exam for the student Jurij Paušek.

In autumn 1806, Neumann left Ljubljana for the University of Graz, where he taught astronomy at Joanneum since 1812. Unlike Ambschell before him, he first published a Latin language physics textbook in Graz between 1808 and 1812. His textbook was translated into German a decade later. He published the translation in Graz and dedicated it to the imperial personal physician Andreas Josef baron Stifft (1760-Röschitz in Lower Austria-1836 Vienna). He dedicated his song to his director at the Viennese Polytechnic, Prechtl.[1140]

The first part of Neumann's German translation comprised 560 pages in 522 chapters, and at the end, he added twelve tables of copperplates with 270 small images. The longer second part of the textbook has 722 pages. On pages 723-783, he put out a table of contents for both books, although each of them already had tables of contents at their beginning. He has published fifteen copper plates, with a total of 372 images, on five pages including the list of errors. It was almost genuine for the eyes of diligent students. On the penultimate figure 371, six different shapes of snowflakes were drawn in the spirit of the then emerging mineralogy, which Gruber and Hacquet also helped to develop. The Latin NUK edition of Neumann's textbook is lost today, and the German translation was once Zois's with a reinforced leather back of cardboard covers, triangular leather edges of covers and red marble inner covers.

Neumann has drawn a comet (tab III), Tycho's system (tab IV, fig 47), a very fortunate illustration of a vacuum pump,[1141] a Leyden jar as an accumulator of electricity (tab VIII, fig 171), capillary (tab IX, X), and crystalline forms (tab XI, XII). The sketches in the second book were dedicated to sound (tab I, II), a telescope with a micrometer to measure the rotation of the polarization plane (tab III), the steam engine (tab V), the eye (tab VI), the geometrical optics (tab VII), the bipolar crystal tab IX), refraction and eye (tab X), microscope (tab XI), Leyden jar (tab XII), vacuum pumps, rainbows and snowflakes. Among the Latin language textbooks, at the beginning of the second volume, he recommended Newton's Principles, 'sGravesande, Ch. Wolff, Musschenbroek's Institutiones (1748) or Introductio ad philosophiam (1762),[1142] but not Bošković, although Neumann described Bošković's dynamic theory of point-contact bodies as the last word of the dynamics and therefore most relevant.[1143]

Among the new German textbooks printed after 1790, Neumann praised Imhoff's manual, which was also used by the Franciscans of Novo Mesto (New City). Among the new Latin textbooks, Neumann also boasted his own, Ambschell and Döttler's work.[1144] Among foreign editions, Neumann also recommended Biot, Cavallo, Th. Young, Playfair and Giuseppe Saverio Poli whom Zois also read. Among the encyclopaedias Neumann liked to examine Gehler's work, but among the journals and newsletters of scientific societies Neumann acknowledged almost everything. Among physicists he praised Fischer and Gilbert,[1145] and among the specialized works Neumann favoured Priestley's optics and electricity, Pfaff, Bohenberger and Brandes's book issued in 1820. Neumann was interested in Beccaria's experiments with phosphorescence of animals and plants,[1146] as well as Bologna stone and John Canton's phosphorus.[1147] He presented Newton's emanation theory of light and the opposite Euler vibrational system, as well as the dynamic variants of the vibration system of Huygens and Descartes;[1148] but Neumann did not say which version he was supporting. He was interested in a photometer[1149] besides the Newtonian colors on a prism,[1150] but he also pushed forward Goethe's criticism of mainstream Newtonian optics.[1151]

In 1842 Neumann reprinted the first part of his textbook. In 1815 Neumann left Graz and from 1816 until retirement in 1844 he was a physicist and secretary of the Polytechnic in Vienna. Today, near the Polytechnic, Neumann's memorial plaque is built under the bell tower next to the church. In 1819, in the first yearly volume of the Polytechnic Institute News, Neumann published a paper about Abraham-Louis Breguet's bimetallic strip thermometer.[1152] Breguet was a watchmaker in

Paris, a member of the Parisian Academy and of a length bureau. He left the position to his nephew who was also a famous watchman, while in his free time he measured the speed of light and sound in various substances.

The older Breguet did not only learn how to make clocks; two years before Neumann's discussion he published research on temperature measurements by observing the stretching of the metal. Breguet used a tension spring that extended during heating. He placed the needle on the bottom for reading the temperature, but of course he set the scale empirically. He collaborated with his forty years younger fellow watchmaker-watch-dealer Jean Charles Athanase Peltier (1785 Ham-1845 Paris) who researched the thermoelectric currents for Seebeck’s thermocouple. In the late 19th century Breguet's thermometer was used in schools. In 1900, nearly a century after Neumann's description, James W. Queen & Co. from Philadelphia sold Breguet thermometers for $ 25.

Besides Breguet's merits, Neumann also attributed the invention of metal thermometers to Samuel Christian Hollmann (* 3. 10. 1696 Stettin; † 4. 9. 1787 Göttingen), a full-time professor of philosophy at the University of Göttingen and director of a local scientific society. Hollmann was, of course, mainly concerned with barometers, but he also liked thermometers.

After moving to Graz, Neumann published a textbook Compendia physica institute in three parts in 1808-1812. Neumann's student Kersnik acquired Neumann's Graz textbook in Ljubljana immediately after printout. Under number 17, it was recorded in the Supplementum (additions) of the Wilde’s list of the Lyceum Library of Ljubljana in 1789-1809.

Between 1811-1813, the Academy of Ljubljana had a special one-year philosophical faculty. There Kersnik lectured on physics in French language to the seventy-two students, and next year to seventy students. In 1812/13, some students of philosophy also passed exams from cosmography which combined some astronomical approaches.

6.7.4 The Jew Gunz - Ljubljana Brightest Scientific Star

After Jenko's resignation and short Kersnik's replacement the new French school authorities entrusted the Chair of Mathematics to Jenko's friend, Samuel Gunz (Leopold Gientz, Guentz, * 1782/85 Prague). Because of the war shortages, the perspectives of the Ljubljana newly established educational chairs did not really flourish before the Napoleonic occupation, which suddenly woke Ljubljana from a centuries-old sleep as the seat of the Illyrian Provinces and a center of education with its university. The educated professors, such as Zelli and Gunz, were attracted by the French scholarly novelty into the sleeping Ljubljana. Gunz was the professor of basic (elementary) and applied mathematics from the autumn of 1810 until the year 1819.[1153] Occasionally, Gunz’s assistant was employed to teach the basics mathematics. Gunz arrived in Ljubljana from the mathematical department in Gorizia; there he also left his mark, which was later upgraded by the slightly younger Močnik and A. Cauchy on mathematical basis. Between 1812-1813, the mayor of Gorizia was Francis Janez Neri de Maffei (* 23 November 1738 Vipava; † 8 January 1826 Duomo in Gorizia), brother of the former Ljubljana professor of mathematics and Zois's private teacher, Joseph Jakob Liberatus Maffei de Glattfort.

Charles Nodier twice mentioned Gunz when listing well-established Illyrian scientists. For the first time, he wrote his surname as Günz on February 1, 1815 in an article for the Journal des Débats, and secondly as Gienz in the article entitled Laybach, published in La Quotidienne on 15 January 1821; Gunz's membership in the Carniolan Agricultural Society, the interest in the Slovene language with its grammar included, the enthusiasm of poetry and natural science were highlighted in both publications. Nodier praised Gunz as a lexicographer and a grammar expert without mentioning his professorship of mathematics, which seemed to be strange, as if Nodier was narrating about another guy. In his articles, Nodier used Hacquet's ethnographic work in Breton's French translation, and among the meritorious "Illyrian" scientists, Nodier listed Bošković,

[1153] ZAL, SI_LJU 184, Accessory fond 1., Technical unit (Tehniška enota) 53.

Bošković's friend Benedikt Stay, Raymond Cunich, Brno (Bernardo) Zamagna who published the Latin verses about the Jesuit vacuum balloons of Lana Terzi from Brescia, and other Dubrovnik natives with Dalmatians included.[1154]

Samuel Gunz was the son of Rabbi Simon Gunz, a teacher of mathematics, measuring of bodies, commercial computing and German reading in the Israelite high school in Prague (Israelitische Deutsche Hauptschule Prag, Hauptschule der prager Israelitengemeinde) which worked in 1782-1850. Simon Gunz taught there at Jüdisch-deutshen Schulanstalt in Prague in 1782-1817, while his wife Anna taught girls the female domestic works at the same school in 1782-1813.[1155]

Simon Gunz published textbook *Theoretisch-praktisches Rechenbuch für Lehrende und Lernende* dedicated to the count Henry Frances Rottenhann in Prague in 1802. The count Henry Frances Rottenhan (1738-1809) was the highest Prague burgrave who served as administrative lawyer, president of the supreme court of justice and court commissioner for legislation in Bohemia and Austria. The textbook was reprinted six times in Prague in 1808-1832. In 1809 and 1821, Simon Gunz published the updated instruction of Johan Christian Nelkenbrecher († 1760) for the exchanges of different European money, weights and measures into the Viennese units. So, Samuel Gunz learned the secrets of numbers already in his native Prague house. He passed his (applied) mathematical exam including the final mixed queries about vacuum pump (no. 236) and barometer (no. 237) published on page 50 among 247 exam questions in a public examination. He was then a graduate student of second year of philosophy in the class of Stanislas Vydra (Wydra, 1741-1804) in Prague university on July 27, 1802. The situation in Carniola was known to the Prague native Gunz by the narration of Tobias Gruber, the brother of the professors of Gabrijel and Anton of Ljubljana, who was close to Gunz during their Prague mathematical and physical research.

In 1809/10 Samuel Gunz started teaching at the Ljubljana Academy for nine students of mathematics in the second year of the French Central Schools in Ljubljana. The Ljubljana French college had about 300 students in its first year of existence. The freshmen were on average eighteen to nineteen years old, which was around a year more than elsewhere in Europe. The reason may not only be the lack of knowledge of Carniolan boys, but especially the disorder of the continuing schools during those difficult hardest war times.

According to the rulebook, signed on 1 August 1810 by the former candidate for the Ljubljana professor of mathematics and then the director of the lyceum in Zadar public health inspector Rafael Zelli, the future doctors, surgeons, pharmacists, theologians and lawyers in Ljubljana did not study mathematics. The engineers and architects attended mathematical lectures in the second, third and during their last fourth year of studies.

In 1810/11, Gunz taught theoretical mathematics and practical geometry to five students of the first year and to eight second year students of the Faculty of engineers and architects. He lectured in Latin language. In 1811/12, mathematics was taught in the third and fourth class, where the teaching was taken over by Kalister who used the previous Habsburg textbook. In the fifth year, Gunz interpreted optional mathematics lectures to only five out of seventy students; he used his own notes, most likely those he published several years later in his book. Thus, Kalister and Gunz shared mathematical curricula according to the ancient practices; Kalister explained introductory chapters, and Gunz taught higher mathematics, which was no longer limited to astronomy.

In 1811/12, Gunz instructed his students as the future engineers and architects about the secrets of transcendental and "special" mathematics. He trained nine (sic!) students of mathematics from last year's second class about trigonometry. He taught them the algebra in geometry, differential and integral calculus. Gunz even assessed his students' behavior, which, of course, is a bit unusual for a modern university. However, at those

[1154] Dahan, 2006, 267, 272, 274-275; Maixner, 1960, 26, 37, 65, 66, 103, 105. On 13th December 1779 Zois even helped the Viennese acquisitions of books for his former teacher Maffei (Svoljšak, Vidmar, 2019, 27).

[1155] Britta L. Behm, Uta Lohmann, Ingrid Lohmann. 2002. *Jüdische Erziehung und aufklärerische Schulreform*. Münster/New York/München/Berlin: Waxmann, p 247; Královská česká společnost nauk, *Kaiserlich Königlicher Schematismus für das Königreich Böhmen auf das Jahr…*, Prague: Jan Nepomuk Ferdinand Schönfeld, 1795: 206, 1813: 53.

different times all exemplary behaviours were perhaps the result of politically "correct" beliefs. Gunz's students would be able to graduate next year, but Gunz then ceased lecturing. On 13 July 1813 he had mathematics exams, but they were not mandatory. Gunz's students wanted to continue their studies at the Polytechnic in Paris; unfortunately, Napoleonic battles in the burning Moscow almost buried their dreams about the Elysian Fields. The new / old Habsburgian rulers preferred Viennese educations of Guns' students, although they had to "leave the belly outside" because of the high prices in the capital on the banks of the Danube. Among Gunz's students, Čop, Jovan Vesel Koseski and France Prešeren[1156] proved themselves. Gunz as a benevolent teacher later assisted with the services and with his Viennese recommendations in favor of both Čop and Koseski. Gunz recommended Koseski to the Viennese professor of Kantian theoretical and practical philosophy Leopold Rembold in 1818. Among Rembold's student was also the baron magnate Simon Georg Sina (1810-1876). If Gunz really liked poetry so much as Nodier claimed, Gunz might have been also nice teacher to the future leading poet France Prešeren as Gunz also attended Franc Metelko's Slavistics lectures in Ljubljana Lyceum as a member of Carniolan agricultural society.

In 1815 Gunz published a book on parallel movements used in the theories of Swiss Euler's student Louise Bertrand (1731–1812)[1157] and Johannes Schulz (* 1739) with the mention of Schenkel. At Calvin Academy in Geneva Bertrand arranged Euler's discoveries for trigonometry; with his many books, he influenced Lacroix, and in paragraphs of geometry, he also described the history of geometry. After Napoleon's first downfall in December 1814, Gunz dedicated his work of sixty-two pages with two sketches to his "dear friend" Gunz's Ljubljana's predecessor Jenko, then a professor of mathematics and technology at Joanneum in Graz. The introduction to the book was signed in December 1814 as soon as Gunz accepted the Catholic faith. In those times Napoleon was residing on Elba after 4 May 1814, but in Europe the weapons would roam around again during Napoleon's 100 days between March 20, 1815 and Waterloo of 18. 6. 1815. Gunz divided his book into pure mathematics with the basics of parallel lines theory[1158] and technical mathematics with the description of city bells in the towers.[1159] Gunz painted two pages full of pictures: the first with parallels, the second with sawed broken lines.

Gunz urgently recalled the problems of the theory of parallels,[1160] which really led to the non-Euclidean geometry of the Russian Lobachevsky and the Magyar Bolyai few years later. In the second addition he described Legendre's theory,[1161] in the third Bertrand's derivation of the Legendre's *Éléments de Géométrie* (1810)[1162] and in the fourth Schulz theory;[1163] Schulz also published the foundations of an infinitesimal calculus. In the end, Gunz added J.P. Neumann's description of the sundials (Gnomons) in the towers depicting the artworks of Joseph Geist (1770 Vienna-1824 Graz) and astronomical pendulum clocks. As the leading specialist for pendulum watches, Joseph Geist and his relatives established the first Habsburgian fabric of clocks in 1819.

The first non-Jesuit professor of physics in Ljubljana, Neumann, was a professor of physics at Graz at the time, and Gunz was obviously in close contact with him as well as with Jenko. Neumann was indeed co-author of Gunz's book on parallels, as Neumann independently signed it at the end of his paper on pages 59-66.

In view of his study of the recently issued Parisian researches, Gunz's book was very modern. He finished it with two tables; in each he drew six simple geometric sketches that he referred to in the text. Gunz's book came to the Lyceum library with the purchase of Zois' Book Treasures along with Neumann's Latin textbook,[1164] which shows the obvious connection between those Ljubljana's peers.

In Ljubljana, Gunz lectured in Latin language. He used the textbooks by Sylvester François Lacroix (* 1765; † 1843) on an infinitesimal calculus;

[1156] Dahan, 2006, 271.
[1157] Mistakenly noted by the name of count Henri Gatien Bertrand (1773-1844), the general governor of Illyrian provinces from April 1811 up to 1812 (Dahan, 2006, 272).

[1158] Gunz, 1815, 1-58.
[1159] Gunz, 1815, 59-60.

therefore, for the needs of his lesson in Ljubljana, Gunz acquired Lacroix's textbook of mathematics. Both books are not noted in F. Wilde's catalogue, nor in the Zois' list of books; they obviously got them later in Ljubljana Lyceum. The first edition of the Differential and Integral Calculus of Lacroix was printed in 1797 in two parts. It became a textbook of École Politechnique, used for generations. The second edition was printed in 1806 when the English translation was also published. From 1788 to 1793 Lacroix lectured at the artillery school in Besançon in eastern France, where he befriended Nodier's mentor Giordo de Chantrans. Lacroix introduced the term "analytical geometry." At the times of the Illyrian provinces he lectured at Sorbonne. In 1799 he became a member of the Institute; he achieved his best in probability theory and mathematical analysis; and above all he proved himself with many successful textbooks.

After Napoleon's defeat, the expatriate Jew Gunz expected problems in white Ljubljana. To help him, the mathematics professor A. Wolf (Volf), was also employed at the restored Lyceum instead of Kalister. On 11 September 1814, Gunz was baptized as Leopold in the Ljubljana cathedral, "Sentklavž". Without the Christian faith, he felt a little marginalized in the high society of Carniola, and therefore the transition to the Catholic Church seemed to him to be very promising, but he also had to lead his own religious inclination. At last in those times after restoration Gunz openly opposed the so-called enlightenment and nursed some ties with the Viennese university professors of theology. He converted just few weeks before he signed the dedication into his new book to be published by Miller in Graz which probably gained the prestige with Gunz's conversion. He planned the transition accurately enough as an important social event. The ceremony was led by V. Vodnik's friend the retired vicar of Ljubljana cathedral Jurij Miklavčič (Miklautschitsch, 1756 Zali log in Upper Carniola-1829 Ljubljana) with the general interest of the faithful from close and far. Gunz's godfathers were a professor of church law and history of the church in Ljubljana Jurij (Georg) Dolinar (* April 19, 1764 Vovče in Poljane valley; † 21. 10. 1858 Ljubljana) and councilor of the regional court Anton Gogala (* about 1789 Lesce by Bled; 1835 von Leesthal; † 9. 10. 1841 Trieste). The District Commissioner Hensberg in Styria, Gogala, volunteered to fight against the French as a captain of the Home Guards (Brambovci). Nevertheless, he became the judge of the tribunal of the first instance of the Illyrian Provinces. Gogala's older brother, Jósef Balant (Walland, * 28. 1. 1763 Nova vas near Radovljica; 8. 3. 1818 Gorizia Bishop; 3. 8. 1830 Gorizia Archbishop; † 11. 5. 1834), served the French as director of the Academy in Ljubljana; he was one of the most influential ecclesiastical people and certainly an important guy on the balance of Gunz's conversion. The Graz student Dolinar was a student of physics in the class of a former professor of Ljubljana Leopold Biwald. Between 1810 and 1813 in Ljubljana the professor Dolinar taught Roman law and Code Napoléon.[1165]

The baptized Gunz was a provisional professor of mathematics in the renewed Ljubljana Lyceum in 1814 and 1815, after which he took over the chair as a full professor. In 1819, he left the white Ljubljana and became a professor of higher mathematics on a Lyceum (Akademische Gymnasium) in Linz where Boltzmann studied in 1855-1863. In 1824, the professor of applied mathematics, physics and Natural History in Lyceum of Linz was Adam Mathias Chmel (1770 Teschen-1832 Linz) who taught there from 1803, and the professor of pure mathematics and Greek language was the Cistercian Johan Baptist Schober (1783 Oberweißenbach-1850 castle Mühldorf, Feldkirchen a.d. Donau) who taught mathematics there from 1807. Therefore, Gunz might have taught in Linz just as a replacement for Schober who toured Naples and Switzerland in 1818, but Gunz was never noted in official registers or the Lyceum of Linz nor anywhere else in Habsburgian monarchy after the school year 1818/19. Leopold Gunz's affairs in Linz might be misinterpretations in SBL, as he ceased to be a member of Carniolan Agricultural society in 1819. He might have visited his elderly father in Prague if his father the rabbi was not to uncomfortable with his recently converted son. Most probably, Leopold Gunz left Habsburgian monarchy, or he died. The chairs for mathematics and physics were vacant in Linz Lyceum in 1830-1833.[1166] Gunz's eventual

[1165] Glonar, 1925, 142.
[1166] Benedict Pillwein, *Beschreibung der Provinzial-Hauptstadt Linz und ihrer nächsten Umgebung, mit der ältesten Geschichte und mit einem Umrisse des Erzherzogthums Oesterreich ob der Enns als Einleitung; von Benedikt Pillwein, k. k. position in Linz was not higher than in Ljubljana, although the city itself was more important. Gunz's departure had to be sufficiently unexpected for the school authorities in Ljubljana, as Gunz was only temporarily replaced by Kersnik for a long time.

6.7.5 *Kersnik and Zois's Model of Vacuum Blast-furnace*

Janez Krstnik Kersnik (* March 26, 1783, Moste pri Žirovnici in Upper Carniola (Gorenjska); † 24 June 1850 Ljubljana) first lectured on physics at the fully established University of Ljubljana's higher studies. The wealthy father brought him up with the income of his farm, mill and sawmill. Janez Kersnik's grandson was the writer Janko Kersnik.

Figure 6-220: Kersnik portrait (Kersnik's great-granddaughter's gift)

Kersnik had a good command of French language, which at that time was a great advantage for a professor in the Illyrian Provinces. In 1809/10, he lectured in French language at Central schools in Ljubljana, and in 1811 he listed experimental devices in the cabinet of chemistry and physics of the Central schools in the French language with some minor spelling mistakes. The list shows that Kersnik really had something to show to his students, as he did not miss the latest teaching aids. As the first device in the chemical cabinet, he listed a vertical pneumatic device or a vacuum pump, and the second one was Ž. Zois invention of blast furnace and associated movable supports. It seems that Zois used the recent the development of a vacuum steam engine to design a model for Kersnik's demonstrations to technically talented students in his Ljubljana School. Kersnik had two other bellows with a board and lamps, two thermometers with metallic measuring scale, a balance with weights made of brass, a smaller and larger scales, a battery with a voltaic cell, two aerometers, a large bellow with a long copper tube, a copper pneumatic tub (for vacuum experiments) and a silver lantern with all needed supports. In the Hydrostatics Department, the conscientious Kersnik kept two tubes connected to the third in communicating vessels, a hollow cylinder of glass and brass. Together with them, he placed a partially framed truncated cone, an elongated gilded vase, a Viennese volumetric measure made of brass, a double fountain, a cubic inch as a hollow measure, a collection of all simple hydrostatic devices, several glass bells. For vacuum experiments, he collected an opened glassy hollow ball, a Magdeburg hemisphere for proof of the vacuum, a hollow copper opening, three very small valves, three medium sized cylinders for the research of vacuum with a pump, Heron's water pump with a rotary jet, a pneumatic device (a vacuum pump resembling the one listed above), a barometer, an intermittent fountain consisting of a cylindric glass tube with its upper end pear shaped which penetrates to its full length to the bottom of a tray, a double fountain and a Cartesian diver containing a weight more dense than water and an air bubble less dense than water. When the container is squeezed, the internal air pressure increases, and the size of the bubble decreases. As a result, the density of the diver changes from being less dense than water to being denser than water and the diver sinks. It was acquired already by B.F. Erberg for the Jesuits of Ljubljana in 1755.

Kersnik greatly improved his collection in 1811 when he acquired the portable Volta's zinc-gold battery, the optic observation of the floating feather, the hygrometer with a thermometer and a pneumatic lighter which was probably a Voltaic pistol. Early in the same year, the general governor of the Illyrian Provinces, the Duke of Dubrovnik Marshal Auguste-Frédéric-Louis Viesse de Marmont (* 1774; † 1852) donated his extensive laboratory to Kersnik's cabinet of the Ljubljana Central Schools. The gift included a detailed analytical balance and Volta's battery at a voltage of 100 V (perhaps the one which Kersnik listed), a

154, 1820: 155, 1821: 164, 1827: 159, 1830: 152, 1832: 153, 1833: 251, 1834: 153

galvanic battery with hundreds of elements of copper zinc, a distillation apparatus, a gasometer, an audiometer, an annealing furnace, high temperature gas heaters, fourteen retorts, twelve bottles of Irish chemist, alchemist and mineralogist Peter Woulfe FRS (1727–1803) as an apparatus for purifying or dissolving gases, which employed a bottle with two or three necks designed ca. 1767, nineteen funnels, two muffle furnaces (oven, retort furnace, fourteen containers, thermometers, aerometers, glass, metal and porcelain pipes, several hundred laboratory flasks, two hundred glasses, porcelain cooking pots, iron and wooden stands, tweezers and spoons.[1167] Marmont obviously learned a lot from his private chemistry teacher, Zelli; Marmont certainly liked to get some buzz at home. On 16 November 1809, Marmont arrived in Ljubljana Bishop's house as General Governor of the Illyrian Province, and he returned to Paris at the beginning of 1811.[1168]

Figure 6-221: Present of Kersnik's students for his name day (Janez Šumrada's gift)

6.7.6 *Science Outside the Center of the Illyrian Provinces in Novo mesto, Gorizia, Trieste, Koper, Zadar*

Ljubljana was never so important as during its capital role Illyrian provinces. The other cities of Illyrian provinces also profited from those sudden changes, despite of heavy military burdens. The priest and their religious orders suffered a lot, but the lay erudite got their chance. Weibl's student, the Franciscan Valentin Vodnik, indebted Slovenians more than any other St. Francis's heir. Among other scientific works, he accomplished some telescopic observations with Zois's support. The Napoleonic government changes at Zois' science and Kersnik's education enabled French revolutionary novelties. They upgraded the last traces of the Jesuit's centennial education of physics and mathematics at Ljubljana higher philosophical studies with Gunz, Kersnik, and their supervisor, Zelli. The relations between the leading literati of those days Ljubljana included Nodier, Marmont, Knauer, Vodnik, and Ž. Zois. The chief Napoleonic antagonists were Rijeka based Brits consul John Leard (Laird, 1760-8. 10. 1843) and general Laval Nugent.

The French invaders organized the studies in the Illyrian Provinces as they did in the Parisian revolutionary Jacobin *Écoles Centrales*. The Frenchmen established the Illyrian Provinces metropolitan Ljubljana University to prevent "Illyrian" brain drain to the Habsburg Empire. Napoleon's administrators had the hard time to get the useful professors for chemistry and related subjects because the domestic experts were considered insufficient. The other Illyrian Province schools in Gorizia (Gorica), Trieste, Koper, Rijeka, and Zadar were no longer mastered by religious orders under the Napoleon's rule. The destiny of Napoleon's scientific ancestry at Slovenian lands provides the surprising conclusion that the Restoration brought almost no changes, because the Ljubljana professors of sciences kept their chairs also under Metternich's regime to support the poetical thoughts of Gunz' student, Jovan Vesel Koseski: »The changes are only damages, just few of them remains«.

Zois' circle is the key for understanding of the Illyrian provinces literati of Napoleon's era. Zois' collection of minerals was comparable to with the Kersnik's one at Lyceum. Vodnik's collaboration with Zois was reflected at Zois' literature on numismatics, and even in his Serbian and other mathematical textbooks for the beginners, which helped Zois and Vodnik on their invention of the Slovene mathematical terms. Zois published one of the most important early scientific description of Proteus. He used his home library as the source for his experiments and observations, and he also studied many modern scientific journals he ordered around Europe. Baron Žiga Zois learned his mathematical sciences during his private lessons

with Gabrijel Gruber and Gruber's assistant Maffei in Ljubljana. Two centuries ago Zois became the most important literati in Ljubljana.

6.7.7 *Capuchins and Franciscans in French Ljubljana and Gorizia*

Napoleon's era was not written on the skin of Franciscans. In 1809, the French disbanded the Capuchin monastery of Ljubljana by the resentment of Marmont's wife, who became angry during the Capuchin's fiery sermon. His not quite crystal-clear handkerchief flew into the bosomed beautiful breasts of Mrs. Marmont. So, she outrageously exclaimed in the middle of the land of savages, so far from the Parisian paintings. In 1817 the monastery was demolished along with the church. However, reports of the further fate of the incriminated handkerchief, despite careful investigations, do not say anything clear for the time being.

Figure 6-222: Lalande's title page (Lalande, 1769;).

About two hundred books from the Ljubljana Capuchin Library went to the Capuchin church of Škofja Loka. Valentin Redeschini De Haidovio Radeschini, * 21. 7. 1746 Ajdovščina, OFMCap 1765; † 4. 2. 1810 Gorizia), the most important Slovenian capuchin of Napoleon's era, returned came to the "Illyrian" Gorizia in his last days; he described the vacuum on the model of Bošković.

Notwithstanding the above-mentioned handkerchief, on 6 January 1811, the French army of Marshal Marmont expelled the Gorizia Franciscans from the St. Anton of Padua's Monastery to nearby Kostanjevica. Since 1821, they have been developing a gymnasium with a Philosophical school for the teaching of theology, mathematics, physics, philosophy, history and Latin language, which also worked successfully during Cauchy's two-year exploration of optics, ether and vacuum in Gorizia. They started modestly, with two teachers and two students. The first lecturer taught religion, mathematics and physics; the Franciscan certificates were publicly valid and allowed the graduates to teach at gymnasiums, including two of them which were led by the Franciscans in Novo mesto and Kostanjevica. The Kostanjevica Gymnasium was later transferred to Kamnik.

6.7.8 *Zois's Vacuum Science in his Networks Captured by the Armed French Gentleman*

Zois (* 23. 1. 1747 Trieste; † 10. 11. 1819 Ljubljana) was a graduate student at the Seminario-Collegio for laymen or sons of the newly ennobled families who were enroled at the spiritual seminary Reggio Emilia (October 1761-1765). The institute was founded on 1 November 1750 and abolished in 1790, but later operated under other names.[1169] In 1763/64 and 1764/65, Žiga studied computing, sciences, architecture, drawing, and basic experimental vacuum techniques. Reggio Emilia had a Jesuit school established in 1618, and since 1752 there has been a university[1170] where physics and mathematics was taught by Lazzaro Spallanzani (* 12. 1. 1729 Scandiano by Modena; † 11. 2. 1799 Pavia), after his cousin Laura Bassi (* 1711; † 1782) turned him into natural science fan during his studies at the University of Bologna. Spallanzani opposed the spontaneous generation by his experimentally overheated microorganisms; he corresponded with the Swiss biologist Charles Bonnet, whose book Zois had. At Zois College, Spallanzani taught Greek and French language. Žiga's brothers learned those languages.[1171] Žiga did not learn Greek language, but he may have studied French

[1169] Kacin, 2001, 50, 62.
[1170] Kacin, 2001, 45.
[1171] Kacin, 2001, 47, 62, 78.

language in Spallanzani's class, although there is no archival data about those facts. In 1769, Spallanzani took over the chair in Pavia,[1172] and in 1785 he collected natural curious discoveries along the Mediterranean and even in Turkey. Spallanzani has anonymously put an artefact from chicken tissue to semi-blind Scopoli, as if it were the species of still undiscovered nematodes (roundworms); the elderly Scopoli did not notice the hoax and urgently published his new "discovery" in his book. In the year of Scopoli's death, Spallanzani published a letter to Scopoli with the criticism of Volta under the pseudonym Francesco Lombardini. Later, Spallanzani quickly decided to support Galvani's theory of animal electricity in his dispute with Volta,[1173] which probably means that he did not support the French revolutionaries whom Galvani or Zois also disliked. In fact, Napoleonic victories promoted Voltaic ideas.

Figure 6-223: Lalande's chapter about his visit to Piran native Tartini, also read by Zois in his collection (Lalande, 1769, 8: 292).

Žiga Zois did not have Spallanzani's works. Žiga Zois developed his naturalistic mentality with his uncle's mother the physician Janez Krstnik Pollini[1174] in Ljubljana. Zois advocated a Neptunistic theory against JE Fichtel and other volcanists also with evidence from Triglav mountain range provided by Vodnik and F. Hohenwarth after their Triglav expeditions in August and September 1795. During that time Vodnik worked as the parish manager in the Bohinj areas of Koprivnik, observed the geological strata at the Triglav peaks through the binoculars and described his feelings in the Vršič poem in August 1795. In September he accompanied Zois miners to gather fossilized sediments below the very top of Triglav.[1175] At his home, Zois hosted naturalists Hladnik, Hacquet and Šemerl.[1176]

Zois postponed his common youngster travels, probably due to his father's needs for help. He journeyed only relatively late from early 1779 until the spring of 1780. He visited many places including Switzerland, France and the Walloon part of the Habsburg Netherlands in near the borders of modern Belgium, where the goodwill memory of the deceased empowered minister Ljubljana Count Kobencl still used to be strong. Zois's return was forced by his gout which shew him its teeth in eternal Rome. In 1782, Zois had been unsuccessfully treated for several weeks at the city of Spa, the Belgian spa in the Province of Liège.[1177] Thus, the baron of Ljubljana was very impressed with the enthusiasm of French natural sciences and the knowledge of the French language before the evil gout thrilled away his joy from everything outside the house. Zois purchased most of his French mathematics, physics and chemistry printed in the first two decades of the revolutionary Paris. Among other things, he also acquired the works of determinedly free-minded naturalists, such as Lalande and mathematician De la Metrie, the namesake of a more notorious older materialistic philosopher.

6.7.9 *Zois's Library*

Zois' Library with 4000 notebooks was available to a wider circle of Slovenian enlightened writers; the specimens of former Zois' books in NUK or NMLJ are identified by the characteristic marble inner covers with the prevailing red color, brown leather binding and the golden name of the author above the title and flowers on the spine. Those books do not have Zois' proprietary entries, but their shape speaks for itself. Zois has probably designed them for resale at the time of purchase. Names of Zois's librarians are not known. The

sales catalog was compiled by Henrik Viljem Korn. Henrik completed his list of 4109 volumes on 4 August 1821. After the end of the religious ban, Korn settled as one of the first Protestants in Ljubljana, and he became an independent bookseller in Ljubljana in 1788. On December 31, 1790 and February 7, 1793 Korn wrote to Zois from Vienna. The Ljubljana Lyceum library did not buy all Zois' books, since some of them the Lyceum already had, while Žiga Zois' nephew Karl Zois offered mainly technical and natural works from his inherited estate. On 9 April 1824, the government paid 7000 guldens, and the books were transferred to Lyceum between June 24, 1824 and August 1, 1824.[1178]

Lavoisier's novelties influenced Zois through the work of Madame Elisabeth Fulhame, a wife of Dr. Thomas Fulhame. In the High English society, Mrs. Fulhame communicated with the most important physical-chemists of her era, among them with Joseph Priestley. Her reflections on Phlogiston discussion with the traces of later catalytic theory would excite Lavoisier, but he lost his head few months before Elisabeth Fulhame's publication which would surely delight him as the way of the subsequent discovery of catalysis. The translator Augustin Gottfried Ludwig Lentin (1764 Dannenberg in Lower Saxony-1823 Sülbeck near Eimbeck) apologized as he somewhat changed the title because he did not want to mention old-fashioned phlogiston anymore in November 1797.[1179] Fulhame signed her own introduction in November 1794, but in October 1793 the chemical research completely changed its course[1180] after Lavoisier's revolution in the nomenclature, weighting, and research approach to the chemistry and fire. Fulhame divided her research on the formation of metals,[1181] reduction of metals with phosphorus, hydrogen,[1182] and light,[1183] and finally the oxidation of metals[1184] mostly in hydrogenous media.[1185]

Zois bought at least three Berthollet's books and used marbled red-green paper for their inner cover. Among them Zois acquired Bertholt's work printed in 1803, although there is no note about it in Kopitar's Schober's, Zupan's catalogues or in Kalister-Korn's sales catalogue. The book was bind, as usual, to Zois' brown leather with marbled red-green inner covers. Berthollet began by explaining the cohesion force without mentioning Bošković,[1186] and he published a special chapter about the caloric.[1187] Berthollet devoted his last sixth section of the first volume to the operation of the atmosphere,[1188] and then in the second volume Berthollet explained the chemical activity of the various substances. Berthollet dedicated his last fifth section of the second volume to plants and animals, therefore to the botany and zoology. Zois' copy of that book was one of the inexpensive Parisian editions bound in somewhat thicker colored twofold paper with randomly cut paper edges on hundred-five pages of A5 format. It was divided in fifteen articles illustrated with many experiments, and the very last was summary of them all. Berthollet seldom cited his colleague Fourcroy.[1189]

Lacoste was a professor of natural science at the Central Schools of the Puy-de-Dome district, famous for Pascal's barometric experiments. Zois acquired his work issued in 1803 under the title Observations of the Volcanos de l'Avergne with notes of diverse objects of the course of mineralogy Zois bind it in brown leather with flowers on the spine and marmorated red-blue inner covers full of flowers. He also described the exploration of the Sicilian volcanoes of the "immortal" Dolomieu, Haüy and the large mineralogy of Fujis de Saint-Fond.[1190]

Johan Heinrich Voigt (* 27. 6. 1751 Gotha; † 6. 9. 1823 Jena) began teaching in gymnasium in Gotha in 1774, where he published the astronomical part

of the court calendar. In 1789, he received his PhD in philosophy at the University of Jena, where he took over the Department of Mathematics, and in thirteen years he also began to teach physics. From 1786 to 1799 he took over the editing of the Magazin für das Neueste aus der Physik und Naturgeschichte, founded by its first editor, Ludwig Christian Lichtenberg (* 1737; † 1812). Voigt issued volumes 6 to 12 with numerous Hacquet's papers. From 1797 to 1806 he published twelve volumes of a similar magazine in Jena, with a slightly changed title Magazin für das Neueste Zustand der Naturkunde, in which Hacquet has no longer published. Voigt wrote papers on mathematics, fire, air, electricity, magnetism, optics, comets and the history of the calendar.

Zois also read journals of Lorenz Florenz Friedrich von Crell (* 1744 Helmstedt (Helmstädt) in Lower Saxony; † 1816 Göttingen) who became a professor of philosophy and medicine in 1773 at Helmstedt University, and after its abolition he took over the Chemistry Department in Göttingen in 1810. He published six volumes of the first German chemical journal *Chemischen Journal für die Freunde der Naturlehre, Arzneygelahrtheit, Haushaltungskunst und Manufacturen* in the city of Lemgo by publisher Mayer from 1778 to 1781. The magazine continued as Neuesten Entdeckungen der Chemie in Leipzig from 1781 to 1784, when Crell edited the volumes 1-12 with the publisher Weygandsh. In both magazines Hacquet published his works, also in supplements (Beytrage). Crell edited two volumes of *Chemisches Archiv* in 1783, which continued with volumes 1-8 as *Neues Chemisches Archiv* from 1784 to 1791. From 1784 to 1803 he published forty volumes of the *Chemische Annalen für Freunde der Naturlehre, Arzneygelahrheit, Haushaltung und Manufakturen* with J. G. Müller. From 1785 to 1790 he published six volumes of *Beiträge zu der Chem. Annalen*. In 1785 and 1786 he published five volumes of *Auswahl aller eigenthüml. Abhandl. Aus d. Neuest. Entdeckungen d. Chemie*. In 1798 he published the first volume of the magazine *Neuestes Chemisches Archiv*.[1191]

Gabriel Jars (* 1732; † 1769) from Lyon was the son of the director of the mines in Ghessy and Sain-Bel. In 1757 and 1759, together with his older companion Guillot-Duhanel,[1192] Jars travelled to Saxony, Austria, the Bohemian Lands, Tyrol, Carinthia, Styria, Schemnitz (Banská Stiavnica) and other cities of Hungarian kingdom. In 1758, Jars studied the compressed air at K. Hell's mine dewatering pump in Banská Štiavnica, which was collected as a snow after flowing- evaporating through the valve. Jars wrote about the phenomenon a year before his death. After returning from those first of his journeys across Europe, Jars was elected as a correspondent member of the Parisian Academy on 10. 1. 1761, and on 19. 5. 1765 he was elected as a regular member in the race with his first rival counter-candidate, first nominee Lavoisier. Of course, Lavoisier later as a chemist completely overshadowed most of Jars' achievements. Zois bought Jars' travelogue posthumously edited as a scientific journal, like scientific itineraries. Zois also purchased Gren's Physical Journal, where Tobias Gruber investigated Jars' vacuum phenomenon at the mine pump valve on January 1, 1791.

A particularly typical example of the Carniolan imports of Parisian science at the centre of Illyrian province was once Zois's copy of Joseph Izarn's (1766 Cahors-1834 Paris) *Leçons élémentaires de Physique*. In 1793 Izarn became the Parisian professor of physics at Lucée Bonaparte and in 1811 he was a general inspector of the university. A year prior to the publication of a book which Zois acquired, Izarn published his *Manuel du galvanisme* in 1804 after he published some guesses about the origins of meteorites. Zois' bookbinder bind Izarn's books in a blue-gray paper of A6 format reinforced in the back side with the page 38 of the printed matter about Ethiopia, and the front is reinforced with the same print of p. 35. In his first volume Izarn described bodies, attractive forces and Lavoisier's caloric with Haüy's data included. The first Izarn's panel-plate showed a vacuum experiment by burning the candles in a bowl inside the container.[1193] The last fourth panel with pictures at the end illustrated the barometer, thermometer, electrophorus, magnetic needle in nature and distillation container, while he placed the rest of the image panels between the text. The third panel-table showed the pulleys, the

second the capillarity and the Archimedes' law.[1194] The second part of that textbook covering optics and electricity was never published.

Lindenau's book of 1809 contained recommendations for barometric calculations of altitudes. Bernhard August von Lindenau was a lawyer, astronomer, politician and collector of Florentine paintings. He wrote about Venus and Mercury, and he designed his book later purchased for Zois' collection three years earlier with Lindenau's letters mailed to Zach in 1805; during the Napoleonic wars Lindenau did not finish his book due to his lack of available libraries needed for references. Lindenau's foreword was dated in Seebach's Observatory on January 1, 1809. In the last table, he published observations of Humboldt's collaborator Jabbo Oltmanns (Ottmans, *1783 Wittmund (Ostfriesland); † 1833), and the captain of engineers Pierre Alexandre Joseph Allent (1772-1837 Paris). Lindenau also respected geographic records of amateurs. Lindenau used the barometric equations of Laplace, de Luc,[1195] Mariotte and Halley.[1196] Lindenau also discussed vacuum experiments[1197] and Bošković's measurements.[1198]

Zois had an Italian translation of Davy's Agricultural Chemistry with one single copperplate, while NUK from other sources acquired the same book in German one-year earlier translation.[1199] In 1815, the Italian translations were also published in Naples and Florence, and in 1819 in Paris. Davy divided his discoveries into lessons which he taught at the Royal Institution. He was interested in the atmosphere, the plants and the improvement of soil by burning, probably because of the addition of carbon in the form of ash. He finished the book with the results of experiments, where he particularly considered Gay-Lussac's research of carbon dioxide, oxygen and hydrogen.[1200]

Jakob Anton von Zallinger zum Thum served in Dillingen in 1770. In 1776 and 1777, he taught physics in Innsbruck, followed by his lectures on theology. He was the brother of the other two important Jesuits and G. Gruber's associates. His brother, Franz Seraphim Zallinger,[1201] the professor of physics in Innsbruck from 1778, took over the chair after their brother Jacob Anton.[1202] Franz Zallinger was an important advocate of Bošković's ideas, while he published a great deal about electricity. Franz Seraphim and Jakob Anton's older brother Joannes Zallinger[1203] was also a Jesuitical physicist in Innsbruck. Jakob Anton von Zallinger independently paginated the leaves in his introduction, while in his main text he paginated every page. In the introduction he noted Newton, Bošković and even Locke.[1204] Despite of this scientific introduction, the basic text was more philosophical with logic, the philosophy of nature (metaphysics), psychology and natural theology included.

Under Gruber and Maffei's influence, baron Zois bought the basic works of Bošković's physics. Even though, unlike Baron Erberg, Zois did not acquire Newton's original works except in Hill's list of London Royal Society papers, Zois bought the basic works of Newtonians, such as the book of Englishman Keill, which was also used by the Franciscans of Novo Mesto. Zois also read the Dutchmen 'sGravesande and Musschenbroek's works; under the influence of Bošković the Jesuits of Ljubljana also purchased their books, while the Franciscans of Novo Mesto mostly used Musschenbroek's work. Above all, Zois read F. Bacon as the leading model of the scientists of the London Royal Society.

Zois bought the second edition of Hill's summaries of London RS lectures on science, botany, animals, minerals, medicine, antiques and miracles without mathematics-based science. Hill devoted his work to Martin Folker, the president of the Royal Society. Hill first began to undertake agricultural inventions which he called Arts. He praised the invention of the secretion of pure water from the salt.[1205] He described the uncontrolled eating habits of a boy,[1206] the inner parts of the fish,[1207] the

formation of jewels,[1211] plants with pure mercury in the roots,[1212] the natural formation of crystals,[1213] the Earth's layers,[1214] natural golden leaves maybe related to gold-leaf electroscope [1215] precious stones,[1216] and the Turkish wall.[1217]

Zois’ books about physics mostly described the phenomena of electricity. There, despite Bošković's, Buffon's and Franklin's influence, Zois also read a lot of the works of their antagonist Nollet. Zallinger's Jesuitical thinking about Newton in Zois’ library shows Gruber's influence. Zois also bought the book of Epp from Munich with the description of Richmann’s fatal accident.[1218] Zois also read the books of Ambschell's professor Herbert with his notes about Nollet,[1219] Bošković's friend Beccaria, Poli, and Toaldo who supported Zois' faith in the advantages of Franklin's lightning rods. Zois was deeply interested in Galvani and Volta's discovery, just like Kersnik, Marmont, Zelli and Napoleon himself; so, Zois bought today lost books of Nicholson and Davy, but he did not have the original works of Galvani or Volta. Volta could have been foreign to Zois even by the political aspects. Volta used to be a Napoleonic senator, although Volta taught in Pavia near Zois's father’s native areas in Bergamo. Davy visited Zois during his trips to the Alps, and their conversations certainly encouraged Zois reading or even active domestic experimenting with the electrical phenomena.

The Slovenian Slavistics oriented visitors liked to mention Zois's home as an image of a laboratory following the example of de la Fond and Dufieu's description in Zois’s books; Zois certainly tested the Voltaic cell at home. In his library, Zois also had many school disputations from the Habsburg monarchy and neighboring countries, including Epp's Munich notes. But Zois was less interested in mesmerism, perhaps even because of Franklin's critics of Mesmer. Zois was considered incurable after his unsuccessful searches during the first troublesome years; so, the books about Mesmer's successes in Vienna and Paris arrived in the library of the Lyceum of Ljubljana from other sources.

The books about the phlogiston theory also marked Zois’ library reading, where we find Stahl and the chief gravedigger of his theory, Lavoisier. In the meantime, Zois read other researchers of phlogiston, such as Priestley or Kirwan; Zois bought two books of both famous British researchers.

Zois was also interested in the composition of gases in the atmosphere; so, he read the descriptions of Cavallo and Priestley's experiments, as well as measurements of Jean-André De Luc, who supported Born's candidacy for the Royal Society of London. Baron Born corresponded with the baron Žiga Zois, Gruber and Hacquet, and Zois bought Born's book about crystallography; but Zois did not have Born's scientific-Freemasonic Viennese newsletter, which included the papers of Hacquet and (Tobias) Gruber.

While Zois's northern-Italian cousin Valvasor based his chemical and vacuum reflections on numerous readings by Robert Boyle, Boyle's work was only a remote history for Zois. As Zois was accompanied by a similar group of patronized fans as Boyle, Zois bought Boyle's work for his library. Nevertheless, Zois has also purchased many books on vacuum pumps, including those from Benjamin Martin's pen. Like Vega in Vienna or Vodnik in his Ljubljana News journal, Zois was also attracted by Montgolfier's ballooning. So, Cavallo, who was one of the most popular Zois's scientific sources, also liked Montgolfier's report. At the first contacts of Slovenes with the French Revolutionary armies, Vodnik, otherwise not yet fully convinced Napoleon's supporter, also started to publish the news from Paris. On 22 November 1797, Vodnik reported on André-Jacques Gernerin's Parisian "ride in the air" (October 22, 1797), when he "bled the air under the balloon" and "swam as a spruce tree on the water." At 700 m above sea level above Paris he used the modern shape of the parachute designed as an umbrella with a diameter of 10 m with sixteen ropes which did not open immediately after the jump. Vodnik reported to the residents of Ljubljana only one month after the event! Brothers Montgolfier flew fourteen years earlier, and similar attempts were soon made by the other people of Vienna. Vodnik certainly examined Zois's copy of the German translation of Montgolfier's book (1783), which was evaluated to 6 kr. In that translation, the priest Uebelacker on pages 9-36 described the history of ballooning with the achievements of Lana Terzi, Leibniz, Cavallo and the Dominican Joseph Galien's (Gallien, * 1699 Saint-Paulien in France; † 1782 Avignon) designed at the high school in Avignon in 1755. Saint-Fond devoted the book to the French field marshal, and on the panel number nine he painted Lana's boat. Among the other nine copperplates, he immortalized many details of Montgolfier's experiment with the shape of devices and the filling of the balloon on the plate 1.

In the spirit of the then changes, the transfer of novelty among the scholars acquired the readings of extremely new scientific journals, including the papers published by Zois's once confidential friend Hacquet. Their friendship slightly cooled down after Hacquet's dispute with Gruber in the autumn of 1775 and the obvious Hacquet's fiction about his own French-Russian descent. Thus, Zois acquired Gren's Annalen der Physik (1799-1812), later the leading journal of mathematical physics, Hill's report on the Royal Society of London, and acts of the Uppsala Academy. For the years 1774-1781 Zois also got the journal Der Naturforscher from Halle where Leopoldina society also worked. In Der Naturforscher Hacquet also published in 1776, 1777, and 1779. The Volumes 1-13 issued in 1774 to 1779 were edited by Johann Ernst Emmanuel Walch (* 1725; † 1778), and Johann Christian Daniel Schreiber (* 1739; † 1810) edited the volumes 14 to 30 between 1780 and 1804. The magazine was published by J. J. Gebauer, later by his widow along with their son Johan Jacob.

From 1790 to 1794 Friedrich Albrecht Carl Gren (* 1760; † 1798) issued the Journal der Physik magazine, and then renamed it to the Neues Journal der Physik until 1798. These were the predecessors of Annalen der Physik, the leading German physics journal of the nineteenth century from 1799 until 1896. Its first editor was Ludwig Wilhelm Gilbert (* 1769; † 1824). Gilbert was a professor of physics in Halle, until he arrived at the University of Leipzig in 1811; right then Zois stopped buying his magazine, as he had apparently more connections with Halle than in Leipzig. There were also problems with the Napoleonic continental blockade which provided obstacles to Zois's desires to obtain German language journals from the north. After Gilbert's death, the editorship of his magazine was taken over by Johann Christian Poggendorff. Hacquet published his letter in Gilbert's Annales, which he dated at the then Habsburgian Lviv on July 1, 1801. Since 1787, Zois has also purchased a *Magazin für die Naturkunde Helvetiens* (Zürich: Orell, Gessner, Fussli & co.). So, Zois also had Hacquet's publication printed there in 1789. Zois acquired many other periodicals, including the prints of Gesellshaft in Wippertal, Acta societatis Jablovianae of Leipzig based Prussian *Fürstliche Jablonowskische Gesellschaft der Wissenschaften*, and, of course, Laibacher Wöchenblatt of 1817-1818.

Zois bought F. Bacon's collected works issued on 354 pages in 1762. Those pages were supplemented by additional unpaged aphorisms. F. Bacon described experiments with atomism,[1220] and then he started with mathematical reasonings.[1221]

6.7.10 Swedenborg's Improvements for the Baron Zois

Emanuel Swedenborg certainly published one of the most remarkable and expensive books in his three volumes which Zois kept in his library. The work originated in Swedenborg's initial scientific era, and its purchase by no means proves any Zois's enthusiasm for the subsequent Swedenborgian spiritism published after 1742, under the possible influence of Croat Milan Nejedel, since Zois did not acquire those later books. The later cult philosopher Emanuel Swedenborg (* 1688; † 1772) studied in Uppsala, but in 1724 he refused to accept the offered mathematical chair there, although he already published many works about technical solutions. In 1731 he published *Opera philosophica et mineralogica*, which Zois did not buy. Swedenborg dedicated his first volume to Ludwig Rudolf, the Duke of Braunschweig (Bunswick) and Lunenburg (Lüneburg). Swedenborg dedicated his second volume to Wilhelm the Provincial Count of Hesse, the descendant of the owner of the first modern European Astronomical Observatory. Swedenborg dedicated his thickest third volume to Friderik I the King of the Swedes, Goths and Vandals. As it later became modern in Haüy's works, in his preface Swedenborg also divided the ether into several aspects needed for physics. He dealt with fire, magnet, air, and water vapor. He described the declination of the magnet, the merits of British astronomer David Gregory (Gregorius) and the Cartesian vortexes around the Earth.[1222] In the end, he added 28 tables with sketches, which was much less than in the third volume, where the closing sketches comprised nearly half of the volume.

In the second part, Swedenborg discussed iron ore and pits in Sweden, carbon in connection with fire, iron resources and silver. In the end, added a map of Siberia with Tobolsk in a folded A1 format and a picture of a blast furnace[1223] as later designed by Zois. In the final third volume Swedenborg described the cleaning of copper, especially in the Bohemian Lands, the melting of copper and most of all the mysterious alchemist Agrippa. Swedenborg added 89 copperplates, starting with a picture of a complete fossil skeleton from the glacier, stone houses. He noted the archaeological tools and new lifting devices.[1224] Up to his 21st illustration Swedenborg draw the engineering tools and then continued with rocks and mining up to his last 36th illustration.

Emanuel Swedenborg studied abroad from 1712 to 1714. Between 1716 and 1747 he was a member of the Swedish Mining college. He then retired and lived as a theosophist and visionary in Sweden, Germany and England. He was a member of the Swedish Royal Academy of Sciences. In 1719, he demonstrated his invention of the rolling engine to King Charles II. In 1721, he published six physical discussions in the Latin language in Amsterdam and reprinted them in Leipzig in 1722; there he drew and described a hydraulic pump on page 101. Joseph Baader developed similar pump as Swedenborg; his ideas were used by the Frenchmen Jean-André Cazalet and by César Francois Cassini de Thury's (1714-1784) cartographer engineer Henri de Saint Michel († 1793 Munich) who mapped the areas of Bavaria between 1764 and 1770.[1225] Most of the contemporaries did not know Swedenborg's discovery. Professor of chemistry at the School of Medicine at the University of Halle, Gren, in his magazine, therefore, reflected on Swedenborg's discovery in the Latin language with pictures and his own commentary. Swedenborg's discovery was promoted by the English diplomat French writer Louis Dutens (* 1730 Tours, † 1812 London), a fellow of the RS from 1775 and a publisher of Leibniz's works.[1226] In 1847 Strutt Baron Rayleigh published a translation of Swedenborg's works in London. On January 25, 2000, in the SAZU Hall in Ljubljana, the professor Inge Jonsson presented Swedenborg's work as President of the Swedish Academy of Literature, History and Antiquities.

Most of Zois's French books dedicated to the vacuum had no extraordinary propriety entries. Among all the books which have a slightly remarkable entry that could be linked to the

Illyrian provinces was mainly the Latin language propriety entry "Bibliothecae lycei labacensis" in Louis-Benjamin Francœur's (Francoeur, 1773 Paris–1849 Paris) book *Traité élémentaire de mécanique*, designed for the public instructions in its fourth Parisian edition of Bernard printed in 1807 (NUK-8511). The book was sold at bookstore of J. Klostermann son in Paris, as well as in the bookstore Klostermann son and his father in Petersburg, as we read on later glued paper on the precover. The book of A6 format was bind into a hard cardboard. Francoeur was professor of the Paris Lyceum, Examiner at Imperial Polytechnic in Paris, associate member of the Maritime department of Russian Czar, associate member of the company *d'meulation de Cambrai* and others. He was a member of the Laplace's Circle, so for his introduction he quoted a paragraph from the eighth book of Laplace's *Systéme du monde*. Francoeur dedicated his book to Laplace who was a senator, a member of the Imperial institute of sciences and arts and the author of the famous *Mécanique Céleste*. In his introduction Francoeur recommended for further reading of his students *Mécanique céleste, Systéme du monde*, as well as Lagrange, Monge, Prony, Carnot, Biot, Haüy, Legendre, and Puissant's works cited in the introduction.[1227] Francoeur praised Puissant's *Traité de Topographie* (1807) which was also used in the Parisian *École Polytechnique*.[1228] Francoeur divided the volume into four books of statics, dynamics, hydrostatics and hydrodynamics, which were clearly dealt with through the use of Lagrange-Laplace's analytical mechanics, at the end also supported with the variation calculus.

Francoeur determined the center of gravity by the old procedure of the Graz Jesuit Guldin. Francoeur also discussed the role of a vacuum in the alleged collision of two bodies in an empty space, a description of the barometric determination of heights and vacuum pumps.[1229] He resolved many of his puzzles with integrals,[1230] so the textbook certainly represented a hard reading for the students of the emerging French University of Ljubljana in its cradle. In the end, Francoeur inserted nine full-size images. In the middle of the collection of images he drew some machines; he set geometric sketches at the beginning and the end, but he did not draw any Bošković's curves which most of Bošković's fans did. Bošković curve and his whole physics certainly did not have a special high place among Parisian academics.

6.7.11 Conclusion

The French lessons and its influences in the short interval of years of Napoleonic actions and failure among Slovenes underlines the development of vacuum technology on Slovenian soil. The Slovenian or, at the very least, the city of Ljubljana dependence on French sources was unquestionable. The Parisian textbooks as the best of them all in those times would be used even if they were not supported by Napoleon's bayonets. All the decades from the French Revolution to the March Revolution, we have to the great extent the French Slovenian century from Napoleon's occupation to the roaming of the French king with A. Cauchy among his suiters in Gorizia. In this spirit, we must observe the appearance of Napoleon's monument in front of Križanke in Ljubljana, besides the Polish almost only Napoleonic monument outside France, and the Bourbonic royal tomb on Kostanjevica above Gorizia with the only French crowned head buried outside his homeland. These double ties between Slovenes and Paris are just the top of the co-operation, which connects the Slovenians to the French more closely than to any other nation, which does not share the common Slovenian border.

6.9 Books on Vacuum Experiments in Slovenia before Cathode Ray Tubes

Among the French physicists at the Auersperg's Library, there were also two copies of the Philosophical Mathematics and Philosophical Physics of the prolific Jesuit writer Pierre Gautruche (* 1602 Orléans; SJ 1621; †1681). The Baroness Oršić read out similar books. After entering the society of Jesuits, Gautruche studied in Rennes. In 1642 and 1643, he taught philosophy at the Mont à Caen College, and then he probably moved to the college of La Flèche, once attended by Descartes. In 1653, Gautruche returned to Mont à Caen as a prefect of studies and professor of theology; he exercised both duties up to his old age in 1679. From 1668 he also taught mathematics, which was of great interest to him. In 1645, he taught his best student Pierre-Daniel Huet, the later Archbishop of Avranches 100 km southwest of Caen in Normandy; Huet's critique of Cartesians appeared after Huet visited the queen Christine of Stockholm following the unhappy Descartes death there. Huet's book used to be a popular reading among the Franciscans of Ljubljana. Wolf Auersperg did not acquire Gautruche's Philosophical Physics in the first edition of 1656, but rather preferred to have five years later a Viennese reprint. Gautruche rejected the existence of a vacuum in nature, although he together with other Jesuits ensured that, of course, God can create an empty space with a miracle. He briefly summarized Torricelli's and Pascal's experiments, but he insisted on Aristotle's fear of any emptiness.[1235] He rejected astrology according to the Papal decree, and he refused the alchemy with it in the same breath. He accepted a thirty-year-old Harvey's theory of blood circulation in the bodies.[1236] Gautruche's plurality of human forms was nearer to the Franciscan Scotus that to his own religious co-brother F. Suárez.

Gautruche was the first French Jesuit who published his textbook of philosophy; the next French Jesuit Gaspard Buhon's textbook of philosophy was only published in 1723. The first edition of Gautruche's textbook was published in 1653 in his hometown Caen without any mathematical additions. Three years later he completed his work entitled the Manual of Philosophy in Mathematics as a textbook of logic, moral philosophy, metaphysics, general and experimental physics, and mathematics. He bound it with examination theses that were defended in Caen in France in 1656. In 1661, his Manual of Philosophy with Physics and mathematics was reprinted in Vienna. Volf Auersperg obtained two copies of the Viennese edition of 1661, since he frequently visited the imperial city. He cataloged both books under several different titles in his expert group of philosophy but also in his expert group of mathematics. He addresses the first part of Gautruche's textbook with its title about physics to Auersperg's library expert group of philosophical books, while the second part with mathematical title was noted in the expert group of mathematical works. The first volume of Gautruche's textbook Handbook of Philosophical Physics was Physica universalis, the second Physica particularis, the third Mathematica and the fourth Metaphysica. The baroness Oršić also bought the same item which proves its popularity among the Carniolan high society, while many others read Gautruche's history of poetry in Carniola.

1231 Promoted by Edition of Ljubljana rector Dillherr.
1232 The Jesuits of Ljubljana obtained later edition of s'Gravesande's books on Newton's physics in the year 1769, nine years after the printout in Vienna.

6.10 Three Hundred Years since Birth of Founder of First Modern Physics-chemistry Laboratory in Area of Slovenia

Bernardin Ferdinand baron Erberg's life story ended simultaneously with the suppression of Jesuit order. A quarter of millennia ago, the local Jesuit Bernardin Ferdinand baron Erberg established the very first school experimental lab in Ljubljana. He bought the instruments and books needed to fulfil his task and patronized the republication of Musschenbroek's magnetic research produced in Protestant Leyden which indicated how the border between the Catholic and Protestant scientific pursuits were almost totally removed except for the ban on Copernicans which was removed only a dozen years later. To enable those works, Bernardin was trained as a student of applied mathematics, prefect, and librarian in the most advanced Habsburg centres of learning in Graz, Trnava, Viennese University and the Viennese Theresianum where the labs like that already operated. Especially in his five years term as librarian in the newly established most elitist college for the sons of old nobility named Theresianum during the frequent visits of Ruger Bošković, Bernardin Ferdinand baron Erberg learned first-hand how to deal with advanced experiments of then popular optics, hydraulics, and geodesy of Bošković, as well as with electromagnetic and caloric experiments of his other colleagues. Bernardin Ferdinand baron Erberg published his own geodesic-cartographic work of Bohemia, while he left unfinished his similar description of his native Carniola in more literary sense to his first cousin twice removed Jožef Kalasanc Erberg who happened to be next to last great mind of that family name. Two years later, Bernardin wrote a great glorifying foreword to his deceased teacher's history of empress' family to prove the shift from physics-mathematical to the geographical-historical sciences of Bernardin as the librarian assistant of the great newly established library of Theresianum college. The move which is hardly understandable from the point of view of modern specializations was completely in the agenda of the Jesuit unprofessional approach to the several different branches of sciences in the same time based on the holistic model of the best Jesuit being at home in all sorts of knowledge resembling the last man who knew everything, the Roman Jesuit A. Kircher. The newly developed Jesuit sciences of numismatic, architecture, or Ruger Bošković' applied mathematics represented a different type of Jesuits whose primary goals were the narrower parts of mathematical sciences, which more resembled the mainstreams of Paris or London.

Bernardin Ferdinand baron Erberg's closest family members were equally successful Jesuit experts for applied mathematics which smoothed his networks worldwide. Bernardin's first cousin and his nephew were among the most eminent missionaries in America and Beijing which the Jesuits ever produced. But their best time were over after the suppression of Jesuits soon after Bernardin's death.

[1237] ARS, SI_AS 309, Legacy Inventory archive, fascicle 39, technical unit 78, litera O, no. 10, p. 68; Štuhec, 1995, 90.

The lion's share of the Erberg's writings was created under the goose pens (quill pen) of the cousin of the Jesuits Anton and Bernardin Ferdinand baron Erberg (* 10. 5. 1718 Ljubljana; † June-August 1773 Krems), namely by their uncle the Capuchin turned Protestant Matija Erberg. These prominent figures were just the top of a literally extremely efficient generation, which gave to Carniola many great scholars. Knowledge became a hobby and, at the same time, a profession of the barons Erbergs, whose scientific curiosity was almost endless. Erberg's writings dominate the exact sciences and law. With their almost singular exception of the Protestant Matija, they published a bit of theology, and almost nothing in medicine with the only exception of Erberg's student manuscript on physiology. Just Matija published economic or even agricultural files among Erbergs, whose physics had been very famous in their days. The successful rearrangement of gardens at Dol manor of Joseph Kalasanc Erberg enabled his discussion of the management of Dol horse chestnut, which was communicated to the Viennese magazine.

6.10.1 Graz and Viennese Applied Mathemaatics

After his master's degree in philosophy. B. F Erberg taught grammar in Ljubljana in 1740/41. It was great to be home again and to meet all those old good friend and relatives.In 1741/42 in Graz B.F. Erberg, Anton Bosizio, Franz Xaver Haller, Ignaz Rasp, Joseph Liesganig as their bidellus (bedel) and Michael Klaus specialized their first year of applied mathematics with Erasmus Frölich. The professor of physic was Halloy, Joseph Zanchi taught mathematics, Joseph Erberg studied his 4th last year of theology, Anton Erberg was professor and dean of Theology, Ernst baron Apfaltrer was a dean of linguistic,[1238] Karl Dollenz taught logic, Karl Andrian (Adrian, 1680 Trident-February 7, 1745 Graz) was professor of history as a dean of philosophical faculty and writer of the local history of Graz college, while the rector Willibald Krieger was appointed on 11. 5. 1740.[1239] During his specialization of mathematics called the repetition, B.F. Erberg obviously also attended Andrian's lectures of history as he recalled and noted later in 1762.

In 1742/43 in Viennese university the same class of students including B.F. Erberg, Anton Bosizio, Franz Xaver Haller, Ignaz Rasp as their bidellus, Joseph Liesganig and Michael Klaus specializedtheir second year of applied mathematics with Erasmus Frölich who was additionally also prefect of mathematical museum and the first confessor. In Catalogus[1240] they were usually noted as *Repetentes Matheseos* specializing the applied mathematics with no indication that they also specializing math in their second year. In Graz in the previous year B.F. Erberg also listened to the lectures of history, while in 1742/43 the Viennese university had a special class of three *Repetentes Historiae* where they employed Ignaz Wagenseil, Josephus Wibmer as their manductio (guide) for participating in the celebration of the Eucharist, and Mathias Köberer. The professor of mathematics and operarius was Paul Wimmer, while Hingerle from Ljubljana was still rector. Anton Hallerstein from Carinthia branch still taught controversial theology, Jacob Focky taught physics, Joseph Franz was professor of observational astronomy, while Sigismund Calles was professor of history and home confessor, probably also the head of historical specializations of his three students.

6.10.2 Graz for Ph.D.

B.F. Erberg practice between master's in philosophy and beginning of his Ph.D. Studies in theology was unusually long as it lasted for five years while most of other guys made that stuff in just two years. After he finished his specialization, B.F. Erberg additionally taught the syntax as the highest class of grammar in Graz in 1743/44.[1241] In Graz in 1743/44, B. F. Erberg's colleagues were professor of mathematics Halloy, the lecturer of principles Mathias Rieberer (1730 Murau of Upper Styria-1794 Regensburg) who taught physics in Ljubljana and published his exam theses of physics in 1758 noted in Historia Annua pp. 312-313 as *Tentamen ex physica, logico-metaphysica et mathematica ad praescriptum regiorum dectretum tenorem habita*.[1242] He also published *Gramatica Hebreica* in Graz in 1755, *Manuscripta diplomatica* in Vienna, and *Novisima Europeaee* I, 1794, He continued the works of Marko Hansiz and the lecturer-professor of poetry Andrej Friz

[1252] Uršič, 1975, 148.
[1253] Kidrič, 1926, 165.

(1711 Barcelona-1790 Gorizia) who later promoted books of Gaston Pardies and spent his last two decades as the ex-Jesuit professor of mathematics in Gorizia. In 1741 he translated from French: *Dissertatione de cognitione bruturum of Gaston Pardies SJ = Cognitionem brutorum*. The same item was promoted by Friz and Grubanovicz in Graz in 1741, and by Koller in Vienna.

The other B.F. Erberg's colleagues in Graz were Karl Dillherr (Dillher) as the professor of logic, Anton Vorster of physics, Karl Dollenz of metaphysics, B.F. Erberg's first cousin Anton Erberg as university canceller librarian reviser, dean of literature-linguistic and prefect of law exams while the rector Udalrik Bombardi was appointed beforehand. Five B.F. Erberg's students of syntax in Graz[1254] were Joannes von Arbesser (* Hadersfeld northwest of Vienna in Austria), citizen Anton Bredlin from Gezen in Tyrol, Franciscus von Egger from Graz, citizen Joseph Haubenwaler from Vorau (Voraviensis) in Upper Styria and the commoner Johannes Baptist Regale from Sarnthal (*Sarentino*) in South now Italian Tyrol. No student to talk with him in Slovenian language as B.F. Erberg was sorry to find out.

After Graz, B.F. Erberg taught poetry inside the studies of humanities in Gorizia in 1744/45.[1255] His rector was Joseph Tedeschi newly appointed on 21. 1. 1744, Anton Terzi and Joseph Zanchi of Rijeka taught casuistic, Franciscus Conti taught physics and metaphysics, Franciscus Vittinich taught logic, Joseph Carina was professor of the rhetoric and the future leading Viennese architect of Italian origin Anton Batista Izzo (1721 Košice-1793 Vienna) taught grammar. Izzo and B.F. Erberg were later again colleague in Theresianum where Izzo taught in the newly established chair of architecture and published his books in 1764-1769, including: *Tractatus de Pyrotechnica Balistica* in Vienna in 1766, *Elementa architecturae Civilis et Militaris* in Vienna in 1764-1765 with reprints up to 1777 in French translation of the Pater Jesuit Bossicart (Bossicar, Nicolaus * 1739) who served as the professor of French language in Viennese Theresianum in 1772. Izzo also published *Elementa Geographiae* in Vienna in 1769.

In 1745/46[1256] among B.F. Erberg's Classmates in Graz during his first year of theological studies were future professor of physics the Carniolan Maximilian Morautscher (1721-1806) as the son of Auersperg's manager from the castle-manor Mala vas as a part of Knežja vas in modern mayordom of Trebnje of Lower Carniola, later Zagreb physicist Franc Dabrović (1720 Požega-1767), Anton Angerer (1720-1802 Linz) as the prefect of philosophic-humanistic-controversial studies. Udalric Bombardi was still the rector appointed on 24. 11. 1743. Karl Dillherr taught metaphysics, Anton Gallyuff canons, Franciscus Grafflinden taught theology, Joseph Maister taught mathematics, Joseph Kössler taught physics, Ignaz Schreiner taught casuistic, Leopold Morelli taught sacred scripts, Joannes Priletzki taught controversy, Halloy was a prefect of astronomical observatory (Spec.) and mathematical museum, the former Ljubljana professor Sebastian Stainer monitored the exams.

6.10.3 Judenburg Probation

In 1749/50, B.F. Erberg in his 31st year entered the final stage of his Jesuit education with his third

1254 Andritsch 1711-1765, pp. 192, 194.
1255 Catalogus 1745: 9.
1256 Catalogus 1746: 10.

final probation year in upper Styrian Judenburg. He gave his feast of wows including the eternal mobility which he never endorsed as he officially never left the border of the areas of Austrian Jesuit province.

In Judenburg, B.F. Erberg's classmates among the paters of the Third Probation included his old friends later Ljubljana professor of physics the Rijeka native Franc Tricarico, Biwald's teacher of mathematics Joseph Apponyi (1718-1757) with his leading textbook,[1257] their manductio Anton Bosizio, Franc Dabrović, the astronomer Franc Weiss, and Ignaz count Rasp. Their Judenburg rector was Paul Zetlacher appointed on 27. 12. 1746 with his minister B.F. Erberg's Ljubljana compatriot Daniel Valvasor.

Figure 6-226: B.F. Erberg's botanic gardens of Theresianum in 1756 with dedication to his students Johan Josef Franz Berthold Schaffgotsch (17th October 1741-1806) and his half-brother Franz de Paula Ernst Schaffgotsch (27th December 1743 Horní Maršov- 1809 Prague) published before title page of his Notitia illustris regni Bohemiae scriptorum geographica et chorographica, Vienna: Joseph Kurtzböck, 1760

There was no teaching in good old Judenburg, just prayers and subterranean fights for future great jobs and positions. B.F. Erberg finally achieved his goal except for his dreamed missions. He was chosen to reform the exact part of Ljubljana studies in accordance to his late first cousin Anton Erberg's textbook modified by G. van Swieten's new Theresian reforms.

6.10.4 Ljubljana Lab: Bernardin Ferdinand Erberg Reforms the Physics Lecturing in Ljubljana

In Ljubljana in 1757/58 (Catalogus 1758: 15-16) B.F. Erberg taught mathematics and wrote the diary of the college while Franciscus Tricarico taught physics, Ernst baron Apfaltrer headed the seminary, Kart Dillherr was the prefect of higher school as lecturer on casuistic, Anton Maisterr was prefect of Lower School, Joseph Erberg taught casuistic, Mathias Riebertd taught logic and metaphysics, Moraučer was procurator and old rector Sigismund Lichtenberg was the first confessor, the future Graz physicist Leopold Biwald taught rhetoric, Anton count Hohenwart lectured on poetry Francis Weneg taught syntax, and Joseph Carl was rector appointed in 26 4. 1745.

6.10.4.1 Organization of the Ljubljana Physics-Mathematical Cabinet

Erbergs helped Empress Maria Theresa in modernizing Ljubljana's higher studies. A week before the birth of Jurij Vega on 16. 3. 1754 for the purchase of instruments they earmarked the sum of 500 florins, almost half of the annual income of Dol manor.[1258] The census of fifty-one (in fact fifty-five) unnumbered devices for physics-mathematical experiments of Ljubljana Jesuit philosophical studies was compiled by professor of mathematics and physics Bernardin Ferdinand Erberg on 17. 9. 1755.[1259] With the annual grant of the physics cabinet 25 florins B.F. Erberg could have bought two or three new instruments every year if those gold coins were not used to maintain old devices. In 1767, after B.F. Erberg's departure the new metal casting manufacturer Jakob Samassa took care of the repair in the physics cabinet of the Jesuit college in Ljubljana, when Samassa's friend Gruber came to Ljubljana.

Erberg listed the instruments by the sectors in which they were supposed to serve. He considered

[1257] Losada Prada, Keri, Apponyi, 1752, 1753-1754. As Keri and Josef Apponyi's promotive works published with Mitterpacher de Mitternburg and Kery (Keri, Sommervogel, 1890-1900, 1: 479) primary as the work of Salamanca professor Losada.

[1258] Historia annua, 1754, 284; Smole 1982, 135.

[1259] Müllner, 1901, 171-172; Schmidt, 1963, 1: 303; SI_AS 6, Komora in reprezentanca (Chamber and representation), Fasc. 40, 17 September 1755.

the individual parts of mechanics as separate units. The census started with gadgets for astronomy, followed by mathematical instruments, a collection of tools for measurement, tools to show magnetism, geodesy, acoustics, gases, heat, mechanics, optics and electricity. Only a few devices were listed outside of this order, which did not exactly follow the sequence of physics lectures in higher studies.

Figure 6-227: B.F. Erberg's map of Prague areas published at the end of his Notitia illustris regni Bohemiae scriptorum geographica et chorographica, Vienna: Joseph Kurtzböck, 1760

If mechanical instruments also include acoustics, B.F. Erberg's list included twenty-four, that is, almost half of the teaching materials for mechanics. Many facilities for the exploration of light indicate that Newton's work from the years 1672 and 1704 and his optics became the most important experimental science. In addition to devices for displaying the laws of geometric optics, they acquired four microscopes, prisms and cones. Many microscopes certainly proved B.F. Erberg's interest in biology, also indicated by his alleged manuscript that compares the operation of the eye and the camera.[1260]

Among the first astronomical devices in the Jesuit college in Ljubljana, they acquired an armillary sphere (Sphaera Armillaris) in 1706. Bernardin Ferdinand Erberg supplemented the collection with two globes and a stellar atlas. The Ptolemaic model has already been completely abandoned, since Bernardin Ferdinand Erberg acquired the model of the universe only by Tycho and Copernicus's system. In doing so, he bravely hurried a bit, as he bought them two years before the Catholics were officially allowed to teach Copernicus's presumption. So, was really a little premature, but with enough caution because Ljubljana was far enough for Roman headquarters.

Table 6-27: Devices on the Jesuit College in Ljubljana according to Erberg's census on 17 September 1755

Branch of Science	Number of devices
Mathematics	2
Mechanics	24
Solid state permeability & cohesion	6+2
Tools for measurements	2
Fluids	4
Acoustics	1
Geodesy	3+1
Vacuum, overpressure, gases	8
Optics	13
Astronomy	7
Heat & Meteorology	2
Electricity	1
Magnetism	1
Total	51 (54)

In college they probably purchased a telescope before the year 1761, when J. Schöttl in Ljubljana observed the transit of Venus across the face of the sun with his sixteen feet long binocular. The measurements of the Jesuit surveyors were encouraged by B.F. Erberg with his acquisition of geodetics tools in Ljubljana in 1755. Calculation of the length of the meridian has become a kind of parade horse of Jesuit scientists. In the Slovenian part of Styria, the meridian was measured by the Jesuit Liesganig, who also taught Gabriel Gruber. Of course, B.F. Erberg knew the triangulation, with which his first cousin Innocent Erberg and Innocent's nephew A. Hallerstein helped to draw down the maps of South America and of the Far East. In the beginning of April 1757 and again on 9 March 1758, Bošković himself visited Ljubljana just before B.F. Erberg's went to Theresianum. Bošković explained to Carniolan folks the new

[1260] SI_AS 1073. Collection of manuscripts 242 r: Erberg, about 1740, 58.

principles of experimental teaching and geodetic measurements at territories of the Papal States, which made him famous during the years 1750-1756.[1261] At the time of B.F. Erberg's purchases of experimental experiments in Ljubljana the electricity and magnetism were still the marginal branches of physics, more suitable for the appealing popular display of exceptional phenomena, than for the useful physics way of thinking. In 1755, the special devices for the study of magnetism and heat in Erberg's collection did not yet exist, except insofar as they were needed for geodetic and meteorological research. Magnetism played a peripheral role until the magnetic force was measured at the end of the 18th century. In Erberg's census from 1755 we miss the models of steam engine, particularly economical steam digester as the forerunner of the pressure cooker under high pressure, in which the Frenchman Denis Papin cook a festive lunch for the King of England in 1680. In 1755 Erberg in Ljubljana brought the whole facility to demonstrate the resistance of the air, gravitational force and laws hydrostatics. He devoted eight tools to research vacuum, pressure and air resistance, as these questions obviously inspired his curiosity. He pumped out the air with the air pump probably manufactured by Musschenbroek in Leyden and convinced his students that sound could not pass through an empty space, but the thermal radiation and light could. Robert Boyle proved that fact a century ago; Erbergs in Dol manor already thermal were already aware of that since they could borrow a complete collection of Boyle's books from the library of their friend Valvasor at Bogenšperk. B.F. Erberg also bought the Magdeburg hemispheres of Boyle's friend and rival Otto Guericke for the Jesuit lessons in Ljubljana, along with a device to illustrate Galilean's assumptions about movement in an empty space. Both century old experiments were a real attractions for the eyes of the pupils. Of course, Erberg only demonstrated his experiments to his student boys ex cathedra, as he did not have enough tools for the pupils' independent experimenting. In 1755, B.F. Erberg began to use three scales in the Jesuit College of Ljubljana, among them 'sGravesande's and hydraulic. Precise weighing in the Lavoisier Parisian Laboratory shortly after Erberg's death enabled the advancement of chemistry. Similar devices were purchased by the Jesuit Orlando (1723-1784) in Trieste gradually from 1753 until the ban of the Jesuits two decades later. Orlando studied philosophy in Graz when B.F. Erberg taught grammar there, so they knew each other very well and exchanged their experiences of experimenting and pedagogy.

6.10.4.2 Bernardin Ferdinand Erberg Updates the School Library

B.F. Erberg arranged his Ljubljana Physics Cabinet primarily in Paris and Leiden patterns. He was aware that the new experimental devices would not be enough. The devices needed instructions for their use. In 1754, just prior to the acquisition of instruments, B.F. Erberg has bought much more modern mathematical and physics works compared to his predecessors, including Ozanam's instructions for entertaining experiments (1723), Musschenbroek's research with the addition of pneumatic devices (version of 1739), the first part of Désaguliers' experimental physics (version 1751) and five volumes of German translations of the Parisian Academicians' publications from 1692-1715 printed in Wroclaw in 1748-1750. In hat Parisian notes B.F. Erberg checked the findings of astronomers Cassini, Philippe de la Hire (* 1640; † 1718), René-Antoine Ferchault de Réaumur (* 1683; † 1757), Amontons, and Swiss Johann Bernoulli (* 1667; † 1748). Their works were classified according to their observed topics in Parisian academic journal. In the same year, B.F. Erberg bought at least two other Musschenbroek's Latin books and even reprinted-promoted Musschenbroek discussion on magnetism in Latin translation in Ljubljana. B.F. Erberg wrote all his other works in Latin, with the only exception of the German student manuscript on physiology from the lectures of his paternal first cousin Anton Erberg in Vienna in 1738/39 if that were not the later Jožef Kalasanc Erberg's notes.[1262]

When complementing the Jesuit library, Bernardin Ferdinand Erberg was inspired by the richly equipped collections of his relatives Erbergs, who subsequently merged their libraries in the Dol Manor. Despite the modernization of Bernardin Ferdinand Erberg, in the library of the Ljubljana college still dominated mathematical works of Jesuit writers like Dechales, Tacquet, Schott,

[1261] Marković, 1968, 320-321.

[1262] SI_AS 1073, Collection of Manuscripts , 89 r, (178 r), 242 r.

Gooden, Steinmeyer, Federico Sanuitali, Hell, Wiedeburg, Mario Bettini, Frölich and Roman professors Clavius, Kircher and Bošković. They still insisted on geometric derivations, although a more modern infinitesimal calculus was increasingly popular. The Jesuits of Ljubljana acquired five books with dated propriety entries upon the beginning of their lesson of mathematics at a higher level between 1706 and 1709. Most of them were purchased by Bernardin Ferdinand Erberg during his course of reforms in mathematics classes between 1750 and 1758 when he taught mathematics and physics in Ljubljana. Initially, the Jesuits procured only Latin books until Erberg began purchasing newer works written in the living vernacular languages. At seven mathematical-physics and astronomical books, B.F. Erberg's bookplate explicitly stated the year of purchase (Wolff 1733, Ozanam 1723, Wiedeburg 1726, Bošković 1755, Hire 1725 Manfredi 1750, Marinoni, 1745), while in the other thirteen mathematical and astronomical books he did not (Wolff 1756, Genovesi, Gooden, Musschenbroek, Magalotti, Ritter, Clavius, Lana, Brixianus, Sanuitali, Copernicus, Reinhold and Commandino bind to Kepler). In the middle of the 18th century, B.F. Erberg acquired altogether forty-two books on the exact sciences, but he was not their only user, since the name of I. Redlhamer (1719 Erlauf-1794), who used to lecture on physics in Ljubljana in 1755/56, was written on the cover of Vater's Experimental Physics. At the end of the lectures, Redlhamer conducted a public examination of candidates with an experimental presentation of 160 different physics and mathematical queries. The event was a real treat for the eyes, as among the educated listeners the Jesuit scribe counted thirty counts and barons, among them certainly also the folks from Dol castle. The performance ended with a symphonic concert and a theater, and their examination questions were printed in Trieste.[1263] The book of Christian Vater (1651-1732), *Physica experimentalis systematica in usum studiosae iuventutis*, Witebergae, 1734[1264] got a bookplate: Ex. Liberales artes P. Ignat. Redlhamer Inscriptus Bibl. Phil. Coll. Labac S.J. 1755. The Wittenberg physician and university professor Christian Vater was a father of anatomist-botanic Abraham Vater (1684 Wittenberg-1751 Wittenberg).

Erberg donated many learned books in parchment covers to his Ljubljana college. Thus, the label signed Ozanam's work beyond the headlines read that Councilor court chamber in Vienna Ljubljana native Franc Henrik (Joseph) baron Raigersfeld (* 1697, † 1760) bestowed that book upon Viennese mathematics student B.F. Erberg on of 9. 6. 1743. Donor F.H. Raigersfeld was closely connected both with the Erbergs and the Jesuits. On 10 June 1726, he married Maria Anne Elizabeth Erberg (* 1710; † 1752). The bride was the daughter of B.F. Erberg's cousin, Baron Franc Michael Erberg (* 1679; † 1760), a member of the Provincial Court of Carniola. Maria Anne's fourth son, the Jesuit Franc Borgia Karel (* 1736; SJ 1752; † 1800), was professor of history at the Theresianum between 1767-1773, initially under the new prefect B.F. Erberg. Maria Anne's youngest son, Michael Raigersfeld, was right then considered the most talented student at the Theresianum of Vienna. Probably B.F. Erberg mastered French, but he did not read Dutch or English, which were also represented among the books of the Jesuit library in Ljubljana. He also bought a letters of the Secretary of Florentine Academy Magalotti, Italian books of Della Torre and Nollet, so he must have read Italian. In the 1750s, B.F. Erberg wrote nearly half of the Jesuit propriety entries on the cover of books written in the later dominant Newtonian and Musschenbroek's orientations, which he also obtained from Musschenbroek's (Protestant) Leiden. He might find new astronomical literature in Nuremberg, but he bought a lot of items in nearby Venice and in the city of Brescia. He acquired a relatively few books in Rome, which until then was the main provider of textbooks for Jesuit schools. Most of Erberg's books went beyond the textbook level, as they focused on specific issues and were equipped with modern descriptions of measurements and experiments. Ozanam's manual, which Raigersfeld donated to Erberg, draws from the typical Parisian tradition of entertaining mathematics and physics developed just before the ideas of Ozanam's coeval Newton prevailed in France. Ozanam published four parts; Raigersfeld took his time and wrote down dedications for B.F. Erberg in all four of them. The text contained a total of 1,672 pages full of instructions for experiments, which the professor should indicate to students. The first part of the book dealt with arithmetic, geometry, music and optics, the other with sunshine, cosmography and mechanics, the third with pyrotechnics and

physics, and the last with natural and artificial lamps, permanent lanterns and various attractions. Especially extensive were the instructions for the preparation of luminophores, which gave young people the enthusiasm for many interesting experiments. Ozanam visited London and Oxford for several months in May 1701, so he learned all about Newton's achievements first-hand. He was not a first-class mathematician, but mostly a popularizer, although in 1711 he became an associate member of the Parisian Academy in the class of Mechanics. Since 1678, a member of the Parisian Academy has also been Philippe de la Hire (* 1640; † 1718), whose Astronomical tables B.F. Erberg also bought for the Jesuit library. Ozanam's Mathematical Recreations have been printed in many new editions for a whole century. B.F. Erberg's collaborator Franjo Orlando bought several Ozanam works in Trieste. Later in the 19th century Ozanam's relatives of Jewish origin joined French Catholic associations together with Cauchy in futile efforts to restore the dominance of the Jesuits in the school pedagogy.

After the Peace of Utrecht in 1713, the Habsburg monarchy occupied the areas of modern Belgium with the city of Liège included under the name of the Habsburg Netherlands. So, the Slovenes were with Brussels for some time in a common country long before EU. The Dutch Jansenists van Swieten who used to be Boerhaave and Musschenbroek's student in Leiden, was appointed as one of the leaders of the Imperial study committee in Vienna, to reform up to date mainly Jesuitical schools in 1760.[1265] Thus, he gladly approved the purchases of six Musschenbroek works from the years 1739-1768. In 1754, B.F. Erberg issued one and bought three Musschenbroek's books. Of course, the Jesuit B.F. Erberg could not quite follow Van Swieten's more liberal worldview. However, in his lectures, he undoubtedly defended the ideas of van Swieten's Leiden teachers' physics. We only recognize part of the books that B.F. Erberg used in physics lectures at the Jesuit college in Ljubljana since several perished in the fire of 6. 6. 1774. After Erberg's departure to Vienna (1759) in the librarians did not bookplate the years of purchase the Jesuit books anymore, but only noted the name of their library. After 1754, the head of the Jesuit library in Ljubljana was the rector, and his assistant was a lecturer of lower studies.

Procurement of the devices and books was a testimony of B.F. Erberg's interest in the research of solid matter, heat, and magnetism. He was especially close to Musschenbroek, whose measurements of water density was also quoted by Mairan.[1266] In his introduction to the second book, Désaguliers (1751) quoted Musschenbroek as his friend and adviser. In 1756, B.F. Erberg wrote down the proprietary bookplate of the Jesuit College of Ljubljana in the oldest known work of Newton, a 63-year-old Newtonian edition of Bernard Varen's (1622 Hitzacker, Lower Saxony-1650) General Geography to express B.F. Erberg's later fascination with mapmaking geography.[1267] Ljubljana copy of Newton's adaptation of Varen was originally owned by the Styrian guy Jožef Kraus (* 11. 9. 1678 Neumarkt in Styria along the upper Mura River; SJ 6 10 1696 Judenburg; † 16. 11. 1718, Osijek) who worked as Ljubljana professor of mathematics and physics. In 1717, Kraus published a book on geography, physics and mathematics in Ljubljana, but only in the following year he wrote his bookplate on the inner cover of Newton's adaptation of Varen's book. So, he did not quote Newton in his work, certainly because of the problems he could have faced through public support for the Protestant Newton. Later, the problem was no longer acute in 1756 when B.F. Erberg officially wrote his bookplate in the Copernican books in the Ljubljana Jesuitical library. Two years later in the index of 1758 the Catholic Congregation abolished the ban on books about the real Earth's movement also advocated by Newton. The advanced educated literati of Erberg's family already belonged to best Carniolan scientists. Newton arranged Varen's book for his lectures at Cambridge to carefully replace the Cartesian description of the Earth with his own; in fact, he did not make a lot of changes since he retained all the chapters from Varen's original print (1650) in the fourth edition in Jena. Newton only slightly increased the Jena format in his edition and published 864 pages instead of the original 786; Newton added just over 10 percent of his own findings. He corrected some errors by using the new Snellius measurement of the Earth's range: he corrected Varen's distance of forty Earth's radii between the Moon and the Earth to 52. Newton improved and supplemented the values for the geographical coordinates of individual important sites, as the patient Varen did not manage to write the Longitude of thirty-one cases. Jurin added numerous quotes from English Newtonians, as well as French academics Huygens and Cassini, to the later republication of Newton's improvements to Varen's work. He retained 32 original Newton's illustrations, adding thirteen new diagrams. He also included Halley's plan of the so-called trade winds that helped the sailings of European entrepreneurs, and added geographical coordinates for 152 places; despite Cotes' ideas, this proposal did not follow

[1267] Varen, Bernhard. 1650. *Bernhardi Vareni med. d. Geographia generalis*. Amsterdam: Elsevier. Newton's adaptation: 1693. Jena: Croker. Russian Translation. 1718. Moscow.

the plan of Halley natural magnetism.[1268] Newton's version of Varen had mathematical and physical introduction, the chapters have been devoted to the manufacture of ships and navigation. Navigation was of great interest for Dol Erbergs and their relatives Raigersfeld, since the husband of Mary Ann Elizabeth Baroness Erberg, the Carniolan shipper Franc Henrik Raigersfeld successfully dealt with overseas trade. Raigersfeld became president of the commercial conscience and chamber councilor.[1269] He traded with the Portuguese as an associate of the French company d'Orlando and a member of the newly formed Oriental Society between 1721-1724. With his connections in Portugal, he also helped his wife's relative Hallerstein, when he was waiting in Lisbon for a boat for the Far East. As a member of the new Carniolan nobility, he supported Gruber's voyage and towing of ships along the Sava River, especially with Zidani most Jožef Kalasanc Erberg included F.H. Raigersfeld's legacy, family correspondence of Raigersfeld and letter of F.H. Raigersfeld's son Karel-Charles Franc Borgia Raigersfeld (* 1736; SJ; † 1800),[1270] who was professor of history at the Theresianum academy been between 1767-1773.

Ljubljana Jesuits' first issue of Varen's work was obtained from their confreres from Rijeka. Today, in the NUK, we even find the Russian translation of Varen, made according to the order of Peter the Great. Peter sought to improve the Russian navy and had to expand the original pocket Varen's edition to a large format. Unfortunately, the stylized initials of the original Carniolan owner of the Russian translation today do not tell us who her or she was. Erbergs also had Newton's Principles in their Dol Library in the third Latin edition, the first print outside England, published in Amsterdam in 1723; the item was estimated at 1 florin.[1271] Even their Newton's Optics was bought in Amsterdam, but in French translation. Thus, Erbergs had the oldest examples of Newton's works on Carniolan soil and we have them rightfully for the first Newtonians in the central part of modern Slovenia. Their friend, Zois, had 'sGravesande Venetian adaptation of Newton's philosophy (1749); Erberg acquired it in the first Leiden Latin edition of 1725. Erbergs also had Eusebio Squari's (1738) Venetian explanation of the northern light according to Newton's principles. Valvasor had indeed bought nearly all the books of Newton's role model Boyle and Newton's teacher Barrow. But he did not buy Newton's works, as it was probably too early to fully acknowledge Newton at the time of Valvasor's British journey despite of Valvasor's friendship with Newton's friend E. Halley. In 1678 in Ljubljana, the bookseller Mayr has not yet been able to sell the books of Newton, so Mayr offered Newton's opposition including the works of the English Cartesians as was Antoine Le Grand (* 1629, † 1699) with a completely new history of science experiments. Of course, Carniolan folks could have read Newton's early works published in London's Philosophical Transactions which Valvasor bought and Mayr offered in his Ljubljana store. Anyway, the Manor Dol used to be the center of Carniolan defenders Newton's doctrine for several decades before they began to take root in Bošković's ideas.

6.10.4.3 Bernardin Ferdinand Erberg's Edition of Musschenbroek's Work about Magnets

The Ljubljana Jesuits tried to follow the development of physics worldwide. An experimental manual of distinguished Dutch physicist Peter van Musschenbroek witnesses these efforts. In 1754, the Latin translation of the manual was printed at the same time in Vienna and with the professor B.F. Erberg's exam thesis in Ljubljana. Unlike the Ljubljana edition, the Viennese edition did not include any exams. The Ljubljana edition of 1754 has noted Ljubljana as the place of editing-printing. The printer was not specifically mentioned, although printers were usually referred to in examinations thesis. In the same year in 1754, B.F. Erberg purchased at least three Musschenbroek books for his College of Ljubljana. Among them was the Essay on Physics, where Musschenbroek examined the questions of vacuum in the third chapter of the first volume on pages 60-74. In contrast to the Cartesians, he claimed that there was more empty space than full spaces worldwide. He wrongly considered that water was cooling faster in an empty space than in the air, allegedly evidenced by the impossibility of the burning in an empty space.[1272] He acknowledged the necessity of fresh air for divers

Figure 6-228: Erberg’s library stamp seal as coat of arms by Greek inscription in the middle of the list of his books about physics (Erberg, 1798, 100).

Figure 6-229 A different baron Erberg’s seal with a crown was designated in Erberg's books. Here we see this seal under the experiment of the Carniolan literary history of Jožef Kalasanc written on the winter afternoons in 1825 (kept in the National Museum of Ljubljana).

but still hardly guessed the role of oxygen in combustion, which was successfully investigated only later by Priestley, Scheele and, above all, by Lavoisier. In 1731, Musschenbroek devised a special device for the study of the solid-state distribution of heat called the pyrometer. During heating, the tube of the pyrometer broadened and the toothed wheel rotated on the indicator. The device could be used as a relatively unreliable thermometer that did not provide useful results.

On 11 October 1745 Kleist of Pomerania described the discovery of an electric capacitor in the newspaper. In the next issue of the same magazine, Musschenbroek immediately announced that he had already put the same device on work before Kleist. Since Musschenbroek published his popular textbooks, they called the device a Leiden jar after his birthplace where he lectured at the university. Ewald Jürgens von Kleist (1700-1748) of the highest Prussian nobility used to be Musschenbroek’s eight years younger fellow Leyden student but Kleist seemingly did not fight much for his priority as he died less than three years after his discovery. He was certainly aware of its significance while today there has never been a greater need to store electricity.

The Leiden jar is certainly the most important Musschenbroek discovery, on which his reputation is based. The son of B.F. Erberg's first cousin, A. Hallerstein, tested the Leiden jar in Beijing and paved his way toward the Voltaic electrophorus and pile. Bernardin Ferdinand Erberg, as the last among his purchased devices, listed "Machina electrica" in 1755. That could be a Leiden jar or a spindle for friction electricity. Musschenbroeck published his results on 283 Latin pages with ten copper plates in many tables. Eight years after the publication of his Leiden jar Discovery, in September 1754, B.F. Erberg published a translation of Musschenbroek's magnetic research for the Society of Jesus in Ljubljana. The Ljubljana edition had two cover pages and eleven pages with sixty-five examination theses. The theses were followed by Musschenbroek’s experiments with magnets, which Musschenbroek ultimately illustrated with ten full-length sketches.

6.10.4.4 Librarians Erberg

The Dol manor based Erbergs as book lovers have also proved themselves as the librarians of various

Jesuit institutions. The later missionary, magister Innocent Erberg, was an assistant librarian between 1718 and 1719, while at the same time he taught grammar and syntax at the Lower School.[1273] The last Jesuitical librarian in Ljubljana was Innocent's nephew, Janez Jožef Lucius Erberg (* 11 February 1712 Ljubljana; SJ 18 October 1732 Vienna; † 29 June 1787 Dol). In 1730, he was praised for the best knowledge of Latin at Ljubljana's lower studies,[1274] just like his uncle Innocence before him. Eight years later, Janez Jožef Lucius taught in the lower grades of the Ljubljana grammar school. Between 1746 and 1750, he taught ethics, theology and philosophy at the college in Klagenfurt. From 1752 to 1754 he was a professor of theology and confessor in Gorizia. Between 1755-1773 he was a professor of theology, prefect, librarian and confessor in Ljubljana in collaboration with his first cousin once removed B.F. Erberg. In their reports, the Jesuits of Ljubljana continuously enrolled Janez Jožef Lucius Erberg in the second place immediately after the rector, which by itself proved his exceptional importance. In Ljubljana, he was associating with Francis Xavier Wulfen, who in 1763 taught physics according to Newton's science in Ljubljana. They often surveyed the plants of the Kamnik Alps accompanied by the count Jurij II Sigmund Hohenwart (* 1713) and his son, the Jesuits' pupil count Sigmund Hohenwart (* 7. 6. 1745 Celje; † 1825 Linz).[1275] During the school year they searched for the plants in vicinity of Ljubljana, and during the holidays they enjoyed longer tours to the Alps. The son of the cousin of Sigmund Hohenwart, the count Franc Jožef Hanibal Hohenwart (* 24th of May 1771 Ljubljana; 1844 Kolovec), was married to the Baroness Margareta Felicita Henrieta Erberg (* 1764 Ljubljana; † 1851 Ljubljana), the younger sister of Jožef Kalasanc Erberg. After the ban of the Jesuits, Janez Jožef Lucius Erberg officially replaced the rector Rieger, who immediately left Ljubljana after hearing the evil public reading of the letter of ban on Jesuits. Two months later, on 29 November 1773, the former Jesuit librarian Janez Jožef Lucius showed to the commission for the inventory of the property of the former Jesuits twenty-four written ternions of the library catalog that were later lost. The ternion is a section of paper for a book containing three double leaves or twelve pages, so the catalog was by no means small. The Commission noted with surprise that the former Jesuit library was unregulated. So, they could not verify if Erberg's catalog matched the actual state of the books. The Librarian J.J.L. Erberg did not specifically explain the disorder. In any case, the Emperor Joseph II warned against the abuses if the publication of the ban on the Jesuits would delay. In fact, the disappearance of catalogue of Ljubljana Jesuits' books was one of such abuses although it is today not clear who hided the catalogue and stole the valuable books, the Jesuits or the greedy folks who administrated their former property, or both in cooperation. The unsurpassable supposed disorder of the Jesuit Library of Ljubljana is certainly very surprising and may have been the result of exceptional circumstances related to the ban of the Jesuits in Ljubljana and the fire of 1774. According to other sources, twenty-four ternions of the catalog should have been compiled by Wangg and Dolhopff. On 22 January 1774, their catalog was sent to the provincial headquarters, which sent the file to Vienna two days later. The provincial councilor baron Michael Raigersfeld, the son of baroness Marie Anne Elizabeth Erberg, mentioned in his report to the court chamber only sixteen ternions. In any case, we do not know of any of them today. On the initiative of M. Raigersfeld, the former Jesuit librarian from Steyer Wang, and Dolhopff of Vienna, immediately after the new year of 1774 began cataloging the previous Jesuitical books. On 28 June 1774, a fire broke out and damaged the books worth 12,000 florins, but mostly mathematical and philosophical works were saved.[1276] When the first public scientific library was founded in Ljubljana in 1774, the library of the Agricultural Society and the library treasures of the dismantled monasteries were set up in Ljubljana. The Baron Janez Jožef Lucius Erberg left the management of the new library to his former Jesuit colleague Innocent baron Taufferer (* 1. 1. 1722 Turn by Višnja Gora (Mountain) SJ 28. 10. 1738 Vienna; † 14. 1. 1794 Ljubljana). Both were Carniolan barons, so they easily agreed. The handover was facilitated by a sibling bond as they were fifth cousins once removed, since J.F.L. Erberg was an uncle of Anton Krištof Dinzl von Angerburg († 1727), married to the aunt of Innocent Taufferer. In 1760, Innocent Taufferer taught physics at the College of Ljubljana.

[1276] Dolar, 1974, 9-13; SI_AS 7/XI Ecclesiastica, Lit J, num. 23, vol. 1, 1774.

The librarians of baron Erberg's family have also established themselves outside Ljubljana. Erberg's younger brother Innocent (Franc Ksaver) Anton Erberg served at the College of Ljubljana until 1719, and then, during his studies in theology, for four years he was a librarian in Graz. In December 1744, he became the Rector of Ljubljana. Anton's cousin Bernardin Ferdinand Erberg was after the departure from Ljubljana between 1759 and 1763 Librarian at the elite school Theresianum for noble sons, and in 1767 the Viennese Jesuit librarian of the college. Because of their rich experience in the Jesuit libraries, the barons Erberg of course, hired librarians to regulate their private collection of books in Dol. Jožef Kalasanc Erberg collaborated with the librarian of the Theresian Academy, the priest Francesco Herbitz (Frančišek Borgia, 1752/1753 Jesenice–After 1809 Vienna). They shared common interests in plants and Carniola also because of Herbitz herbal surname. Between 1808 and 1810, somewhat thirsty Janez Anton Suppanschitsch (Zupančič, 1785 Ljubljana–1833 Koper) took care of Erberg's books until he illegally sold two valuables and Jožef Kalasanc quickly got rid of him. In December 1821, Jožef Kalasanc employed the librarian Anton Rožič. In less than two years, he dismissed him with a retribution without a certificate in June or July 1823, regardless of Rožič's book Krain bis zum Jahre 1823,[1277] which Rožič completed in the year 1824. From Trieste, Rožič sent the item to the baron J.K. Erberg, but the work was not welcomed. Rožič was from the Moravče parish above Dol, but did not finish his philosophical studies in Ljubljana despite Rožič's studies of poetry in lower school of Ljubljana in 1806.[1278] Since he was looking in vain for various jobs in Vienna, he was sent home in exile and in 1821 he knocked on Erberg's door[1279]. Later, he was expelled to his home again where he died.

J.K. Erberg valued Schönleben as Valvasor's guide and Vega was noted with two sons and a daughter,[1280] Also, Hacquet, F. Hladnik[1281] and Scopoli,[1282] Anton Erberg's moral philosophy[1283] with dogmatic, and Šemrl were highly valued.[1284] J.K. Erberg did not mention Gruber, although he described the deepening of the canal between 1823-1829.[1285] He specifically mentioned the rebellion against Napoleon in the Duchy of Kočevje and Novo mesto[1286] and Nugent.[1287] J.K. Erberg's local history of Carniola concluded with a description of the war events in Europe by a professed enlightened thought.[1288] The custodians of J.K. Erberg's library were working in the southern of the two newly constructed pavilions. Erberg's led one of the first public libraries of Carniola in 1831-1880. Jožef Kalasanc liked the highly capable curator of his museum and library, Jožef Vode (Ude), to whom he left many goods in his last will. Unfortunately, there was no record of borrowed books. The Erberg library catalogue resembled the catalogue that Filip Terpin left us in the Upper Castle (Gornji Grad) Ljubljana Diocese Library where Terpin half of a century earlier borrowed the books to Schönleben and others by deleting the titles of returned books. The Erbergs knew the Upper-Castle (Gornji Grad) library well, since the uncle of Jožef Kalasanc, the Dol baron Ferdinand Benedict Gabrijel Erberg (1722-1796), was the headmaster in the Upper Castle between 1746-1751. The priest Ferdinand Benedict Gabriel then took care of his souls in Moravče parish close to his home of Dol manor until he became the dean in Ljubljana in 1760. The modern Dol library named after Jurij Vega was opened in the local school in 1854. It is the heir to one of the oldest public libraries in the Slovenian territory.

The north part of Erberg's pavilion as "art cabinet" became the first museum in the country later called Slovenia.[1289] Jožef Kalasanc Erberg was also interested in the history of Carniola Libraries before he opened his own library to the readers in the newly built Upper Pavilion. His own research was dedicated to the eleventh among his queries spelled as: "Where and when were gathered in Carniolan excellent libraries?" He did not just highlight his own Erberg's libraries, but also the libraries of Auersperg, Valvasor, a Jesuit library

turned into Lyceum library, and the first public library of the Academy Operosorum.[1290]

6.10.4.5 Theresianum Library and Prefecture

In 1728 Anton Erberg republished – patronized Karl Granelli's geographical-topographical book, mostly the part dealing with Carniola and other parts of Inner Austria. Anton paternal first cousin B.F. Erberg decided to update Anton's work, but his superiors wanted him to make the similar research on Bohemia first because B.F. Erberg had all the best opportunities as the assistant librarian of Khel in Theresianum.

As the obedient Jesuit, B.F. Erberg worked hard and produced a great book B.F. Erberg did not finish his similar work focused on Carniola which later updated his first cousin twice removed Jožef Kalasanc Erberg in literary areas. B.F. Erberg relied on Johann Christoph Müller's (1673-1721) work.[1291] Johann Christoph Müller's elder brother married the daughter of Müller's teacher astronomer Georg Christoph Eimmart (* 1638; † 1705).[1292]

After his successful mapmaking, B.F. Erberg turned to the historical studies. In 1762, he republished the work of his deceased professor of history Andrian. Erberg's collaborator Riegger the professor of German Josephine Law, Natural and International Law, in Innsbruck in 1733-1755, afterwards in Viennese University and Theresianum. He became the Ritter (knight) on 8. 1. 1762. The publication was paid by the students of Paul Josef von Riegger. After Riegger's dedications to the empress and B.F. Erberg's introduction it had 261 pages with the addition of index.[1293]

On the title of the first page of Karl Andiran's book which he promoted, B.F. Erberg stated that Andrian has been his ancient professor of history. B.F. Erberg specialized mathematic in the class of Erasmus Frölich in Graz in 1741/42 and taught grammar there in 1743/44 in the time when Andrian taught history and sacred scripture as the dean of the philosophical faculty, confessor and leader of congregations in Graz from 1727/28 to 7. February 1745. In 1761/62[1294] the rector of Theresianum was Henricus Kerens appointed on 16. 5. 1760. Theodor Cronstein was his minister prefect of high school and professor of experimental physics. The relative of the deceased Karl Andrian, Anton Andrian (1731 Gorizia-1761 Vienna) was prefect of law as professor of Italian Language. Karl Taupe was prefect of law (Jur.) and Franciscus Gröding taught general and more Aristotelian approach which was still called as the particularly noted part of general physics (sic!). Izzo taught descriptive (Delin.) architecture as prefect of juridical studies. Johan Schöttl taught logic and metaphysics, Johan Baptist Fischer taught mathematics, and Sigismund count Hohenwart was a prefect.

Bernardin Erberg was a socius-librarian, a kind of assistant to the father Joseph Khell von Khellburg (1713 Linz-1772 Vienna) who served as the prefect of the library of Garell (Garelli) and the first confessor. Joseph Khell was a prefect of

[1294] Catalogus, 1762: 37-38.

library, but also a professor of history and numismatics, teacher of the Greek Language, confessor in the Jesuit house and the second confessor. Khell studied philosophy with Anton Kappler who studied philosophy-physics in Graz with Franc Dannhauser and mathematics with Jakob Urient who was a student of Ernst Vols. Khell was promoted by Erasmus Frölich and criticized Zanchi. In 1751, Khell published his widely used physics textbook entitled *Physica ex recentioris observationis accomodata usibus academicis* in Vienna which B.F. Erberg acquired for his lab in Ljubljana. Khell's textbook was praised even in Nova Acta Eruditorum in Leipzig in 1753 on pp. 360-362. It was reprinted in Vienna in 1754 and 1755.

By using the great Garelli's library and with the help of the Jesuit Joseph Hilarius von Eckhel (13. January 1737 Enzesfeld bei Baden in Austria unter der Enns-16. May 1798), Khell von Khellburg and his student Frölich advanced the numismatic into an academic discipline and published *Numismatica* in 1755; *Erasmi Frölichi ... numismata* 1751; *Epicrisis observationum Cl. Belley Academici Parisini in nummum Magniae Urbicae* also on numismatic in Vienna in 1767 with designs of the Abbé Augustin Belley's (1697-1771 Paris) Parisian book *Differentes pensées d'ornements arabesques*. Khell was a member of Academy Corton in Vienna.

Pius Nikolaus von Garelli (* 10th September 1675 Bologna; † 21st July 1739 Vienna) was the Viennese imperial physician and the husband of Maria Barbara Cäcilia von Schickh, the daughter of Georg Friedrich Ritter von Schickh who took care of Pragmatic Sanction. Garelli studied in Bologna and got his Ph.D. in medicine on 26. March 1695. Next year he came to Vienna. In 1703, he became one of the personal physicians of the future emperor Karl VI. Garelli became dean of Faculty of Medicine in 1703, and prefect of court library in 1723. In 1728 Garelli accompanied Karl VI to Trieste and examined newly exhibited Roman tombstones in Styria and Carinthia to bring them to the Viennese court library. In 1732, Garelli became the first imperial physician of the emperor Karl VI, but he was not so innovative as his descendant Gerhard van Swieten. Garelli collected valuable and expensive books and gave them with his testament to the court library, altogether 1932 works. B.F. Erberg certainly loved them all.

As the assistant librarian of Khell, B.F. Erberg had every reason to republish Andrian's work, especially as the glorification of the heritage of the empress Maria Therese. In his preface to the reprint of Andrian's masterpiece on pages I-X, B.F. Erberg described the merits of Karl Andrian and his published works (VII-XIII) including *Corollaria Curiosa ex Catoptrico-Dioptricis Principiis collecta & pro Academico Mathematico exerctio proposita*. Klagenfurt: Matthia Klerinmayr 1714 reprinted by Josef Kössler in Vienna by Kaliwoda in 1750, and by Maximilian Götzen (* 1723 Prague; SJ 1739 Vienna; † 1798), and Franz Xavier Staininger in Linz in 1759. Andrian's optics resembled Sebastian Stainer's exams in Ljubljana in 1714. Andrian anso published *Novissijma Carinthia Tabula Chorographica, Epocha Habsburgi-Austriaca...* with his student Ignaz count Atthemis (Ignaz Maria Maximilian Dismas Joseph Leander Attems (26. 2. 1714 Graz-17. 6. 1762 Vienna) who married Maria Josepha countess Khuen von Belasi zu Auer und Lichtenberg (* 4. 8. 1721 Hall by Innsbruck-1. 4. 1784 Vienna) in Vienna on 29. 10. 1739. Their book was published in Graz by Widmansatet in 1730 and reprinted in Vienna by Trattner in 1750.

In his 1762 reprint on pages XIV-XVIII B.F. Erberg added Index and a separate double page of the Habsburg Genealogy with additions of Maria Theresia offspring born or died after Andrian passed away in February 1762 including the daughter of Josef II Theresia Elisabeth (* 20 March 1762–23 January 1770) which indicated that B.F. Erberg prepared the work late in 1762. After that, Andrian's own historical work was printed up to page 281. Index of persons on the end provided just Habsburgs, and not for example, the emperor Sigmund of Luxemburg or his wife Barbara.

6.10.4.6 Trnava Ministry and Prefecture

In between his two terms in Theresianum, B.F. Erberg left for the Hungarian part of Habsburg monarchy to serve as minister, prefect of temple and confessor in Slovakian Trnava in 1765-1766. The clouds already gathered over the Iberian and French Jesuits of those times when even the Roman Jesuits were far from popular. Despite of those failures, the positions of Jesuits in Habsburg areas still looked like fine and nobody really expected the final Viennese blow.

B.F. Erberg's rector in Trnava was Nicolaus Schmitth appointed on 15. 10. 1764. In 1763-1765 in Trnava, the professor of mathematics was the Hungarian catechist Anton Jarányi (Jaránui, 1725 Pécs -1797 Pécs), and Johannes Baptist Schwelmer (1728 Banska Bystrica-1775) replaced him in 1766-1767. In 1765 the Slovakian Anton Muszka (1719-1790) headed the local library after he published his *Heroes Daciae* in 1744 and taught some physics in Košice. Johannes Gottgeisl taught physics while Johannes Mólnar taught logic and metaphysics and Josef Führer headed the specialization in applied mathematics. Michael Horváth was an adjunct to the prefect of astronomical observatory Franz Weiss.[1295] In 1765/66 Janos de Tordas Kaloz Sajnovics (Sainiovics, 1733 Tordas-1784 Pest) became new Weiss' assistant and accompanied their friend Maximilian Hell to Laplandic Venus's transit journey. Under prevailing Venus' influences which are always dangerous for the priests Sajnovics suddenly turned into a kind of compared linguist in the Jesuit traditional manner of a polyglot.

Weiss' astronomical measurements and his assistants were among the best worldwide, but B.F. Erberg was never very impressed with astronomy like his first cousin once removed Augustin Hallerstein in Beijing.

6.10.4.7 Ljubljana Returns

In 1771/72, B.F. Erberg returned to Ljubljana college for his very last time. His family was glad to offer to him a devoted book of Liborio Siniscalchi (1674-1743) *La scienza della salute eterna: ovvero Esercizi spirituali di S. Ignazio* printed in Venezia by Tommaso Bettinelli in 1755. The book was leather-bound with red stained edges and gilded front and back covers and spine. There was the coat of arms of the barons Erberg on the front and back covers with the motto "Non est mortale quod opto", and black propriety entry of the Barons of Erberg on title page.

In Ljubljana, B.F. Erberg was minister of his old friend the rector physicist Karl Dillherr (1710 Vienna-1778 Stein by Krems) appointed on 26. 4. 1768, prefect of church and temple, as well as the confessor. Liker B.F. Erberg, Dillherr promoted many books but more vehemently concentrated on somewhat obsolete Kircher-Linus filled vacuum and Tycho's astronomy. On confessions, B.F. Erberg discovered the great talents of otherwise poor farmer's son Jurij Vega and told his professors Bernardin count Hohenwart on the chair of logic-metaphysic, head of seminary Moraučer, G. Gruber, Michael Schmid and after him Maffei on the chair of mathematics, prefects of lower and higher schools Innocent baron Taufferer and Ignaz Rasp, professor of moral theology former mathematician Ignaz Rosenbeger, G. Schöttl, and his own first cousin once removed the librarian Joseph Erberg (Catalogus 1772: 16): "We have an extraordinary guy here! His mathematics is more than excellent. Please, take care for him, not just because he was born near our castle of Dol, but also because he is a real genius!"

6.10.4.8 Last Stops in Krems by Danube: Erberg's Great Influence on Jurij Vega and their Other Talented Neighbors Born Near Dol Manor

B.F. Erberg headed the seminary as the prefect of musical college chorus in Krems in 1768-1771. He liked the nice small peaceful city and returned there in 1773 to pass his last days just like his friend Dillherr did few years later in somewhat strengthened circumstances with their Jesuit order no longer in power. In 1768 in Krems, B.F. Erberg's rector was Johan Nepomuk Bottoni (1707-1790 Krems) appointed on 23. 2. 1766[1296] Bottoni used to teach physics in Ljubljana in 1744/46, therefore he and B.F. Erberg shared many friends and memories. There were no mathematical and physics lectures in Krems, but the folks had fun anyway. The lyrical Jesuit poet Lorenz Leopold Haschka (Haska, 1749 Vienna-1827 Vienna) studied in Krems with B.F. Erberg and became a Jesuit in 1764. Haschka specialized languages and applied mathematics in Graz and returned to Krems as the lecturer of grammar to help his teacher B.F. Erberg in his last days.

Four months B.F. Erberg's younger acquaintance Martin Johann Schmidt (Kremser Schmidt, 25 September 1718 Grafenwörth of Lower Austria east of Krems on the way to Vienna-1801 Stein-

[1295] Catalogus, 1765: 29-30.

[1296] Catalogus 1768: 8.

sur-Danube) became the very leading Habsburg painter draughtsman, etcher and engraver of late Baroque and late Rococo. Kremser Schmidt worked in Ljubljana for G. Gruber. In 1756, Kremser Schmidt settled in the centre of the local white wine production called Krems joined by Stein east of Vienna and worked there sometimes in B.F. Erberg's company in the Jesuit college established in 1616 until his very end. The Capuchins established their monastery nicknamed Und between Stein and Krems six years before the Jesuits in 1612.

The barons Erberg were closely associated with the Jesuit College of Ljubljana. Everybody studied there and many used to teach. At the time of the Vega study, first cousin once removed of B.F. Erberg. Volbenk Daniel Erberg (* 1713; † 1783), was the owner of Dol manor and the library, which was in his Ljubljana Baroque palace on Mestni trg no. 17 (then Ljubljana No. 237) until 1810. The building was renovated in 1748 and 1758.[1297] With the recommendation of his school confessor B.F. Erberg Jurij Vega could use the local library of his lord Volbenk Daniel Erberg, where he examined primarily Schooten's table of angular functions and Wolff's logarithms. Bernardin Ferdinand Erberg had a strong influence on the young Vega. He certainly also gave him a kind of support suitable for the poor people.

The 17-year-old student baron Jožef Kalasanc Erberg (1784-1793) met the captain and professor Vega in high circles when Vega returned for a short time to his teaching of mathematics in Vienna in 1793. Of course, this was no longer a meeting of a superior landowner baron Erberg with his subject, as Vega soon climbed up to baron's title too. In his Experiment of Carniolan Literary History, Jožef Kalasanc Erberg mentioned four times Jurij Vega and classified his mathematical works as a classic. Twice he emphasized that Vega was born in Zagorica above the Sava river. In the Vega age, before the independence of the Dol parish at the end of the 18th century, the Zagorica was not part of the parish Dol but of Moravče parish.[1298]

Vega was not the only successful Erberg's student from the immediate vicinity of their Dol manor. In 1749, Franc Anton Završnik (Saverschnigg) from Moravče bound Johann Baptist Klauber's (1712 Augsburg-1787) engraving of St. Norbert (Gennep, c. 1075 Xanten-Magdeburg–1134) and dedicated it to the count Kajetan Wildenstein (Josef August, 1703 Styria-January 6, 1764 Ljubljana) of the German Knight Order in Ljubljana in 1738-1761. Six years after France in 1755? his neighbor Martin Dettela (Detela) from a well-known Moravče family completed his studies in Ljubljana. He had bind to his exam questions Salomon's anointing etched by Philip Andreas Killian (* 1714 Augsburg; † 1759 Augsburg) by the painting of Gerard de Lairesse (1641 Liège–1711 Amsterdam) of 1668. Martin dedicated the etching and examination thesis to the uncle of Jožef Kalasanc, then local Moravče parish priest Ferdinand Benedict Gabrijel Erberg,[1299] who quickly found the necessary coins for printing. Martin became priest after his first tonsure on April 10, 1751. Jožef Kalasanc obtained a collection of the examinations of the two Moravče natives from his uncle's legacy, as they were usually shared with the audience at the public examinations in Ljubljana. Jožef Kalasanc Erberg kept copies of both examination theses of his Moravče neighbors in his Dol library. Jožef Kalasanc Erberg specifically mentioned them in his experiment in Carniolan literary history.

6.10.4.9 Erberg's Manuscript of Physics (Physiology)

In Archive of Republic Slovenia under the reference code AS 1073 (manuscript 242 r), 129 leaves with bound book of half A4 format are stored as a continuation of the first 15 leaves with notes of the manuscript 178r. Every other page of the text is paginated. Therefore, we will mark the left side with "a", and the right with "b". The title page is "Erberg: Physics". The text is German in Gothic script. Therefore, it is assumed that manuscript was not produced at the college in Ljubljana, where the German language dislodged Latin language barely in the mid-eighties. In Vienna and Graz, the German language has already become established in science. The manuscript has a seal of Erberg's library. In the index and on the cover, Erberg is listed as the author. Manuscript is not dated. The next manuscript in the Archives of the Republic of Slovenia AS 1073 (143 r = 243r) has a year of 1744. Around this year, the author of

[1297] Kidrič, 1926, 163; Prelovšek, 1984, 184-185.
[1298] Uršič, 1975, 80, 96, 121, 252; Jemec, 2008, 383.
[1299] Uršič, 1975, 148; Kidrič, 1926, 161.

the manuscript could have been Bernardin Ferdinand Erberg, who could write it during his studies in Vienna from 1739/40 until 1740/41 and later took the item with him to the college in Ljubljana. The author can also be his older first cousin Anton, or Jožef Kalasanc Erberg much later.

In his student manuscript of physics, Erberg described the physiology of man. He discussed in parallel the physics issues of heat in the body and the light in the eye. Therefore, the later title "Physics" is incorrect from the modern point of view, the more appropriate would be: "Physiology". He added a lot of physics and chemistry to the treatment of air pressure (1, 48), vacuum (2a), vacuum pumps (15a), phlogiston theory (8b-11b) with Adair Crawford (1748 - July 29, 1795) noted as Craford (44b), a camera obscura (58), an eye (60a), a short-sightedness (63b), an acoustics (13b, 17b, 19a), planets (21b), arteries and veins (27a) and concave lens optics (64). According to the notes about Crawford, probably focusing on German translation of Crawford's works of 1785 or 1789, the item may have been used for the student notes of Jožef Kalasanc Erberg (* 1771) from 1789 or 1790. J.K. Erberg completed his third year of gymnasium in Vienna in 1784 and finished his studies in logic in 1788. In 1789, he attended the lectures of mathematics of the professor Metzburg. A year later, J.K. Erberg studied philosophy, perhaps with Ambschell. In 1791, J.K. Erberg studied the National law, and in 1792 the Civil and German State Law. Such notes may have been illustrated by Ambschell's lectures.

The text was subsequently numbered on every second page. The first fourteen sections of the manuscript were not preserved. Thus, the manuscript is now starting with the fifteenth paragraph on air and air pressure. He then considered the vacuum and the problem of fear of vacuum nicknamed horror vacui. These questions were extremely popular one hundred years ago when Torricelli discovered the barometer and explained its operation with air pressure. In Erberg's time, the air pressure already completely displaced older Aristotle's ideas.

The text continued with the description of arteries, lungs, and the circulation of air in the blood. The oxidation which behaved like burning air in veins, blood and lungs[1300] was described by the theory of phlogiston and its elimination from the air.[1301]

The phlogiston theory was developed at the beginning of the century by the German chemist and physician George Ernst Stahl. It was used up to Lavoisier's burning experiments and calorie theory in the 1770s. The Zagreb professor Josip Franjo Domin argued for the phlogiston theory in 1784,[1302] Kant in 1787,[1303] J. Priestley and others even later.

In the following, Erberg wrote about sounds, musical instruments and tone modulation. He switched from acoustics to physiology and discussed emotions, odor, hearing, and elasticity of the air and other bodies.[1304] He dealt with light and vision in detail. He illustrated his eye with the camera obscura, which B.F. Erberg acquired in 1755 for the new cabinet of the Ljubljana College. In a modern way the author of the manuscript described short-sightedness, other eye defects and types of lenses. He wrote some interesting physics, especially concerning the theory of phlogiston.

7 First Major Industrial Uses of Vacuum and Overpressure Technologies: Steam Engines

7.1 Steam Engines - Introduction

Erberg family promoted the new knowledge and technologies including steam engines in Carniola and nearby. In the 18th century, the designers of steam engines used vacuum technology for the first time in industry. The development of steam engines therefore moved from the scientific laboratories of educators to workshops of gifted self-taught inventors. The development of technology has been a forerunner of science for decades. Thus, the first serious theory of the steam engine's operation was only published by Carnot at a time when steam engines were already widely used in developed parts of Europe. In many other examples the scientific theoretical explanation might figure as the forerunner of industrial technological (mis)use like in the cases of lasers or atomic bombs, but in the development of steam engines the relation between both parties were clearly turned in opposite directions.

7.2 Vacuum Technology in a Steam Engine

The peg-top propelled by steam jets nicknamed aeolipile was among the best Heron's designs around 50 AC in Alexandria in today's Egypt. Heron's more practical approach relied on earlier designs of Ctesibius (Ktesibios, Tesibius, 285–222 BC) and Vitruvius (c. 80 BC – c. 15 AD). Heron's appealing idea was improved by Blasco de Garay in 1543, Solomon de Caus in 1615, the Italian Giovani Branca in 1629, the Marquis de Worchester in 1663 and by the Sir Samuel Moreland in 1682. Huygens's research of those overpressures in newly created AR program was presented to the almighty minister Colbert in 1666. Huygens intertwined by almost the same breath the pioneering research on the vacuum pump and the driving force of the water vapor. He therefore combined overpressures and lowered pressured with nearly the same technique. His assistants Leibnitz and Papin endorsed the same approach to become the most famous among men who developed both vacuum pumps and steam engines. The invention of cooking under high pressure enabled Papin's election to the RS in 1680. Papin's may well have been obtained that excellent idea during his service to Boyle, who in the 1660s had boiled water at the lower temperatures under pressure below 1/30 bar. Between 1690 and 1695 in Marburg Papin compiled the first usable steam engine with a piston, which have lifted even 27 kg. In 1698, he improved his steam engines in Germany and Italy, but neither RS nor other wealthy patrons supported his plans. Today, it is surprising that Papin did not use a special boiler in his device, but instead contributed to the role of the boiler as a cylinder, from which he had to pull in or out of the piston at every engine cycle. Such design was relatively unusual in Papin's time also because Papin did not have the necessary craftsman's experience.[1305] In correspondence with Leibniz he made a well-known steamboat, but the authorities in Fulda destroyed it because he did not pay the required fees. The politicians have always worked hard against great scientists and have taken care of today's and not for future glory. According to other sources, Papin made a normal ship without a steam drive which angered the local fisherman. In any case, the gullible Papin invested all his possessions in the ship, so he was devastated after confiscation because he planned to sail to England to impress the queen Anne in September 1707.

The Englishman Savery from Devonshire used Papin's idea and the results of Boyle and Guericke's vacuum research. Savery's Friends of Miners with 500 horsepower were mainly used to pump water from the mines. In 1698, Savery obtained a patent for his device and accepted his neighbor a blacksmith Newcomen from Devonshire as a partner. The following year Savery presented his working model to the RS fellows, where it was certainly rated by Hooke. The sketch was published in Phil. Trans. with Savery's notes, and Savery was elected as a new fellow of the RS. Savery was certainly wealthy enough to pay the RS fees. Unlike his predecessors, he did not hide anything mysterious as he published a detailed description of his device to get the RS monopoly on fire powered engines while Papin and Leibniz criticized his claims as a part of Newtonian propaganda against Leibniz' networks.

[1305] Sittauer, 1989, 7, 9; Bogoljubov, 1984, 209; Frankfourt, 1976, 155; Asimov, 144–145; Dickinson, Vowles, 1945, 21.

Newcomen had already corresponded with Hooke about the atmospheric engine and Papin's device in the 1680s. As the old fan of the voids, Hooke advised the use of a vacuum under a piston, which would allow the atmospheric pump to function successfully.[1306] In 1712, Newcomen assembled a device that did not use steam at high pressure, but the work was carried out at the normal air pressure. The pistons and cylinders must therefore be very well sealed, which was later the basic idea of Vega's improved mortars. Newcomen's steam engine remained in general advanced use from 1725 to Watt's improvements, although Newcomen's designs were far too heavy for anything portable. In 1711 and 1712 the similar devices were built by Newcomen's partner the Englishman John Cawley (Calley, 1663 – May 1725 The Hague), followed by Swedish inventor Christopher von Polhem. However, the craftsmen of their time were not yet able to put together vessels that would work safely under vigorous vapor. John Kay in 1733, John Wayatt, Lewis Paul, James Hargreaves in 1764, and Arkwright with a spinning machine in 1769 enabled the use of steam engines in the textile industry.

The Scotsman Watt first used the second container as a condenser in Newcomen's machine in 1769. This avoided the losses of older models where at each cycle steam had to heat up again the water, which already participated in the previous cycle. This increased the speed of the piston movement, which did not exceed 20 liftings per minute before Watt.[1307] After Watt's improvement, it was no longer necessary to wait for the heating of the container. Watt's steam was pushed by a poston alternatively from both sides, which was not possible with Newcomen's design. Watt's products were much lighter and able to transform the linear motion into the rotations needed for steamers.

In 1756, Black was named Professor of Chemistry at the University of Glasgow when Watt was set up there as a "maker of mechanical devices".[1308] After the initial Black's support, which was not black at all, Watt joined the English businessmen and began to produce steam engines for the market in 1774. In 1781, he composed leverage with which the movement in one direction could rotate the wheel. The invention has opened new areas for the use of the steam engine, first in the iron industry. Until 1790, Watt's products completely replaced Newcomen's engines and started to be used in France. In 1800, the English used already 500 Watt's steam engines. Carnot published the theory of steam engine operation in 1824. Carnot's book was too technical for physics and too mathematical for technologists; so, it was correctly assessed only by the next generation. He used the wrong measurement of Delaroche and Bérard's dependence of the specific heat of the air on the pressure issued in 1812. He expanded his results to the pressure range between 1/1024 and 1024 bar and tabulated the results. In the following, he assumed that air at a pressure of 1000 bar reached the density of water and was liquefied, with the last claim being incorrect.[1309] The highest pressures from Carnot's table were achieved only by the physician Johann August Natterer in Vienna in 1844, and the lowest pressures from Carnot's table were achieved only by Töpler at the University of Jena eighteen years later.

7.3 Steam Engines in Carniola

In 1596, the first notes about the power of steam appeared in Ljubljana notes of Gregor Corissa on the fireball of Joachim Turekh. A century later soon after the establishment of Ljubljana Higher studies on October 4, 1705, Zaharias Greyl (Greil), a citizen and a copper dealer from Augsburg, described his research of the fire of steam engine in Ljubljana. It was made of copper and worked circularly according to the unnamed English model, probably designed by Papin's modification of Savery's engine to lift water onto a water wheel for rotary power. Greyl stated that his device could be used for rarefaction (of air) and for the propelling of ships. A similar device has been used in Upper Carniola (Gorenjska) already for three years. On July 27, 1717, Greyl asked the Carniolan provincial States general and emperor for financial support amounting 1000 ducats. The illustration scheme was attached to his file.[1310] Greyl's Ljubljana projects were parts of his broader efforts in Holy Roman Empire. In 1716 in Augsburg Zaharias Greil made successful attempts with a barrel filled with water which was scattered to all sides like the finest dust or a vapor blown up by powder. In 1718 the same silver engraver from

Augsburg Zacharias Greil (Greyl) invented and designed his fire extinguisher for cooking. He promoted his novelty in Augsburg, Vienna, Regensburg, Dresden and Paris. The so-called Greylsche extinguisher, which Zacharias Greyl invented in Augsburg; through them a fire can swiftly evaporate smaller quantities of water with a help of several men. The machine has the wooden vessel of the dimension 10 x 20 inches. The openings were sealed with wooden screws. The cylindric rifle made of lead (bleicherne cylindrisch Büchse) with diameter of 3 inches and height of 9 inches was used as the heater with powder. The third part of design was the machine of small vehicle with long shaft. The city of Augsburg granted the official patent (Copia Attestati) to Greyl for his newly invented swift fire extinguishing machine for cooking with extinguishing bomb (Löschbombe) on 16. 4. 1720 and 30. 10. 1720. On 5. 8. 1721, aspirations of the widow of Greyl named Elisabeth were altogether successful, because of the previous demonstration of the extinguishing bomb as the attestation of the advice of the city of Augsburg.[1311]

A century after Greyl's proposals, the first steamer on the Slovene ethnic territory was tested in Trieste in 1818, where the Bohemian German Ressel performed his experiments with a screw in 1829. In 1835 they set up the first steam engine in Carniola in the Ljubljana house named Cukrarna (Sugar-Factory). Five years later, the first steamer was rounded up along the Ljubljanica River by a power of 14 hp.

Due to the good administration and efforts of the Auersperg princes, the grandchildren of the first Carniolan vacuum researcher, Janez Vajkard Auersperg, their Kočevje manor was one of the most advanced industrial centers in Carniola in 19th century. In 1840, Pugster set up a steam engine in the Gottscheer Glassworks (Kočevska Glažuta), where the Auersperg family was running a glassware factory from 1837 to 1852. In 1870/71 a steam powered saw was placed there. In 1844, the first steam sawmill in Carniola and the other Slovenian territory was placed on the premises of today's bus station in Kočevje. Its power was 20 hp. Just before the March Revolution, Auerspergs began to place steam engines in their Ironworks in Dvor. Thus, they took advantage of the vacuum technique that the first prince of their genus helped to establish two centuries earlier. Janez Vajkard Auersperg's pioneering spirit helped his heiress to develop the domestic vacuum of steam engines. Later, their Ironworks in Dvor were closed because their Slovenian political antagonists put the tracks of the railway as far from Dvor as possible.

7.4 The First Steam Engines Discussed in Print among Slovenes

Steam engines were the first serious testing of the usefulness of the new vacuum technology, although the essential area of the steam engine is naturally overpressure. De Maillard's steam engines attracted among the first the attention of the people of Ljubljana. In 1783, De Maillard received the Petersburg Academy Award for his description of steam engines in the French language. In 1784, his book was reprinted. In the year 1800 de Maillard was a correspondent member of the Petersburg Academy, and in 1817 he published a book on navigable canals. In 1783 as a lieutenant colonel he was the director of hydraulic works in the monarchy, where he replaced the professor of Ljubljana Gabriel Gruber, who until then had been the director of all hydraulic works on the Habsburg rivers, except the Danube. Thus, Gruber acquired De Maillard's books for the Ljubljana Higher Education Library.

De Maillard (* 1746; † 1822) of French origin served in the Habsburg army. In 1784, he was the Habsburg Captainlieutenant; together with artilleryman Jurij Vega in 1789 he participated in battles for Belgrade and then in battles against the French. So, in 1800 De Maillard became a colonel of imperial units. He began the introduction of his book with a description of the history of steam engines of Savery and Papin. He believed that the

[1311] *Copia Attestati, Welches von Einer Wohl - Löblichen Reichs - Stadt Augsburg, Zachariä Greyl, Bürgern allda, einer neuinventirten geschwinden Feuer - löschenden Maschine halber, ertheilet worden*. 1720; Johann Heinrich Moritz von Poppe. 1804. *Encyclopädie des gesammten Maschinenwesens, oder vollständiger Unterricht in der praktischen Mechanik und Maschinenlehre: mit Erklärungen der dazu gehörigen Kunstwörter in alphabetischer Ordnung : ein Handbuch für Kameralisten, Baumeister, Mechaniker, Fabrikanten und Jeden, dem Kenntnisse der Maschinen nöthig und nützlich sind.* Volume 2. Leipzig: Georg Voß, 202-203; Alexander Jürgen Flechsig, 2013, *Frühneuzeitlicher Erfindungsschutz: eine Untersuchung unter besonderer Berücksichtigung der Reichsstadt Augsburg*, Münster: LIT, 129-131.

Englishmen were the first to build steam engines, but only a few were designed in other parts of Europe. He did not even mention the Habsburg monarchy, which apparently lagged somewhat behind. Certainly, De Maillard did not know much about the eastern origins of his steam engine like Badīʿ az-Zaman Abū l-ʿIzz ibn Ismāʿīl ibn ar-Razāz al-Jazarī’s (بديع الزمان أَبُو اَلْعِزِ بْنُ إسْماعِيلِ بْنُ الرِّزاز الجزري, Jazari, 1136 Mesopotamia–1206 Mosul) double-action suction pump with valves and reciprocating piston motion of 1206, rotating spit steam engine of the Istanbul inventor Taqi al-Din Muhammad ibn Ma'ruf ash-Shami al-Asadi (تقي الدين محمد بن معروف الشامي, Takiyüddin, Taki, 1526 Damascus–1585 Istanbul) designed in 1551 or Tiangong Kaiwu’s (1587-1666 AD) Exploitation of the Works of Nature as a Chinese encyclopedia of Song Yingxing (宋應星, 宋应星, Sung Ying-Hsing) with various gunpowder weapons and tools published in May 1637 as the technological extension of Song Yingxing’s dichotomies between the solid *xing* (形) and living energy *qi* with fire intermediary between those two forms.

In the first part of the book De Maillard described a steam engine. In the second part De Maillard discussed the theory of the steam engine, the piston and the pump. He calculated the efficiency of the devices and described the performance of the machine in Bois-bossu near S. Guislain in Habsburgian Haynault (Hainaut) as one of two areas that form the eastern area of département du Nord while the western part is today in Belgium). It has a diameter 30.5 "pouces" (75 cm) with a 6-foot pistol (2 m) and 32 cubic feet of emptied workspace. The first French steam engine designed by T. Newcomen’s inventions in the city of Fresnes now in southern-southwestern suburbs of Paris was capable of 15 revolutions per minute in 1735; for that times, it was an enviable speed.

In the third part of the book, De Maillard offered his theory of modern devices propelled by the fire. Savery and Newcomen’s machines have already undergone many changes. One of the basic problems was to prevent the cooling of cylinder. De Maillard did not mention the improvements of the Scotsman James Watt. As early as 1769, Watt's invention surpassed the efficiency of Newcomen's machines and completely replaced them by 1790. Of course, in the Habsburg monarchy the local experts had somewhat delayed the news of Watt’s success.

De Maillard calculated the maximum efficiency and increased the pressure of twice greater amount of steam at the same volume. Of course, he did not know the later Carnot's ideal steam engine, and he published numerous copper plates for steam engines used as weightlifting machines mostly in mines. According to Maillard, Friderich Franz Edler von Entressfeld (Entersfeld) from Vienna designed the steamer with the working title Maschinenschiffes, which was tested by the professor Gabriel Gruber in at least two versions in nature in Mura river by Graz. The Styrian agricultural society supported the plan as Entressfeld was its member. From the reports of Graz Gubernia, we can see that Gruber first put in place a wooden bearing model reported to Emperor Joseph II on 7. 12. 1779;[1312] his mother Maria Theresa died shortly afterwards and did not trouble herself with such headaches. On Mura by Graz Gruber tested a new type of vessel named the machine ship and it was probably equipped with a steam engine; of course, not a heavy Newcomen’s machine, but rather with Watt's design. The prevalence of sailboats was already damaged, even though "the opponents" with their noisy steam did not go smoothly towards their inevitable success, especially when Karolina steamer sunk in the Drava river in 1821.[1313]

It cannot be proved that Gabriel (Gabrijel) Gruber used any steam engines during the construction of the Gruber’s Ljubljanica river canal, although he had to draw water during his workers’ excavation and digging. Gabrijel Gruber used new vacuum technologies among the first in continental Europe, and with Gabriel Gruber younger brother Tobias rejected Darwin's assumption about the mechanical expansion of gas from a steam-powered miners’ pump, which supposedly took heat away from the body of a valve in the Slovakian Banská Štiavnica. T. Gruber ensured his readers that the dilution of liquid caloric only affects the bodies nearby, as denser air does not emit heat to the surrounding area. Three years earlier he used his own measurements of the dependence of the boiling point of water on external pressure,[1314] his own

research of the charged clouds as thermal insulators was published in 1790.[1315] With the assumption of cold high parts of the atmosphere, T. Gruber explained the formation of a hail in an allegedly similar tides of the atmosphere, as seen in the oceans. Certainly, the global-scale periodic oscillations of atmosphere analogous to the seas were studies only after Torricellian experiments as the peculiar feature of these atmospheric surface pressure tides makes them primarily solar semidiurnal. Laplace concluded that the solar dominance implied their thermal origin.

8 Pioneering Vacuum Electronics: Low-Pressure Glow Discharge Tube

8.1 The Rapid Progress of Vacuum Technology in the Second Half of the 19th Century

8.1.1 Stagnation in the Development of Vacuum Technology by the Middle of the 19th Century

The steam engines used vacuum techniliogy and provided new hints. Because of the long delay in the efforts to achieve the best possible vacuum, after the invention Hauksbee's pump was on sale for a half a century without major changes. In 1850, at the Great Exhibition in London, the first prize was given to Jeremiah's son Francis Watkins (1800-1847) and William Hill's (before 1780-1847) pumps with a double tube, an oiled silk valve and conical pistons. It reached a pressure of 1.3 mbar, which was only six times better than two centuries earlier Boyle's achievements. Otherwise, mercury pressure gauges then measured only down to 0.7 mbar. F. Watkins's wife corresponded with Nicéphore Niépce while his granduncle collaborated with John Dollond. The next year, at the large exhibition in London in the international competition, the pump of Englishman John Frederick Newman (1783 South Londoner Peckham, Surrey-1860 borough in Northwest London of Camden, Middliesex) won with its operations still based on Guericke's invention.[1316] The gatherings at major international exhibitions have expanded improvements in vacuum technology at the meetings of inventors and users since the mid-19th century. A meeting at a similar exhibition half a century ago led to the establishment of the International Organization of Vacuum researchers. Some international exhibitions received the adjective "electrical" in the 1880s. For the Slovenian networks, the Electrical Exhibition in Vienna in 1883 was of greatest importance, also because the Slovenian Jožef Stefan headed it on the technical and scientific side. That same year he became the president of the Electrotechnical Society in Vienna, which

Figure 8-1: Thomas Andrews(* 1813; † 1885)

was founded after the example of a three-year-older society in Berlin. It also joined the vacuum researchers. In 1852, the chemistry professor at Queen's College in Belfast, Thomas Andrews, found that Torricelli's vacuum over the mercury column in the barometer was still better than a vacuum accessible through pumps, as it only contained mercury vapors. Only few of the current pumps reached 3.3 mbar. However, only a few physical experiments could be carried out in Torricelli's vacuum, such as the drop-in dust in a vacuum or the dissemination of the air in a closed balloon, which the Florentine academics set up in a vacuum. Torricelli's vacuum is a result of single extraction of small volumes, which is relatively cumbersome.[1317] That is why researchers preferred to pump the vacuum, which Andrews still improved with getters. In 1850, a crystallographer Schröter von Kristelli as a professor of chemistry at the Polytechnic and the Secretary General of the Viennese Academy visited Postojna Cave and an Idrija mine. In Idrija of those times the miners dug up most of the mercury for barometers, so Andrews got ideas for exploring low pressures (Figure 8-1).[1318] In 1861 Andrews began to explore

1318 Andrews, 1889, XXIV, 223–224.

high pressures. He tried to liquefy gases, which were considered "permanent" until then, and began a long-term match to achieve an absolute temperature zero.

Also, Schröter began his research of vacuum after meeting Andrews and testing the early version of Geissler's cathode ray tube. He experimented with a phosphorus steam in a tube, 30 cm long and 2 cm wide, and with the other 40 cm long and 1 mm wide. The distance between the electrodes was 26 cm. After discharging, "the walls were covered with brown-red to gold-yellow thin layer of amorphous phosphorus, which reminded of the colors of thin bodies". He additionally repeated Hittorf's experiments from the year 1865.[1319]

In 1859, the Parisian engineer Giffard used the principle of dynamic pressure in his syringe or pump on water jets after he demonstrated manned airship powered with a steam engine in Paris. At the same time, Schimper assembled the blower pump, which quickly became established under various names, including as a "sputtering" pump.

8.1.2 *Use of Vacuum in Cathode Ray Tube*

8.1.2.1 Geissler: the First Usable Cathode Ray Tubes

The vacuum used in steam engines was outside the dominant direction of research in physics in the century between 1760 and 1860. New discoveries at the beginning of the second half of the 19th century re-invigorated the research of vacuum. In the second half of the 19th century, the vacuum was improved in three ways: better sealing in completely glassy systems without rubber and other parts, heat treatment of the glass to remove adsorbed gases, and improved pumps with a liquid piston. More powerful batteries enabled the observation of discharges in a vacuum that inspired Davy and Petrov's attention already in the early 19th century. Davy's battery with 2000 pairs of Zn-Cu elements occupied the space of a huge hall, and Petrov used 100 more pairs at a voltage of around 1700 V. Petrov changed the substance, shape and distance between the electrodes and the pressure in the cathode ray tube. In 1804, he reported from the Petersburg Medical Academy department of surgery: "When we continue pumping air from the bell and perform five movements of the piston, we see the light in several parts of the bell and in the whole oil delivery device. Lighting is even more pronounced when pumping down to 2 1/2 lines of the ordinary mercury barometer. In subsequent pumping, the shine becomes weaker and ultimately invisible."[1320]

With the support of relatives **Vasilij Vladimirovich Petrov** from Oboyan (Обоя́нь) in the Kursk gubernia graduated from the Collegium in Kharkov in 1785. Three years later he finished a teaching seminar in St. Petersburg. He was employed as a teacher of physics and mathematics at the Kolyvan-Voskresensk (Колывань-Воскресе́нск) mining school in the Siberian city of Barnaul (Барнаул) which was established in 1753. In 1791 he started teaching in the more promising St. Petersburg, and two years later he moved to the Medical Academy of Surgery for the next forty years. In November 1802 he assembled a battery with 2100 Cu-Zn elements and a voltage of about 1700 V. With he obtained the first operative carbon arc-lamp. Between 1810 and 1827, he also led the Physics Cabinet of the Petersburg Academy, and in 1807 he became a full member of the prestigious Petersburg Academy. However, his works published mostly in Russian language were used by Westerners only half of a century after he passed away).

Davy's work was continued by his student Faraday although there might have been some misunderstanding among those two self-taught experimental geniuses. In 1848 Plücker visited Faraday in London and then proceeded where Faraday stayed due to illness. They collaborated closely, as they used the experimental devices of Englishman Gassiot in Bonn and Münster, and important publications were regularly translated on both sides of the English Channel.[1321]

With sufficiently high voltage, further progress in the research of the glow discharges required a better vacuum. In 1854, Plücker commissioned his friend Geissler to produce a better glass air pump for exploring discharges in a diluted atmosphere. Right then, Geissler opened a workshop for

[1319] Geissler, 1874, 171–173.

[1321] Hittorf, 1869, 5, 202.

scientific instruments in Bonn, which was at the same time a ten-store workroom and a shop. He perfected the old Swedenborg’s idea. In the decades following Guericke's and Auersperg's Regensburg experiments, kings still had a decisive role in promoting experiments. Therefore, a member of the Swedish Royal Academy of Sciences Swedenborg (Figure 8-2) first showed his new hydraulic vacuum pump to his king Charles II.

Heinrich Geissler from Igelshieb in Thuringia had a glass workshop at the University of Bonn and then he headed it in the Netherlands for another eight years. In 1854 he returned to Bonn and later joined his workshop with Franz Müller’s firm. Geissler's brother was a famous mechanic who made meteorological and other devices in Berlin. H. Geissler began his scientific work with the measurements of the coefficients of linear temperature expansion of materials which he used for a thermometer in which the expansion of mercury and the glass were compensated by one another (Plücker, Geissler, 1852, 238-279). In 1853, he set up a CO_2 extraction apparatus. In 1862 he became the honorary doctor at the University of Bonn. He then compiled a maximum mercury thermometer, modeled on Cassel’s devices in London and different from Negreti and Zambi’s tools. Geissler's maximum thermometer was presented to the Berlin Academy by Heinrich Wilhelm Dove. Dove was born in 1803 in Liegnitz and served as a professor at the University of Königsberg (today's Kaliningrad) and later in Berlin. In 1868 Geissler described the light flashed in the cathode ray tubes and in the mercury vacuum of Torricellian tube, which he rubbed with the cat's hair. The lightning lasted for one minute, and its color was dependent on the temperature and on the nature of the gas in the tube. He advised the use of the Davy lamps. He was not yet able to connect his observations with the then known luminescence phenomena. Six years later he published a discussion on the conversion of phosphorus into an amorphous form in the cathode ray tube. Somewhat later, the researchers versed in luminescence and cathode ray tube lightning phenomena finally noticed their resemblances.

Swedenborg used a table with two tall legs holding a closed bell. He connected the steel vessel to the steel tube through which the mercury streamed. Instead of a solid piston, Geissler also used mercury in a glass tube, and reached the lowest pressure of 0.1 mbar in 1857. His design was in fact the multiply repeated Torricelli’s experiment.[1322] In the first months of 1857, the Geissler’s inventions were tested in Plücker's Cabinet of physics in Bonn, where the assistant Wilhelm Heinrich Theodor Meyer (Ludwig Christian Karl Mayer, * February 8, 1820/1825 Michelbach part of Marburg in Hesse (Nassau)) studied the stratification of electric light in September 1857. Geissler also sent one of his cathode ray tube to his brother Friderich Wilhelm Geissler in Amsterdam. Plücker presented the invention to the Rhine Society of Naturalists and physicians, and later to the Society of German Natural History scientists and physicians. In the first two cathode ray tubes which Geissler supplied by the order, the vacuum contained mainly mercury vapor and atmospheric air, but less essential oils, hydrogen and phosphorus. He used electrodes made from platinum. Plücker immediately coined the term "Geissler tube"[1323] while the device was described in more detail only by Plücker's assistant W.H. Theodor Meyer next year in Berlin.[1324] On September 9, 1857, a report was published in the Kölnischen Zeitung. Meyer’s dissertation was not completed in Bonn but in his native Marburg in August-November 1857. On 21 September 1857 Meyer reported on his achievements to a meeting of German physicians and naturalists in Bonn. Plücker supported him with the demonstrations of his experiments there. Meyer published another book in 1858. In the foreword dated September 1858, Meyer praised Geissler and his publication in Pogg. Ann., but failed to mention Plücker, which was certainly annoying. However, there was a dispute between Meyer and his chief Plücker who had more than enough other enemies in Berlin. Plücker had early recognized the potential of initiated by Geissler and opened by Meyer in Bonn research area, made their own investigations and from it a little later in 1858/59 developed the profitable field of spectral analysis of electrically excited gases. Already before in 1858 he had coined the term "Geißlersche tubes". Meyer opposed his physical views, includingPlücker's cautious reserve in

interpreting the phenomena observed angered Plücker, who oriented himself on the axiomatic mathematical approach, and thus fueled the conflict. When Meyer came to the public with his writing and the controversial remarks aimed at Plücker, that teacher-student competitive situation was already soured. Meyer had submitted his dissertation on problems of magnetism (completed during his work on glow discharge!) at the University of Marburg instead of Bonn. Meyer went to Marburg or to Berlin and there is nothing known about any of his later scientific successes. The conflict of priority appeared also at the Faculty of Philosophy in Bonn in 1868.[1325]

Figure 8-2: The first Guericke pump: one of the observing nobles could be Carniolan Auersperg.[1326]

Johann Wilhelm Hittorf was born in a trading family in Bonn, where he studied chemistry and physics and received his Ph.D. from Plücker in 1846. From 1852 to retirement due to ill health in 1889 he was a professor at Münster, where he also died.

In 1858, Plucker observed the influence of the lowering of pressure and the magnetic field on discharges in Geissler's tubes. After 1860, Plücker's research was continued by his student Johann Hittorf, professor of the Academy in Münster who proved to be much more obedient than Meyer.[1327]

The properties of "cathode rays" were studied in the 19th century with Ruhmkorff's induction apparatus[1328]. With a small DC voltage in the copper wire of the primary coil, it induced a giant alternating voltage on a secondary coil, which had a well-insulated thin conductor up to 500 km in length. With the current of two Bunsen batteries, the rabbit could be killed.

Clausius had initially an induction apparatus on polytechnics in Zurich which produced only 3 to 4 cm long spark. In 1857, he acquired a Ruhmhorff's inductors, with which he could obtain 27 cm long sparks. In 1862, Clausius acquired a large 800 mA electromagnet. Ruhmkorff's inductors, which cost 1000 francs, were also located elsewhere in German-speaking countries before 1861, for example, at the Polytechnic in Karlsruhe and at the University of Heidelberg.[1329] In the following year at the Ljubljana grammar school Mitteis purchased Ruhmkorff's inductor after he closely followed the development.

German **Heinrich Daniel Ruhmkorff** was born in Hannover, but he opened his store of scientific tools in Paris in 1839. He started to produce his famous inductors in 1848. In 1836, a similar device was already invented by priest Nicolas Callan (1799-1864) as an Irish university professor of natural sciences in 1836-1837 after Callan learned all about Galvanic and Voltaic discoveries during his theological studies in Rome.

Plücker acquired most of his experimental equipment in Paris. On the other hand, Plücker and Geissler supplied devices for the study of "cathode rays" to Gassiot and Töpler in Graz who were former Hittorf's students. In 1869, Hittorf launched a 16 cm long spark in the air with Ruhmkorff's apparatus. At that time, Geissler from Bonn sent "beautiful large tubes" to the new Habsburg physics institute in Graz. In them, Boltzmann observed the influence of the magnet on electrical charges in 1886 and 1887. From a small Ruhmkorff apparatus, they obtained 1 cm long sparks at a pressure of 1 mm Hg.[1330] Ruhmkorff's apparatus was also used by Boltzmann's teacher Stefan in Vienna.

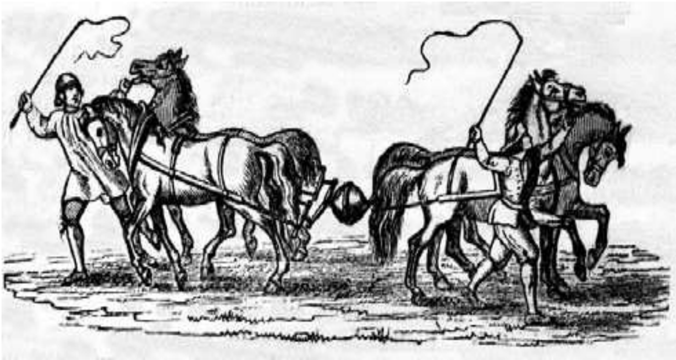

Figure 8-3: The experiment of Guericke and prince Auersperg of Carniola with Magdeburg hemispheres conceived by the professor at the Zagreb Higher Real School Slovenian Ivan Tušek (* 1835; † 1877) two centuries after the first experiments in his translation of Schoedler's Physics published in Braunschweig in 1865.[1331]

In 1867/68, Magdeburg hemispheres were re-acquired at the Gymnasium in Ljubljana. The following year, the curious Slovenes could read the description of Guericke's experiment in the native language: "... These hemispheres, which previously had fallen apart from themselves, fell tight one upon another, so that the six pairs of horses fused by rings from each other side, could not break apart the hemispheres" (Figure 8-3).[1332] Unfortunately, the reader did not learn much about Auersperg's merits in Guericke's experiment. The lack of proud memories always been a disaster in Carniola. Unfortunately, Carniolan contribution to the early vacuum technique slowly sank into oblivion.

Already Guericke (1672), Boyle and Hooke (1658) found that vacuum does not interfere with electrical forces. With the introduction of Geissler's electrical glow discharges in diluted gases, discharges in vacuum became fashionable electricity exploration. In a few years, they have been developed into a teaching aid. Geissler put metal pipes of platinum glass in the cathode ray tubes. His pump did not have a dead end in its operation and could reach a pressure down to 0.011 mbar. In 1862, Töpler at the University of Jena thus processed the Geissler pump so that it no longer needed shut-off pipes. This has reduced the available pressure fourteen times. In August 1868, Töpler was elected as a full-time professor of experimental physics in Graz. On 17 July 1876, he was a groomsman at a wedding of his collaborator Boltzmann and Boltzmann's former student, the half Slovenian Jetti in Graz.

Hermann Johann Philipp Sprengel from Schillerslage by Hanover studied in Göttingen since 1855 and received his Ph.D. in Heidelberg in 1858. The following year he became Assistant of Benjamin Brod at the University of Oxford. From 1863 he studied in London as a chemist at the Royal College of Chemistry and at hospitals Guys and St Bartholomew's. In the latter, chemistry lecturer William Olding enabled him to explore, which he crowned with his first pump in which he exhausted air from the tube with repeated successive mercury drops. The pump was immediately put into service, as Graham used it in 1866 to explore gas diffusion. At the University of Heidelberg in 1869, Bunsen compiled a "Wasserluftpumpe" from Sprengel's pump, developed by Gimingham and others in many versions. In 1865 Sprenger researched at the London chemical factory. From 1870 he lived as a private person, and eight years after he was selected in the RS. In 1881, he published a discussion on the vacuum pump in London and New York on 16 pages of large format. He died in London.

Berliner experimental physicists Jakobi, Steiner, Poggendorff and Magnus did not support the surveys of "cathode rays" of Bonn professor Plücker and his student Hittorf. The dispute emerged in the years 1832-1834, when Plücker was an associate professor in Berlin; Poggendorff later loved to irritate Plücker which might have propelled Meyer's mutiny. Geissler presented his pump at a gathering of German naturalists in Giessen, where his performance was watched by Poggendorff, editor of the leading German physical journal Ann. Phys. In September of the same year, Poggendorff presented his version of the mercury pump in London's *Phil. Mag*. Poggendorff described the idea of a pump on mercury as "very old, just as old as the pump itself. We have put Geissler as the inventor because he was the first to put together a practically usable pump."[1333] He praised Swedenborg's invention, thereby reducing the significance of Geissler's and

[1331] Tušek, 1869, 94 figure 111; Schoedler, 1865, 82, figure 111.

[1332] Tušek, 1869, 93–94.

[1333] Poggendorff, 1865, 153, 158; Wüllner, 1870, 365–366.

Plücker's surveys.[1334] Of course, Plücker also had followers; among them was Wüllner as his private assistant since 1865, whose textbook has been used by Slovenian Stefan as a source of information for his famous radiation law.

Due to a dispute between physicists from the Prussian universities in Berlin and Bonn, Plücker's work was recognized and translated in England more than in Germany. Thus, there was no proper connection between Plücker's and Hittorf's cathode-ray light surveys and concurrent studies of the Kirchhoff-Bunsen spectral analysis at the University of Heidelberg. Initially, they explored only the spectra of vapors of ordinary metals and did not notice that the spectrum of the same gas could change under different conditions of annealing. They used a burner that was compiled by Bunsen a year ago. Kirchhoff reported on his research for the first time to Berlin's academics in October 1859, of course, without mentioning Plücker. Explorations of glowing vapors in the spectroscope and in cathode ray tube tubes were only linked in the 1870s when Crookes successively achieved valuable results in both areas. The German Hermann Sprengel described a pump in which mercury droplets covered and removed parts of gas in glass pipes in London in 1865.[1335]~~5.~~ The new process was slower than Geissler’s, but it allowed multiple pumping and therefore a better final vacuum down to 0.1 Pa.[1336]

8.1.2.2 British Vacuum Researchers and Crookes

In 1873 Crookes assembled a radiometer to study the amount of radiation. He linked his findings to the research of vacuum tubes and in 1876 he designed the theory of the fourth aggregate state of matter. During this time, he participated in spiritual research,[1337] which surely influenced the boldness of his hypothesis.

His pioneering method was initially accepted as evidence of the "cathode ray" pressure. Between 1873 and 1876 he was very popular in scientific journals and challenged the controversy between Maxwell and Osborne Reynolds. Unfortunately, the difference in the pressure that propels the radiometer comes from temperature differences and does not measure pressure of waves of light at all. Crookes had other ambitions too: only in the mid-1880s Crookes finally abandoned the program designed to achieve his absolute vacuum.

8.2 Slovenian Vacuum Researchers after the Invention of the Cathode Ray Tube

8.2.1 The Equipment of Slovenian High Schools during the Great Progress of Vacuum Technology

In the second half of the 19th century in Slovenia there was no teaching facility that would exceed the upper secondary level. Therefore, some of Slovenian schools, especially the Ljubljana gymnasium, were among the best in the monarchy of that level. They maintained with well-equipped cabinet of physics in which they did not miss any devices for demonstrating the vacuum. Kersnik's and Mitteis’ inventory lists of the cabinet of physics in Ljubljana indicate on average about forty devices connected with vacuum and overpressure in the middle of the 19th century. The devices were massive and mostly made of bronze, so that they survived a century of demonstration experiments and today still arouse admiration at the Slovenian School Museum in Ljubljana, where they are waiting for a suitable exhibition space. The experimental tools devices connected with vacuum and overpressure were noted according to the censuses of higher studies and later Grammar school in Ljubljana during a century between Erberg (1755) and Mitteis (1866). Among them, by far the most expensive were the double-sided air pump valuated at 147 florins or 157 florins 50 kreuzers which was acquired in 1858 and the older model of the steam engine (Table 8-1).

The schools outside Ljubljana also liked to buy gauges. Thus, a metal barometer was purchased as the "Bourdon tube" at the Gymnasium in Koper in 1875, ten years after the Gymnasium in Ljubljana. It measured the deflection of the elastic element due to external pressure (Figure 8-4). Eugène

aneroid barometer	1872	Celovec
Fortin's barometer, »Bourdon's barometer«, manometer	1875	Koper
aneroid barometer with thermometer	1893	Koper
Barometer	1895	Koper
model of aneroid, gasometer	1901	Koper

Bourdon (1808 Paris–1884 Paris) patented his aneroid metallic tube pressure gauge in 1849.

Let us look at the pressure gauges in inventory and censuses in Koper and Klagenfurt in the second half of the 19th century.

During the period of rapid development of vacuum research after to the invention of the cathode-ray tube the schools in Slovenian lands supplemented their cabinet of physics with more modern manometers in the second half of the 19th century. On September 22, 1870, at the first independent exhibition of teaching aids in Ljubljana, the professors of "imperial royal c.kr. teacher preparatory" displayed their "physics apparatus in images". Among other things, they also displayed images of "gasometer and gas container".[1338]

In the Slovene ethnic territory, they were interested in cathode ray tubes discharges at an early age. The cabinet of physics were not intended for students only. The Bohemian German Mitteis, professor of physics in Ljubljana from 1853 to 1866, director of gymnasium and for some time also the director of Ljubljana real school, demonstrated his most interesting purchases in front of the selected company of educated locals in the Carniolan Museum in Ljubljana. The physicist Thomas Schrey, Mitteis's substitute (suplent) teacher, supplemented Mitteis' lecture on the development of a stereoscope with the introduction of the latest methods for measuring the magnitude of the electrical spark. Schrey was born in German speaking family in Logatec in 1830. Between 1862 and 1870 he was the director of the Ljubljana Real School where he taught physics as Peternel's and Hugo Ritter von Perger's superior. Schrey also taught physics and chemistry in Ljubljana Sundays trade school connected with his Real School. The Slovenian Carniolan national politics was not his favorite, so, Schrey went to lecture in mathematics and physics at the Real School of Klagenfurt where he lived in Groβe Theatergasse no. 54 of south part of downtown Klagenfurt in 1876. Like his friend Dežman for Carniola, Schrey used the barometers to update a quarter of century earlier Prettner's estimated heights of the hills in Carinthia up to June 1876. Like Dežman and Mitteis, Schrey measured earthquakes in 1897. Schrey died in Annabichl (Anapigelj) in southern part of Klagenfurt in 1909.

After Schrey left for Real School directorship, in the school year 1862/63 Mitteis acquired five Geissler's cathode ray tube for the students of Physic in Gymnasium in Ljubljana (Figure 8-4). He acquired Ruhmkorff's induction apparatus for 120 fl, which exceeded half of the annual grants of the cabinet of physics.[1339] He bought another

[1338] Günter Reich, Wolfgang Gaede, v Redhead (ed.), Vacuum Science and Technology, Pioneers of the 20th Century, History of vacuum science and technology, Vol. 2, AIP Press, 1994, 53; Lafferty, 1998, 381.

[1339] Mitteis, 1866, 61.

strong magnet with three lamellas and raised it to 7 kg.

In 1867/68 Mitteis's successor Jakob Rumpf, curator of the Cabinet of physics of the Gymnasium in Ljubljana, acquired "electromagnetic apparatus for rotating Geissler's tubes".[1340] It was Geissler's refinement of de Rive's electromagnet, adapted for twisting and rotating of the light arc in Geissler's cathode ray tube.[1341]

Figure 8-4: Geissler's glow discharge tubes filled with dilute gas in Mitteis' inventory list at the Gymnasium in Ljubljana at the end of the second semester, on August 1866. Geissler's tubes and their stands were listed as 62nd and 64th device for experiments in electricity.[1342]

At the Grammar School in Koper, the docent of mathematics and physics Stefano Hamerle from Rijeka Civil Technical School (Civica Scuola Tecnica) was employed on 7. 10. 1867. He purchased the first Geissler's electrical glow discharges in diluted gases together with Ruhmkorff's inductor in 1870[1343] and the second one in 1897. The graduate of Viennese Polytechnic engineering Orlando Inwinkl (Inwinkel, * 1880 Barban (Barbana) in southern Istria; † 1936 Colombes in the northwest suburb of Paris) became the supplied professor of mathematics and physics in Koper on 12. 10. 1904. In that time the Grammar school library in Koper had many books about physics published in 18th century and later:

In 1906/1907, Orlando Inwinkl as curator boldly complemented the Koper collection with Luigi Palmieri's (1807–1896 Naples) induction apparatus, the didactic set of Geissler's cathode ray tubes, six different Geissler's tubes for electrical glow discharges in diluted gases, a collection of six Crookes cathode ray tubes, radiometers and the special Crookes cathode ray tube to show the shadow of "cathode rays" behind a Maltese cross. Inwinkl bought Hittorf's cathode rays tube and two X-rays tubes.[1344] Later, Inwinkl taught in Trieste, became a socialist antifascist leader in Monfalcone Partito Socialista Italiana (PSI) in April 1913, director of the fabric of agricultural machines in Windsheim of Bavaria. Chased by the Nazis, he left for France and Switzerland in 1931.

Most of Inwinkl's Koper experimental tools were designed to study "cathode rays" in the Geissler tube. His Ruhmkorff device was used for a voltage source of several kV, and the magnet was used to deflect the rays. Three to four cells in the Grove Zn-Cu battery provided a sufficient current that could induce higher voltages in the Ruhmkorff coil

Ivan Šubic from Poljane above Škofja Loka attended the Grammar School in Ljubljana between 1867 and 1875. He studied natural history and mathematics in Vienna, and he listened to Stefan's Viennese lectures for the first time in 1878. He completed the qualification exam in 1881, and in the same year he was employed at the Mahr's Trade School in Ljubljana as a substitute (suplent) teacher. I. Šubic later taught in the Real school and gymnasium in Ljubljana. In 1888, he received a lengthy leave to study at the Technology Crafts Museum in Vienna, where he also visited several other schools and art academies. In August 1888 he became a teacher and head of a newly established professional school for woodworking, and a professional school for artificial embroidery with sewing in Ljubljana. After the merger of both schools, he became director of the State Craft School in 1911. This later got its new higher departments of construction and mechanics, and in 1920/21 it was rearranged into a technical high school. Between 1890 and 1907, I. Šubic was a consultant to the municipality of Ljubljana and led the construction of a plumbing and the electricity power plant as the head of the management board of the municipality. Between 1898 and 1901 he was a Member of Parliament for Kranj and Škofja Loka. As a longtime member of the Slovene Matica (SM), together with Fran Levec, he became head of the SM department of books between 1904 and 1911. From 1904 he was the supervisor of the Slovenian continuing arts schools in Carniola, Styria and Primorska (Littoral), and in 1922 he became a senior supervisor for trade and craft education. For seventeen years, he was a conservator with the Central Commission for the Protection of Artistic and Historical Monuments. In addition to the book on electricity, he published numerous natural science works in the Ljubljana School report, Ljubljana Zvon journal and in the Letopis (Yearly) of SM.

[1344] Inventory Koper, no.265, 268; Journal of Grammar school (Izvestja Gimnazije) Koper, 1897; 1905: 37-39, 44, 1907, 61; 1908, 56.

than in the strongest Leyden jar.[1345] The new Ruhmkorf's inductor finally proved to be better than the apparatus of the previous century, just like the vacuum pumps finally offered better experimental facilities compared to barometers, steamboats bettered sailing-boats capabilities or planes replaced balloons.

Ruhmkorf's inductor was necessary for experiments with Geissler's cathode ray tubes. A set of more than ten Geissler tubes of various shapes and a Ruhmkorff induction apparatus were later acquired by the Lower Real school in Kočevje in 1872, which developed into a higher Real school between 1908 and 1911.

Soon after Geissler's invention, the cathode ray tubes became the subject of secondary school physics. Then high school professor could be more successful than today in the fundamental experimental physics.

8.2.2 Šubic's Research on the Transmission of Electricity in Gases at the University of Graz

Ivan Šubic's older relative from Poljanska Dolina S. Šubic was an associate professor at the University of Graz between 1869 and 1902. From Reitlinger and Clausius' (1858) works S. Šubic supposed that the average free path of the molecule is inversely proportional to the density of the medium. However, Š. Šubic wrongly concluded that rare gases better translate electrical and thermal disorders compared to the denser ones. The claim was contrary to Maxwell's kinetic theory from 1859 and 1860, according to which the thermal conductivity does not depend on the pressure and density of the gas, down to the low pressures where no significant interaction between the surface and the gas remains. In 1860 in Berlin Magnus and a decade after him Stefan in Vienna confirmed Maxwell's assumption.[1346]

S. Šubic has purchased several Geissler tubes among eighteen electromagnetic instruments for his collection of cabinet of physics in Pest in 1858/60, only four years after the invention and three years before Mitteis in Ljubljana. In his high school textbook Šubic only mentioned the "superb" electric current in the emptied tube, without describing an experiment with Geissler's cathode ray tube. Considering the experimental orientation of his textbook, we assume that between 1872 and 1874 Šubic hesitated with his opinion about effects in Geissler tube. Šubic's and Hittorf's theory of electrolysis was based on the movement and collision of molecules. S. Šubic extended his similar findings to gases. He was the most interested in the events in the vacuum tube with the electric voltage applied at the extremities. Šubic's velocity of the collisions between the molecules, the voltage, the conductivity, and the spark length were inversely proportional to the gas density in the vacuum tube; therefore, a rarer gas obtained the higher the rate of propagation of molecular collisions, better conductivity and greater luminosity.[1347]

The above findings at least partly contradicted the modern kinetic theory that developed in the late 1850-s. The thermal conductivity of gases does not depend at all on its pressure and its density over a wide area, until at low pressures there is no longer significant interaction between surface and gas. In 1862 Šubic was still not aware of Maxwell's theory of the conductivity of gases from 1859-1860, which Clausius corrected in 1862, although Šubic should have known Magnus measurements which supported Maxwell's ideas.[1348]

Of all the phenomena in the Geissler tube, Šubic was most interested in "stacking of electric light". He must have assumed that it was a spark of continuous discharge in gas. In 1876, Hittorf considered that cracking was caused by voltage, too weak to produce constant light. Gassiot in 1863, Stokes in 1864, de la Rive in 1867, and Wiedemman in 1872 and 1867 opposed Hittorf's opinion.[1349]

According to Šubic, the gas in Geissler tube radiates the light due to heating during transmission of electricity caused by electrical resistance or internal friction. Šubic summed up Reitlinger's opinion, confirmed by spectral analysis. The conductor should be brighter as its electrical resistance turns greater. Šubic and most others thought that there were no chemical

1345 Ganot, 1886, paragraph 849, 800, 803.

1349 Šubic, 1862, 106; Hittorf, 1889, 181.

reactions in Geissler tubes, or they were at least extremely slow. According to Šubic, the mean free path of particles during transmission is inversely proportional to the density of gas, and the mass of the particles is inversely proportional to the square of their velocity.

Both equations were derived from kinetic theory. In gases the resistance is much lower than in the liquids, where according to Šubic the second claim does not apply. The speed of the particles in denser liquids is greater than the speed in the rarer ones, if the radius of the particles in denser liquids is larger or equal to the radius of the rarer ones.

Šubic explained the dark area along the cathode of the Geissler tube by the spread of the collisions between the molecules which in Šubic's theory was an electric current itself. Immediately at the source of the motion in the cathode, there cannot yet be enough collisions with the gas molecules in the vacuum tube to produce any observable light. The sparkling is observed in more distant parts of the Geissler tube.

Šubic's ideas were much like the Crookes' opinions of 1869. However, he did not write straight that the length of the dark region along the cathode would be proportional to the average free path of the molecules in the gas. The dark area of the cathode is now called by Crookes' name. In the case of normal discharge, where the density of the electric current does not depend on its intensity, Crookes theory is valid. The length of the "dark area" is inversely proportional to the pressure or density of the gas in the tube. At extremely low pressures, the "dark area" can be stretched over the entire tube.

According to Šubic, the gas is concentrated in narrow areas of the Geissler's electrical glow discharges in diluted gases because its volume decreases with the same mass of the gas substance involved. The flow of matter through the tube is therefore continuous because it has no sinks or springs in a pipe with only two electrodes. According to Šubic's opinion, the gaseous contents of the tube are indeed entirely thickened everywhere, and not only in its radiating part.

Similarly, Šubic declared luminosity as proportional to the resistance of the gas in the tube.[1350] Like the electrolytes, gases should translate electricity with the movement of ions. This is contrary to modern theory, since the ions do not move in the cathode ray tube, while the electrons do.

The modern theory of translation in a vacuum tube is much closer to Hittorf's theory,[1351] which offered another different mode of translation in gases ~~when~~ besides the motion of ions. Those motions cause glare in the gas, today we would say transitions between excited states of gas atoms.

Another way of Hittorf's translations had all the characteristics of radiation. Even though Hittorf did not specify that analogy, the events in the Geissler tube are completely like the thermal phenomena that combine translation and radiation. During the time of prevailing Puluj's (1888) theory of the translation of electricity in the diluted gases, Hertz detected electromagnetic waves and finally confirmed Maxwell's theory of the electromagnetic field.

Ten years later, J. J. Thomson showed that radiation and translation in gases cannot be explained simply by the wave itself. The "cathode rays" in the vacuum tube consist of particles to which J. J. Thomson has measured a charge-to-mass ratio. Crookes's presumption of the particle nature of "cathode rays" was victorious against his German opponents, at least for two dozen years until the noble duke de Broglie's wave-particle duality of 1924.[1352]

Šubic's publication from 1862 was created for a whole decade before *the* exploration of Geissler's pipes began to promise the resolution of the problem of electricity and the elimination of the electrical substance without weight.[1353] Šubic did not say in his work that radiation from the cathode is negatively charged and can be rejected by a magnet.

8.2.3 Šantel's Vacuum Pump at the Grammar School in Gorizia

In 1869, the Slovenian Tušek, a professor at the Zagreb Higher School in Zagreb, published a

sketch of a pump with a double cylinder alike Hauksbee's model, which was still the most effective just before the Geissler invention: "We see a glass bell which is named as the connector (recipient); the edge is lubricated with a tallow, and is connected to the plate R, to the so-called pump’s panel, so that it does not pass the air through. The panel has the hole in the middle, so that the bell is connected by means of a pipe in relation to both the cylinders D and S, whose pistons are spinning up and downwardly with the help of two toothed bars, wheels and double barrels, thereby diluting the air in the bell. For this, they also need cocks, specially perforated, and flaps (Valve). The valves are devices that start to open themselves, if the air is pressing from one side to the other; and which closes by itself, if the air is pushing from the opposite side. Therefore, it is called the air suction device according to how it is made, either the suction pipe or the pump with the valve (Figure 8-5)."[1354]

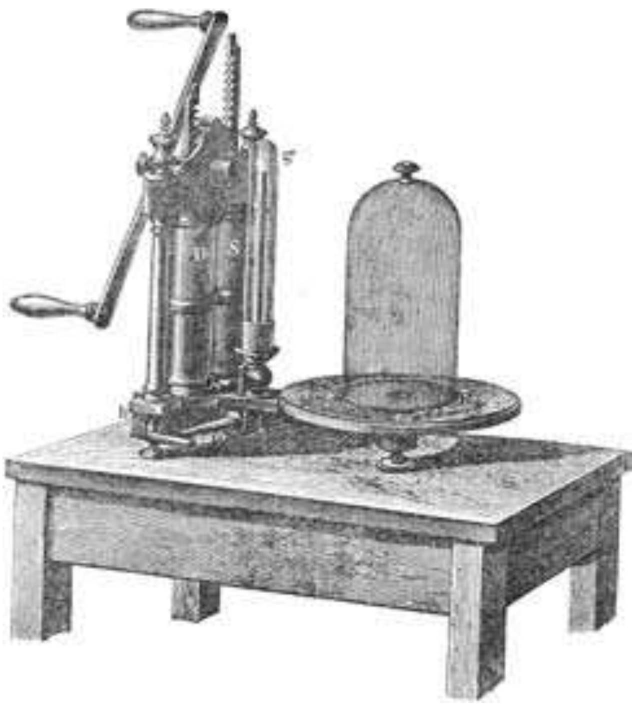

Figure 8-5: Vacuum device which Tušek introduced to the Slovenes[1355]

More than two centuries after the invention, the vacuum pump still seemed to be very important to Tušek and Schoedler. For this reason, he kept it on the cover of his translation of Schoedler's physics in addition to the telescope, the Voltaic battery, the friction device, the electroscope and other tools (Figure 8-6). Slovenes are an ingenious people in the disposal of foreign winds. Therefore, the Slovenes quickly found out that they can improve German vacuum pumps. The greatest achievement after prince Auersperg belongs to Šantel, the Slovenian Styrian in the Coastal Service, who published five discussions in his reports of the Gorizia State High School. He was born in the Slovene family of cottagers in Pesnica by Lučane on Kozjak. From 1865 he studied mathematics and physics in Graz with former Ljubljana professor Hummel and Töpler. In 1872, he became a professor of physics at the Gymnasium in Gorizia. During the First World War, he had to flee to Krško. Šantel's wife, their daughter Avgusta and son Saša were famous Slovenian artists. In 1873 and 1876, Šantel and Boltzmann married two sisters, the half Slovenian Avgusta Aigentler and two years younger Jetti. The family of Šantel spent many holidays together with the family Boltzmann. Šantel's son, Saša, used the help of the Viennese family Boltzmann during his studies in Vienna.

Physicists Šantel and Boltzmann collaborated, as Boltzmann quoted Šantel's mathematical treatment of gas diffusion in 1883.[1357] In the same year, Šantel assembled a vacuum pump, which Boltzmann considered in his experiments with Geissler tubes in Graz in 1886 and 1887.

In 1883, Šantel was mainly interested in vacuum pumps. In 1883, Šantel designed a vacuum pump, which his brother-in-law Boltzmann in Graz used in his research. As a curator of the cabinet of physics Šantel bought Töpler's model of mercury vacuum pump and Edison's bulb in 1882/1883. At the same year, the grammar school of Gorizia student of seventh class Gorizia native Lovisoni Vulmar (abt. 1866 Gorizia) assembled and donated to Šantel's lab the apparatus of the deputy of secondary schools (Oberschulrath) of the German state of Baden the physician Joseph Frick (Frik, 1806-1875) for the convenient cutting of glass tubes, which Šantel certainly used in the construction of his own pump. Lovisoni Vulmar later got his Ph.D. and became a member of the city deputy (*membro della Deputazione comunale*).

Šantel mentioned Torricelli, Töpler and Geissler as inspirators of his vacuum pump. In 1854, Geissler achieved a pressure of 0.01 mm Hg in Bonn with his pump. Töpler was set up in Bonn as a chemist at the Landwirtschaftsakademie Poppelsdorf since 1859. In 1862, he invented a simple barometric air pump for high vacuum without pipes, valves and excess space, which was domesticated at all physical institutes, including Šantel's grammar school lab in Gorizia. Töpler pump could reduce the pressure of the Geissler pump by fourteen times. Between 1868 and 1876, Töpler was a physicist in Graz, while his Physics Institute was the largest in the German language areas at the opening in 1875 which affected the neighboring Slovene lands. Šantel was Boltzmann's every and occasional associate, and Töpler was Boltzmann's groomsman. Thus, Šantel and his teacher Töpler knew each other well too.

Šantel made an air pump for observing discharges in a vacuum. The basic problem of the previous pumps was poor sealing of the valves and the fragility of the thin glass wall of the vacuum tube, which often collapsed under large pressures. Šantel's vacuum pump discharges avoided bad airtight near the cocks and the flimsiness of the thin glass wall of the vacuum recipient, which often broke due to extended pressure. Šantel's attention was drawn to the physics of high vacuum produced by the draining of mercury along the tube. In it, the electrodes could be strongly charged. Šantel focused his attention to the announcement in a professional physics journal about a high-vacuum achieved by the mercury flow through the tube. In such a vacuum, the electric spark did not discharge prematurely over short distances; so, it was possible to achieve high voltage between the electrodes. In Šantel's pump, the freely descending mercury pumped air from the container. A sufficiently long mercury column broke in the pipe under its own weight with a great noise and left an empty space behind itself. In wide tubes, the high velocity of decreasing liquids in the vertical direction prevented the formation of the bubbles of air.

Šantel warned against the use of rarefied liquids more volatile than mercury, since larger pumps should be used for the pumping out the air with them. In the first experiment, he placed the bottle by the wall which was close to 2 m high. He sealed it with a rubber stopper on the valve and put the glass tubes through it. For his first experiments he chose a 2 mm diameter capillary nearly one foot long and open on both sides. The second tube was shorter and thinner, with the rear pointed side placed in the opening of the first tube.

Šantel connected the freed bottom end of the pump tube to a pot filled with a mercury. Under the lower end of the tube in which mercury dropped, he placed a trap for intercepting. The upper collector was filled with mercury, which quickly flowed downwards. In the pumping tube, mercury was placed up to the height of barometer.

In the second experiment, the recipient was placed in the neck of the bottle with a rubber stopper under 120 cm long horizontal tube. A small opening in the wall near the lower end of the tube was softened with flame. Šantel touched the softened part with a glass rod, sharpened it and removed the top to make a small opening.

The other end of the pipe was immersed in mercury. He placed an empty jar under the recipients of the air pump. When Šantel poured mercury into it, he started pumping. He described the operation of the pump as very good, because

[1357] Boltzmann, 1909, 3: 62, 697.

"man cannot believe his eyes when he watches movement in the tube".

The cylinder made of glass had a diameter of 3 cm and a height of 15 cm. Šantel placed rubber stoppers on the same axis with the two apertures of the cylinder. The space between the stoppers was used for a mercury collector. The upright cylinder was put at a height of 2 m, mounted on a wall or onto a portable wooden stand.

In one of both holes of the bottom stopper, a pipe was laid with strong walls of an inner diameter of 2.5 mm which had 140 cm of length. Through the upper hole above the hose, a pumping hose-tube b was placed with the end in the hole a. Through the second hole of the lower stopper, the mercury supply to the interior spaces was adjusted through the tube c. The pipes c and a had the same shape. Near the end, Šantel had a C-gauge tube with an opening of the width of the hair, which was ending in the interior space A near the upper stopper.

The pump b reached outside the cylinder into the barometer and remained paralleled for further 20 cm. Pipes a and e close to each other emerged from the cylinder A. At the same height, they were soaked in a mercury container B. The pneumatic tube d was closely connected by the rubber tube to the secondary air pump. Šantel was particularly interested in resolving the following puzzles:

1) Will mercury flow up from container B to a higher put vessel A?
2) In this case, will the flows in the pipe c and in the pipe a balance each other?
3) Is the extraction of the air from the recipients fast enough for the practical use of the device?

The first question was affirmatively answered by the start of operation of the pump. The second question emerged from the change in the mercury flow in previous failed experiments. While focusing on the third question, Šantel found that the barometer showed a "zero density" after 1 minute of pumping; with the naked eye it was no longer possible to detect any differences in mercury levels in the arms of barometer.

Šantel solved most of his pumping problems:

1) Space A was only slowly filled through the capillaries of pipe of thickness c, so he used thicker pipes.
2) The mercury column core in the pipeline went up into area A and further up into the aperture of the pneumatic tube. The sealed end of a pipe rejected well the striking mercury drops.
3) Due to the dilution of air in room A, the stopper was pressed even further closer to the cylinder, so that the pumping tube was tightly put in the first tube. The stopper separated the space A into two unequal parts and pushed its pressure against each on them. Šantel eliminated problems 2 and 3 by using a vertical shaped glass envelope in the cylinder axis A that impeded the flow of air.
4) The amount of mercury was regulated in the inner vessel when it filled space A to the desired height. The bottom end of the tube was no longer immersed in the mercury collector. The air was no longer running along the tube level and did not change the level of mercury. Šantel recommended using the recipients in the pump. To extract the large spaces of the Geissler's tube, the recipients had to be connected directly to it as the described small dimensions were not useful for pumping out large spaces of Geissler's tubes. He placed 12 inches high, slightly pointed-shaped glass bowl of strong walls in the cathode ray tube. It was sealed by a three times pierced rubber stopper of about 3 cm. In one hole there was a pumping tube from which the curved barometer continued. Šantel placed another barometer in the second tube, and in the third tube he had his recipients. When Šantel introduced and connected all three tubes, the mercury flooded the space in the container above the stopper. This ensured a constant density of air.

The filled recipient's tube had a U-shape with a longer capillary of 76 cm long. The end of the capillary touched the mercury level, which filled half of the container. The tube reached the surface itself without being sunk. In the end, it was linked to recipients. The smoothness and level of the mercury was controlled by a steel wire in a stopper which was carrying a steel cylinder. The steel cylinder usually floated above the surface of mercury, but Šantel could have it sunk together with steel wire to regulate the level of Hg in the U-tube. The pump was described in five points.[1358]

Šantel pumped the air from one receiver. The pump was initially manually loaded and adjusted

[1358] Šantel, 1883, 28, 35.

to the size of the long flexible piston. In his late thirties, the professor Šantel did not find the work particularly tiring, as he could rest in the meantime. A mercury piston pumped air from the vessel. The pump could be easily assembled, and the glass tube was easily bent in the fire. Šantel mutually connected all parts with rubber stoppers and Šantel easily replaced them if some unhappy falling or fracture happened. The price was not high, and the apparatus can be completely disassembled and cleaned. Unfortunately, some mercury was lost during pumping; therefore, environmentally friendly Šantel used a small amount of mercury to limit pollution although he could not be aware of the toxicity of mercury in those early times.

Šantel said that after the prolonged use of his pump the mercury was covered with black sulfur from rubber stoppers that lubricated the glass wall. Mercury friction along the glass wall of the vessel caused electricity and the formation of ozone that was oxidizing mercury much more than the ordinary oxygen.

The capacity of the pump was further increased by an outer tube of a larger internal diameter. Šantel particularly liked to see the mercury flowing through a paper funnel in an upright tube in a darkened room and admired the phosphorescent sparkled brightness.

In the further discussion of 1883, Šantel considered the electric repulsion of liquids described by his "collaborator's discussion", which he did not specify in more detail; maybe that collaborator was Boltzmann himself and Šantel was polite enough not to glorify his own work with his brother-in-law's fame. Similarly, Šantel inadequately quoted the source of his idea of a device for converting the solar heat into mechanical energy. The idea was supposed to be "published in several professional journals in 1874" which could mead Exner and Roentgen's Viennese publication.[1359] Šantel used three glass vacuum tubes, placed at the angles of 60 degrees between them. The motor with rotating blades was propelled by evaporations from the bottom of the heated hot ether, which was driven through the glass tubes. This "engine" could have been running the clock for several months. There was no air in the glass tube with the engine except the vapours of the ether. At the conclusion, Šantel also assessed the efficiency of his device which otherwise resembled the older Crookes' radiometer but, Šantel differently used the steam of vapors of ether.

Šantel was interested in converting solar energy into mechanical work and, above all, in a new way of transmitting sound, known as Bell's phone since 1876. Before Bell the phones were designed by a natural science teacher in southern Germany, Reis, who never succeeded in calling anyone.[1360] Šantel also described the phone's peculiarities by the equations of the membrane magnetization in it. Imagination led him to a parallel telephone transmission of picture and sound[1361] in television which inspired Šantel's student Nardin few years later.

Šantel devoted to each study a special chapter. The first section on the vacuum pump on almost ten pages was nearly so long as the other three studies together. As a gifted experimenter and mathematician, he collaborated with his brother-in-law Boltzmann, a professor of general and experimental physics at the University of Graz. Undoubtedly, Šantel's work so far understudied was an important Slovenian contribution to the progress of vacuum technology, which at that time became a driver of technological progress.

8.3 Breakthrough of Vacuum Technology into Industry at the End of the 19th and Early 20th Centuries

The field of technical uses of vacuum in industry began with light bulbs at the end of the 19th century, and over several decades prevailed in all pores of the modern technology. Edison quickly embraced Crookes' vacuum technique and used it in the industry. In 1879, he started to produce carbon-filament lamps at the pressures of the thousandth of a torr. In Europe, similar production was only introduced at the end of the century. Vacuum technology has thus become the basis of

[1359] Wilhelm Conrad Röntgen & Franz Serafin Exner, Über eine Anwendung des Eiscalorimeters zur Bestimmung der Intensität der Sonnenstrahlung. *Wien. Ber*. II Volume 69. February 1874.

[1360] Beyer, 1999, 110.

[1361] Šantel, 1883, 42, 44–47.

large-scale industrial production, and many researchers have used vacuum technology in basic research. Pumps with solid pistons have greatly improved to serve better the bulb industry. In 1892 the Londoner diving engineer Henry Albert Fleuss (1851 Marlborough in Wiltshire-1932) invented and in the following year got a German patent for a piston pump sealed with oil. It had mechanical displacement dampers. In Guericke's honor, he named his invention "Geryke's pump" and reached $2.6 \cdot 10^{-4}$ mbar. Despite the worse vacuum, the pump had an advantage over older pumps with a liquid piston, as it was able to propel the engine. It delivers an almost constant suction because it uses a cylinder divided in halves: as one half of the cylinder is filled with air, the other half is evacuating air to the atmosphere by a stroke of the pump. The next stroke reverses that action to produce the constant flow. It was used in the light bulb industry until 7. 9. 1955. As an assistant at the University of Freiburg, Gaede patented circular-acting motorized pumps and a mercury piston. With it, the experts reached 10^{-6} mbar; so, the device became extremely useful in the lighting and cathode-ray industry. Gaede replaced the glass casing of older pumps with metallic casings, and he used the rotary drum made from porcelain.

One year before Leybold's death in 1906, his firm began working with Wolfgang Gaede, who developed vacuum pumps for Leybold;[1362] mostly a molecular pump in 1911/12. Gaede demonstrated yet another novelty to the 77th meeting of German naturalists and physicians in Merano in Lower (South) Tyrol. He received a great attention and

numerous offers. All listened and were interested in buying options. Gaede's report from the meeting was later read by his eleven-year-older chemist Alfred Schmid, son of the owner of machine-shop of E. Leybold's heirs. Schmid was well over a decade older than Gaede, and he immediately smelled a profitable bargain. In that time that the company was in trouble because the competitors were licensed to produce "Guericke's (Geryke's) Pumps". That is why Schmidt went to Freiburg with his first morning train in February 1906. He signed a contract with Gaede on 23 April 1906 and began one of the most fruitful collaborations between a scientist and industry which lasted for

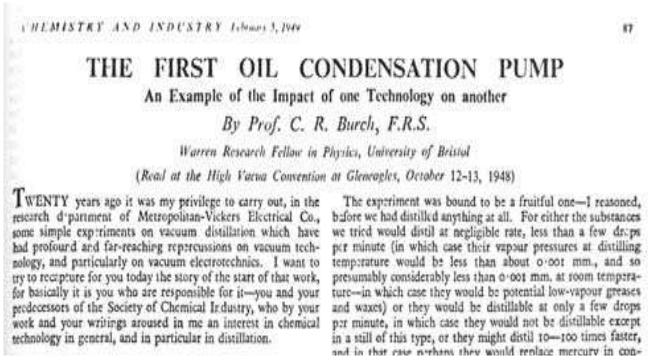
Max Paul Wolfgang Gaede was the son of the Prussian artillery officer and therefore often moved through different German cities. In Freiburg, he first studied medicine and then graduated in physics from Franz Himstedt's class in 1901. Himstedt excelled with his experiments in electrodynamics. On February 26, 1904, as Himstedt's assistant, Gaede described his own experiments in a vacuum for the first time. After the war, in 1919, he received a regular full professorship in nearby Karlsruhe. His inventions were indispensable in physics laboratories. That is why Lenard proposed Gaede for the Nobel Prize in 1926, but the Swedes were not convinced. Although the Nobel Prize-winning Lenard was a high-ranking Nazi man, the Nazi authorities nevertheless deprived Gaede of his professorship in a very humiliating way on 30 June 1934, two months after Göring ceded the leadership of Gestapo to Himmler and his associate Reinhard Heydrich. Gaede was a victim of barbarous era witch hunt after two of his jealous employees denounced to the Gestapo that Gaede called the National Socialists "childish". Gaede had to retire, although all he proved accusations to be false. To enable Gaede to continue his work, Leybold set up an interim laboratory and store at Gaede's home. In 1940, despite their kind attention, however, Gaede, together with his laboratory, moved to Munich, where he died shortly after the end of the war.

Wolfgang Gaede (* 1878; † 1945)

[1362] Leybold, 1994, 8.

thirty-eight years. The following year, Leybold equipped Gaede with a hardware store, which in 1912 became part of the university. In the same year, Gaede invented a "molecular" pump. Gaede proved to be an extraordinary acquisition despite of false denunciations of two Gaede's employees in 1933/34.

Leybold sold its first sixty samples of the new type of pumps in the same year 1912, and they sold a total of 300 by 1923, when the severe economic crisis broke out worldwide. The "Molecular" pumps were developed to reach 10^{-7} mbar in the next three decades.



CHEMISTRY AND INDUSTRY February 5, 1949 87

THE FIRST OIL CONDENSATION PUMP

An Example of the Impact of one Technology on another

By Prof. C. R. Burch, F.R.S.

Warren Research Fellow in Physics, University of Bristol

(Read at the High Vacua Convention at Gleneagles, October 12-13, 1948)

TWENTY years ago it was my privilege to carry out, in the research department of Metropolitan-Vickers Electrical Co., some simple experiments on vacuum distillation which have had profound and far-reaching repercussions on vacuum technology, and particularly on vacuum electrotechnics. I want to try to recapture for you today the story of the start of that work, for basically it is you who are responsible for it—you and your predecessors of the Society of Chemical Industry, who by your work and your writings aroused in me an interest in chemical technology in general, and in particular in distillation.

The experiment was bound to be a fruitful one—I reasoned, before we had distilled anything at all. For either the substances we tried would distil at negligible rate, less than a few drops per minute (in which case their vapour pressures at distilling temperature would be less than about 0·001 mm., and so presumably considerably less than 0·001 mm. at room temperature—in which case they would be potential low-vapour greases and waxes) or they would be distillable at only a few drops per minute, in which case they would not be distillable except in a still of this type, or they might distil 10—100 times faster, and in that case perhaps they would replace mercury in con-

Figure 8-7: Front Cover C. R. Burch's Discussions issued two decades after his Oil, Greases, and High Vacua, published in Nature in 1928.1363 He left Metropolitan-Vickers for academic research in G.P. Thomson's Imperial College in London after the tragic death of his elder brother Francis Parry Burch (1899-1933), another brilliant son of the optician George James Burch FRS (1852-1914).

In 1913 Gaede investigated the opposite flow of mercury vapor and air in a vacuum system pumped with a rotary pump. Similar research has been done by others; so, Russian professor Stanislav Antonowitsch Borovik (Borowik Станислав Антонович Боровик, 1882-1958) in Leningrad and Gaede in 1915 and Langmuir later independently invented a diffusion pump with mercury vapor. This were the first vacuum pump without moving parts, which Langmuir patented in 1919 and 1921, and Gaede in 1923. Both used a separate stand-alone position in their leading industrial company as a basis for their exceptional discoveries (Figure 8-7). Borovik worked in the first Russian Roentgen-tubes lab of N.A. Fedoritzki. From there Borovik reported his invention on Section of Physics of Russian Physics-Chemistry Society on 13th September 1916. He became an expert in spectroscopy, but he was even surpassed by his wife the spectroscopist Татьяна Фёдоровна Боровик-Романова (1896 Tomsk—1981) of Russian imperial family Romanow and their son low temperature specialist academician Wiktor-Andrei Stanislawowitsch Borowik-Romanow (Ви́ктор-Андре́й Станиславович Борови́к-Рома́нов, 1920 Leningrad-1997).

For eleven years, Cecil Reginald Burch FRS (1901 Leeds-1983) worked for Metropolitan-Vickers Electrical Company of former George Westinghouse's extension in English Manchester. The heavy electrical engineering proved to be just one of the platforms of Metropolitan-Vickers as they hosted such eminent inventors as Burch and Gabor. In 1928, Burch invented a diffusion pump with oil. Diffusion pumps with the pressures available down to 10^{-8} mbar were commonly used for high vacuum, especially in the American electronics industry between 1920 and 1940. They were displaced from the market by the pumps designed for ionic sputtering in 1958, on centennial of Geissler-Plücker's discovery. Plücker has already noticed the pressure drop in the vacuum tube due to discharge a century before its use in the pump: "Some gases react ... with platinum cathode and the resulting compounds are deposited on the walls. so, we approach ... the absolute vacuum." In 1902, Richard Smith Willows (* 1875) announced chemical compounds with glass in the walls of cathode ray tube; but the Norwegian aurora borealis expert Lars Vegard (1880–1963 Oslo) rejected his assumptions.[1364]

8.4 Conclusion

Of course, nobody can avoid the limitations imposed by nature itself. Thus, in 1977 C. Benvenuti reached 10^{-14} mbar in CERN, which for over three decades remains the lowest man-made vacuum available at room temperature. The modern failure to achieve an ever-better vacuum is like the similar stagnation between 1920 and 1950.[1365] Who will overcome it?

9 Plasma Waves or Corpuscles for New Aggregate State?

9.1 Beginnings of the Research of "Cathode Rays" at the End of the 19th Century

Cathode rays were the old name for the electron rays. In the second half of the 19th century, the experiments in the emptied tubes raised the question of the nature of the cathode rays. The second generation of researchers have greatly revived the exploration of cathode rays in the 1890s. The English mostly wrote about particles, while the Germans were the fans of waves.[1367] The nationally colored, even personal contradictions between researchers, became so sharp that the Germans even declared Crookes a charlatan.[1368]

9.2 Supporters of the Wave Model

In German language light of lighting is Licht while the light as lightweight is leicht. For French, lightweight is léger while the light of lighting is lumière. In other languages including Slavic ones there is even sharper difference between both with light of lighting more resembling something not at all lightweight but rather saint or even cosmic as the word svet means in Slovenian language. In Latin language lux and lucis as light of lighting is also far from levitas as leigtweight, and similar goes for the Italian luce. Therefore, the English language speaking folks including the Newtonians were convinced that the sources of light must output something lightweight, most probably the miniature particles, as soon as they abandoned their Latin speaking after Henrik VIII and his virgin daughter Elisabeth embraced the Protestant English language bible. The Germans doubted it because of their additional letter "e" in leicht which made their pronunciation basically different. The Catholic who preferred the Latin liturgy had even more doubts in lightweight sunshine even if waves of light could be imagined as something even lighter than particles. The quarrels between the proponents of waves and particles were therefore mainly the quarrels on semantic until the English language became the lingua franca of us all to pave the ways for the modern wave-particle quantum dualism.

Helmholtz's circle of supporters of waveforms of light, with the most prominent representative Hertz, found that the properties of "cathode rays" resembled the properties of light. For both they gave several striking similarities:

1) they are eliminated from heated and some cold surfaces

2) they are expanding linearly

3) they can cause fluorescence of glass

4) the magnetic field does not curve their paths much (soon proved to be false for cathode rays)

5) they spread in all directions with respect to the orientation of the illuminating surface (soon proved invalid for cathode rays)

6) the properties of light or cathode rays) generally do not depend on the characteristics of the heated lamps (or cathodes)

7) they transmit energy

8) they carry the momentum

The deflection of the cathode rays in the magnetic field was explained by the deformation of the "ether" in it. Spreading exclusively in the rectangular direction relative to the surface of the source was attributed to the electrical characteristics of the formation of "cathode rays".

9.3 Corpuscular Model and Crookes

For the proponents of the corpuscular model of cathode rays the main problem was the puzzle of their rectilinear propagation. In 1891 and 1892, Hertz pierced a thin layer of gold, silver, aluminium and various castings with cathode rays, which no known particles could up to date. Of course, the English partisans also had their own trumps, which Crookes was intending to pursue.

[1367] Carazza, Kragh, 1990, 4.
[1368] Frisch, 1972, 54–55.

Crookes was a physicist under Faraday's influence. Crookes' mathematical knowledge was inadequate, and therefore the leading British theoretical physicist Stokes was has often helped him.For Crookes, the interplanetary space seemed a giant emptied tube with the Sun instead of the cathode and the Earth's atmosphere as the glass surface of the cathode ray tube. If Newtonian light beam had some properties of the wave in addition to the particle properties, Crookes merged both opposing descriptions in a way that reminds us of modern quantum mechanics. According to Crookes, light consisted from particles should be in a vacuum, while light consisted from waves is in other media. Crookes did not yet know Hittorf's surveys carried out in Bonn in 1869.[1369] In 1876 and on 22 August 1879, at the Congress of the British Society in Sheffield, Crookes declared radiation for the fourth physical state of the matter:

"In studying this Fourth state of Matter we seem at length to have within our grasp and obedient to our control little indivisible particles which with good warrant are supposed to constitute the physical basis of the universe. We have seen that in some of its properties Radiant Matter is a material as this table, whilst in other properties it almost assumes the character of Radiant Energy. We have actually touched the border land where Matter and Force seems to merge into one another, the shadowy realm between Known and Unknown which for me has always had peculiar temptations. I venture to think that the greatest scientific problems of the future will find their solution in this Border Land, and even beyond; here, it seems to me, lie Ultimate Realities, subtle, far-reaching, wonderful."

In 1880, the Scotsman Tait and after him Goldstein announced that the wavelength of Crookes's supposed molecules was changed at high velocities of cathode rays due to the Doppler effect. Measurements did not confirm those promising forecasts.[1370] In the 20th century the astronomers had observed a similar phenomenon on celestial bodies as a redshift.

Even Stokes did not support the idea of corpuscular properties of light, since he was raised in a generation that repudiated a similar concept in the Newtonian version. But Stokes certainly directed his thirteen years younger Crookes to the idea of the fourth aggregate state of matter. Particularly fortunate was Crookes' presumption that in this state "matter passes into force" or energy, which specifically fueled German criticism.[1371] Germans just abandoned their own idealistic philosophy. Therefore, they refused Crookes' spiritualism. But their mutiny was in vain, resembling futile attempts of Leibnitz and Bernoulli to ignore alchemistic background of Newtonians two centuries earlier. Crookes' duality remerged into Bohr's quantum mechanics, while Crookes' fourth state transformed into Langmuir's plasma.

9.4 Waves and Particles at the Same Time

The results of the experiments conducted in Germany did not support British corpuscular theories. The leading German theoretical physicist Helmholtz predicted longitudinal waves in the "ether". For some time, it seemed that they were found in cathode rays. The seeking for longitudinal waves in the "ether" has initially directed Hertz experiments between 1887 and 1889, as he measured the electromagnetic waves which also many searched for several generations. In November and December 1895, Röntgen investigated the rays produced by the interaction of cathode rays with the glass wall of the vacuum tube. At first, he mistakenly considered them for the long sought longitudinal component of the electromagnetic wave in the "ether".[1372]

Crookes model of rays, which in some experiments have properties of waves, and in others, the properties of particles, was published in the late 19th century. Through the great physics door, it entered only in quantum mechanics with the material waves of Louis de Broglie after 1923. To Maxwell's contemporaries that duality would certainly seem unusual, and even more so to Grove and other older researchers. In 1842, Grove argued in favor of the success of Fresnel optics in a lecture before the Royal Institution (RI). Unlike most of his contemporaries, the "ethereal fluid" seemed to

him superfluous; the ordinary substance is enough to transmit vibrations in the space.[1373]

Hertz (1888), J. J. Thomson (1897), Einstein (1905), and others preferred to emphasize the connection of their discoveries with Maxwell's theory (1873) than to expose their differences in the description of the structure of the "ether" and electricity.[1374] The achievements of the Brits encouraged the Germans who returned to Brits even broader challenges with the ideas of Planck (1900) and Einstein's (1905) particle theory of quanta and photons as the Ljubljana physician Franc Derganc (1877 Semič-1939 Ljubljana) told his compatriots: "In 1900, Planck, a professor of theoretical physics in Berlin, examined the mathematical conditions in thermal radiations and found that the effect did not happen evenly, but in jumps, in shovels."[1375] So, the Slovenes soon read about the compromised conclusion of the dispute between the defenders of the waves and particles that is still in force today in duality of quantum mechanics.

10 Advanced Metrology

10.1 Development of Manometers

The better vacuum pumps needed more sophisticated manometers to measure their own void achievements. With McLeod's pressure gauge, pressure was determined indirectly from higher pressure measurements. Later researchers intensified the idea of indirect measurement. It turned out that gas pressure can be determined indirectly from completely different gas properties: thermal conductivity, viscosity, radiometric phenomenon and discharges. According to Maxwell's kinetic theory, the first two phenomena are independent of the pressure for average free pathways of molecules much smaller than the vessel; this does not apply to a vacuum.[1376] Viscosity, radiometric and electrical phenomena have already been used by Crookes in the middle of summer 1876 in parallel with McLeod's[1377] manometric pressure gauge for indirect pressure measurement. Nevertheless, useful manometers were developed only two decades later.

10.2 McLeod's Compression Gauge

The enhancement of pump and manometer's performance has undergone numerous improvements of flaps, connectors and traps in vacuum systems over the centuries. The professor of Physics and Chemistry in Paris, Regnault, measured pressures lower than the atmospheric with Hooke's wheel barometer, specially adapted for weather changes. The device was named "differential barometer".[1378]

Herbert G. McLeod was the oldest son of a London brewer; Joule was a brewer's son too, which made some strange connections between a good beer and good experiments in England. Herbert G. McLeod began his study of chemistry in 1855 under supervision of the professor George Frederick Ansell (1826-1880) at Panopticon in Leicester Square of West End London. In 1860, McLeod became Hofmann's assistant for chemistry at the newly established Royal College of Chemistry and at the Royal School of Mines in London. As assistant, he accompanied Hofmann, who returned from England to Bonn in 1863/64. In Bonn, they collaborated with Geissler and Plücker, the most important researcher of cathode-ray tubes at that time. After Hofmann's appointment as professor of chemistry in Berlin, McLeod returned to England as an assistant at the Royal College of Chemistry. He was already a famous researcher of discharges in a vacuum. In 1868 he was elected a member of the Chemical Society, and in 1871 he became professor of chemistry and physics at the Royal Indian Engineering College in Cooper's Hill and ten years later FRS. From 1868 he was also an advisor to the Oxford graduate, Marquis Salisbury, in his experiments at his home "Hatfield House", which he then inherited together with the title of Marquis. In 1869, Salisbury was chosen for the FRS, and in the same winter he illuminated the south wing of the house with Arclight. Then McLeod published a paper about a vacuum pump that Sprengel invented in London four years earlier. Salisbury was Secretary for India in 1866 and 1874. In 1873, Salisbury used McLeod's help to publish his research of discharges near mercury thermometers in Phil. Mag. Later in his eulogy upon Salisbury's death, McLeod summed up the report of Kayser, a professor of physics and director of the Physics Institute at the University of Bonn in Salisbury. Kayser praised Salisbury's discussion as the first proof that a low-temperature gas can radiate a clear spectrum of visible light. In 1878 and 1879 McLeod studied the dynamo and electric bulb and helped the then Foreign Minister Salisbury to illuminate the interior of his house with energy from his own hydroelectric power plant. Their collaboration, as an example of the highest position of science in the English society at that time, only ended between 1885 and 1902, when Salisbury served as the Prime Minister with some brief intervals out of office. Later, McLeod also investigated the effect of light on a type of rubber called ebonite. In 1915, due to health problems, he stopped active work. He spent the last five years in Richmond, Surrey County, where he died in 1923.

In the middle of the 19th century, mercury pressure gauges were only able to measure the pressure

[1376] Penning, 1937, 202–203.
[1377] DeKosky, 1984, 97–98.
[1378] Ganot, 1886, 159.

little below 1 mbar. Improved pumps required a better meter which was invented by McLeod[1379].

On 13. 6. 1874, McLeod pressed gas under mercury to the measurable higher pressure, from which, according to Boyle's law, the initial pressure was calculated with accuracy of a millionth part of mbar (Figure 10-1). The meter was connected to Sprengel's pump, a emptied receiver and a siphon barometer, which had a tube about 5 mm wide. The container of the measuring

Figure 10-1: The McLeod’s manometer.[1380]

device with a volume of about 48 cm^3 was narrowed at the top in a tube with a scale. Below it, McLeod connected it with a tube about 800 mm long connected to a mercury collector. The drainage from the reservoir was controlled by a tap and McLeod observed the movement of the mercury surface through the telescope.

In 1878 in the Parisian *Annales de Chemie et de Physique* William de la Rue and Hugo W. Muller, published a discussion about the combination of the Geissler pump with Sprengel’s pump and about the McLeod Vacuum-Meter. Edison read a translation of their discussion, and at the end of 1879, McLeod's manometer was purchased for his laboratory at Menlo Park.[1381]

Gaede investigated systematic errors in the measurements with a McLeod manometer. McLeod manometer with a rotary axis has been developed; it is still used today[1382] for measurements from 1 to 10^{-6} mbar.

10.3 Viscosity Pressure Gauges

The Australian physicist Sutherland tried to restore the research of phenomena in the radiometer in 1896 as Boltzmann’s fan and later predecessor or Einstein’s statistic explanation of Brownian motions. We call with Sutherland’s name an equation describing the change in viscosity with temperature. The following year he described the determination of the pressure in a vacuum by measuring the viscosity of the gas. His idea was used by J. L. Hogg at Jefferson Physical

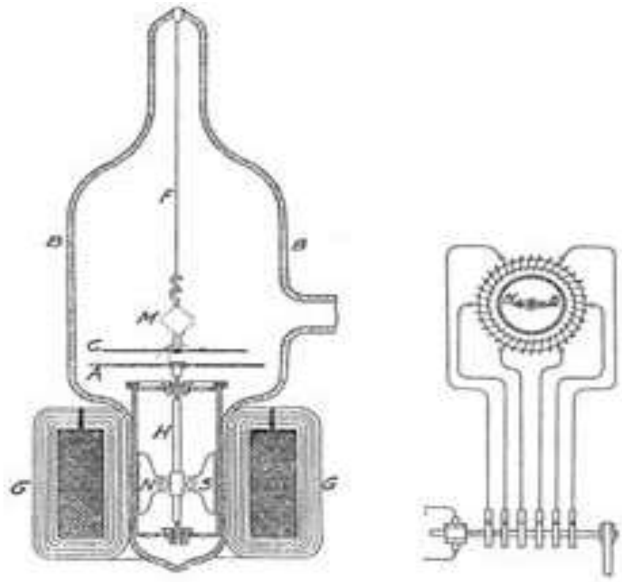

Figure 10-2: Dushman’s rotary cylinder meter.[1383]

Laboratory, Harvard University. Cambridge, Massachusetts in 1906, and seven years later by Langmuir, who also published the law of thermionic emissions. Langmuir used the fiber made of quartz, which fluctuated in gas. The

1383 Redhead, 1998, 1399.

pressure in the gas was measured by the contraction of the amplitude of the oscillation. In 1915, Dushman used Langmuir's description in a rotary cylinder for measurements of down to 10^{-7} mbar (Figure 10-2).[1384] In 1916, Langmuir described his mnometer version and high-vacuum pump.

Saul Dushman was born in a Jewish family in Rostov in Russia. They moved to Canada in 1892. He studied at Toronto, where he also received a doctorate in physical chemistry in 1912. He then went to General Electric (GE) in Schenectady, where he always worked closely with Langmuir. In 1917 he became a citizen of the United States. Between 1923 and 1925, he led research in the first General Electric lamp factory "Edison Lamp Works" in Harrison, New Jersey. From 1928 until his retirement in 1948, he was assistant director of the research laboratory GE. In 1949 he published a book on the scientific foundations of vacuum technique, which became indispensable in its field and was reprinted in an updated form in 1962.

Saul Dushman (* 1883; † 1954)[1385]

After his participations on Manhattan project, Jesse Wakefield Beams (1898 Belle Plaine in Kansas-1977) from the University of Virginia increased interest in viscosity manometers in the 1950s. It has been shown that the pressure in the vacuum can be determined by measuring the frequency of the rotating steel ball in the magnetic field. The frequency was about 1 MHz. Thus, in principle, it can measure down to 10^{-9} mbar. Later, the device was perfected by Johan K. Fremery in Bonn in 1985/86, but today it is used for measurements between 10^{-2} and 10^{-7} mbar.[1386] However, viscosity manometers were not widely used before the improvements of rabbi Ernst Steckelmacher's (1881 Mannheim-1943 Majdanek) son Walter Steckelmacher (1922 Mannheim-2006 Crawley in West Sussex) at the University of Sussex in Brighton in 1973.

10.4 Application of a Radiometric Measurement of Pressure

In 1907, Dewar reportedly cooled his radiometer to the temperature of the liquid air, hydrogen and helium. He thought that radiometer could measure the pressure more accurately than McLeod's barometer. He recommended radiometer for the detection of gaseous products of radioactive bodies.[1387]

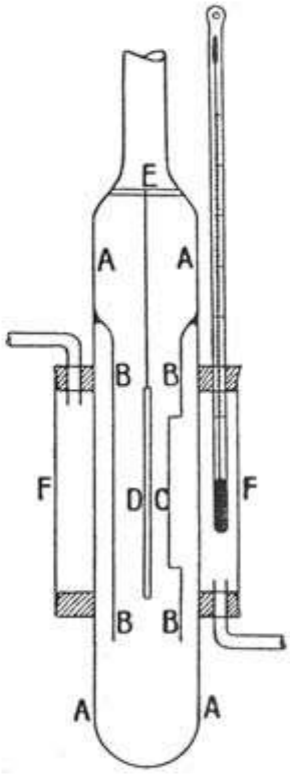

Figure 10-3 : One of Knudsen's pressure gauges on the radiometric phenomenon of 1910.[1388]

In 1910, at the University of Copenhagen, Knudsen composed a pressure gauge based on a radiometric phenomenon, which was not yet fully

[1384] Brush, Everitt, 1969, 124.
[1385] Redhead, 1994, 32.
[1386] Redhead, 1984, 32.
[1387] Dewar, 1927, 983–987.
[1388] Knudsen, 1910, 828.

understood in his time, although he roughly knew the dependence of the radiometer spinning on the pressure (Figure 10-3). Knudsen measured the total pressure in the room, not the partial pressures like McLeod's manometer, which, for example, could not measure the mercury vapor pressure. That is why Knudsen called his device an "absolute gauge" relating to the "absolute electrometer" described by Lord Kelvin earlier in 1855.

Knudsen measured the torque due to the transfer of the momentum from the heated molecules of gas on one side to colder molecules on the other side of the plates. In parallel to the heated metal plate, he placed a flexible metal plate as a handle of a torsion scales for measuring the repulsive force. The slabs were very thin, $2.5 \cdot 10^{-4}$ cm thick and 0.01 cm thick. Therefore, he observed the reflection of movement of the plate on a small mirror through the telescope.

The Polish knight **Marian von Smolan Smoluchowski** was born near Vienna where he studied at Stefan's class and promoted in 1894. He spent some time in the labs of Gabriel Lippmann in Paris, Lord Kelvin in Glasgow and Warburg in Berlin. He taught at Habsburgian universities. Between 1898 and 1913 he was a professor at the University of Lviv, then in Krakow, ultimately as a rector. In 1898, the mean free path in the kinetic theory of molecules explained the leakage of temperature (and velocity) between the surface of the plate and the gas. The occurrences were discovered by Kundt and Warburg in their measurement of diluted gas, placed between the plate of various temperatures at the University of Strasbourg in 1875. In 1905 and 1906, Smoluchowski described the Brownian movement, simultaneously and independently of Einstein in Bern and Sutherland. Smoluchowski used Boltzmann method. In 1907 and 1908 Smoluchowski explained opalescence with statistical theory. He was one of the most important advocates of Boltzmann's description of the second law of thermodynamics. He died in Krakow during the First World War, killed by a dysentery epidemic.

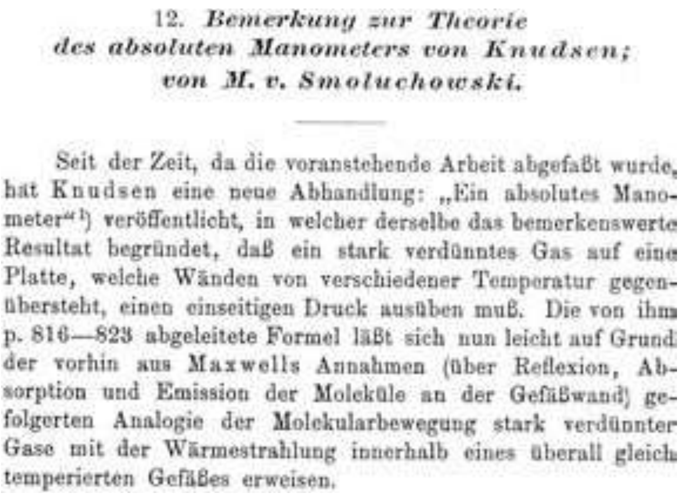
Knudsen's experiments, the distance between the plates was much smaller than the average free path of the molecules. During gas exhaustion, the reflecting force between the plates increases inversely proportional to the pressure up to a

Martin Knudsen was born on the island of Fyn. He studied at the University of Copenhagen and was a professor there between 1912 and 1941. Among his important contributions to vacuum techniques was his absolute pressure gauge reported on the 1st Solvay Congress. In 1909 and 1915 he supplemented Hertz-Knudsen's fundamental equation for the rate of evaporation. He published the first indirect proof of Maxwell-Boltzmann's distribution of molecules in terms of velocity. During the study of gas flow through narrow tubes, he discovered the law of diffusion of molecules and advanced his theory of radiometer.

Martin Knudsen (* 1871; † 1949)

ertain maximum, and then decreases proportionally to the pressure. Crookes and others noted similar findings in 1875 and 1876. However, Knudsen was the first to derive a simple equation for the proportionality of the repulsive force and pressure at the known temperature ratios. Thus, the size of the pressure can be determined from the measurement of the reflecting force between the plates. He made several manometers. The first one had a copper cylinder of 1.63 cm radius, the most convenient being a tube made of glass of thickness 0.41 cm, 1.4 cm wide and 2.95 cm high. He measured the temperature with a mercury thermometer. He pumped with Gaede's mercury pump to a pressure of $4 \cdot 10^{-3}$ or $5 \cdot 10^{-3}$ mbar of

hydrogen, oxygen or CO_2 atmosphere, which he also doublechecked with McLeod's manometer.
The Pole from the University of Lviv Smoluchowski immediately published the theory of diluted gas flow and described the operation of the Knudsen gauge with Maxwell's kinetic theory in In November 1910[1389]. He praised Knudsen's measurements, but criticized his theory which claimed that, in a narrow band above the edge, the higher pressure due to higher molecular velocities prevails over the pressure reduction due to a smaller free path at the barrier, thus increasing the overall pressure. The dispute continued the controversy of Maxwell and Meyer from the University of Breslau (today's Wrocław) against Irish researchers Stoney from Galway and his nephew, George Francis FitzGerald of Dublin, who claimed that the reflection between the radiometer's flaps was a superficial phenomenon. Maxwell and Knudsen after him correctly wrote that "the pressure due to the inequality of temperatures happens only close to the edges of the



12. *Bemerkung zur Theorie des absoluten Manometers von Knudsen; von M. v. Smoluchowski.*

Seit der Zeit, da die voranstehende Arbeit abgefaßt wurde, hat Knudsen eine neue Abhandlung: „Ein absolutes Manometer“[1]) veröffentlicht, in welcher derselbe das bemerkenswerte Resultat begründet, daß ein stark verdünntes Gas auf eine Platte, welche Wänden von verschiedener Temperatur gegenübersteht, einen einseitigen Druck ausüben muß. Die von ihm p. 816—823 abgeleitete Formel läßt sich nun leicht auf Grund der vorhin aus Maxwells Annahmen (über Reflexion, Absorption und Emission der Moleküle an der Gefäßwand) gefolgerten Analogie der Molekularbewegung stark verdünnter Gase mit der Wärmestrahlung innerhalb eines überall gleich temperierten Gefäßes erweisen.

Figure 10-4: Smoluchowski's criticism of Knudsen's absolute manometer.[1390]

plates, where the second derivative of temperature by volume is not zero".[1391]

Smoluchowski denied absolute validity of results of Knudsen's pressure gauge because the measurement of small temperature differences between the plates should depend on the material of the plate (Figure 10-4). However, Knudsen’s report on the "absolute radiometer" with force proportional to the pressure was adopted at the 1st Solvay Congress between in Brussels 30 October and 3 November 1911. Only Einstein from Prague and Hasenöhrl from Vienna participated there as the professors from Habsburg universities while Smoluchowski was not invited. In 1934 Gaede improved Knudsen’s manometer and preferred it as his best among all the meters (Figure 10-5). Today, it is used only in special noted circumstances.[1392]

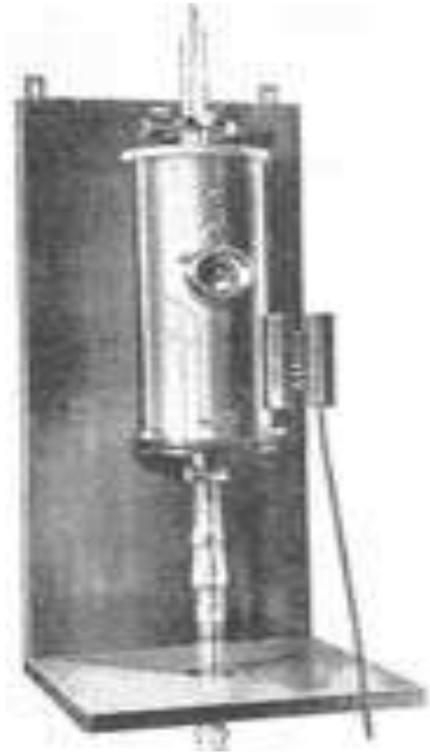


Figure 10-5: Gaede's Mol-vakuum-meter.[1393]

Knudsen and Smoluchowski continued the dispute over the absolute validity of the Knudsen’s gauge measurements. In 1911, during their fruitful debates, they also checked the operation of the pressure gauge on the heat conductivity, which is now known as Pirani’s gauge. Knudsen and Smoluchowski were engaged in friendly exchanges of opposite views, much unlike Smoluchowski’s predecessors at the Krakow university, Olszewski and poor burned Wroblewski.

Knudsen and Smoluchowski did not mention Stefan's measurements with diathermometer, but above all relied in measurements of the heat conductivity of Kundt and Warburg from 1875. They confirmed that down to 1 mbar thermal conductivity does not depend on the pressure in

Marcello Pirani was a Berliner of Italian descent. After studying at the Technical University of Berlin, he joined the German Physical Society, led by Max Planck and others. After his doctorate in October 1904, Pirani worked at the Siemens & Halske Lighting Factory in Berlin. From 1918 he was a professor at the Technical University of Berlin and after the founding of the conglomerate of German lighting firm bulb producers called Osram in 1919, he became the head of its research laboratories. The merged Osram followed the similar merged Telefunken of 1903 to provide better opportunities for German electronics. Pirani began to use the discharges in diluted gases for lighting instead of bulbs around 1930. In 1930, Pirani already produced lamps with 70% efficiency, and the following year Pirani's bosses started selling lamps with sodium steam and then the fluorescent lamps. In 1936, because of opposition to the Nazi authorities, Pirani went to England to join the General Electric Co. in Wembley, where his manometer was explored already in 1923. In 1953 he returned to Munich and two years later he returned to Osram in Berlin.

Marcello Pirani (* 1880; † 1968).[1394]

accordance with Maxwell's opinions. Knudsen has studied even lower pressures in which the average free path of the gas molecules greatly exceeds the size of the vessel. Kundt and Warburg measured gas between the plates of different temperatures and detected a temperature jump between the surface of the plate and the gas. That phenomenon could not be explained without the Smoluchowski's kinetic theory of molecules developed in 1898.

Pirani's invention ceased the annoying discomfort in the handling of McLeod's meters at Siemens & Halske in Berlin. There, Pirani utilized some 50 McLeods tools for his research of tantalum lamps. Each used about 2 kg of mercury; so, often there was a breakdown and toxic mercury was spilled everywhere on the floor of the laboratory: "I set out to develop a simple cheap vacuum gauge that could replace McLeod's. The project was not intended solely for the technique of rapidly detecting small pressure changes in a high vacuum but had a great health significance. It is known that it is becoming increasingly difficult to remove harmful mercury from the workshops." There was still no official recognition of mercury risks despite of old Hacquet's research, but the quicksilver pollution didn't please anyone anyway.

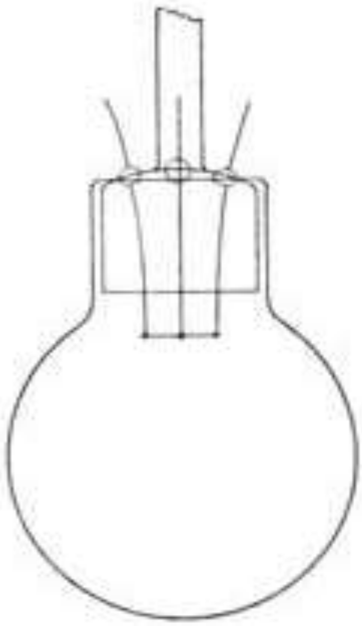

Figure 10-6: Voege's device for measurements of alternating current between 0.001 and 0.1 A, which determined the pressure through the conductivity of the diluted gases.[1395]

In June 1906, the pedantic Pirani as the best merge of Italian-German genes developed a device for indirect pressure determination in emptied receiver by measuring the thermal conductivity of the gas. The change in the electrical resistance of the heated conductor in the vacuum measured the heat

[1394] Redhead, 1994, 83.

[1395] Phys. Z. 7 (1906) 500.

lost by the gas throughput. so, he got a measure of pressure. A few months before Pirani, Willy (Willi) Voege in Hamburg and later Rohn developed similar pressure gauges using a thermocouple or thermistor whose output voltage is dependent on the pressure. Many newly developed devices replaced McLeod's manometer (Figure 10-6).[1396] In the 1930s, processes were developed for calculating the pressure from the measured thermal conductivity of the gas with a bimetallic thermometer or with evaporation rate in the Dewar's flask.[1397]

10.5 Mechanical Pressure Gauge (Manometer)

In 1929, the Americans from the university of California at Berkeley Axel Ragnar Olsen (1889 Halsingborg Sweden-1954) and his Ph.D. student Lester Larsen Hirst (* 1903) who later worked for Bureau of Mines described the pressure gauge on the capacitance to measure the pressures between 10 mbar and 10^{-4} mbar; so, they crowned the development of indirect pressure gauges. A similar mechanical manometer on the Bourdon's tube was already discussed by the professor engineer in Gdansk Hans Lorenz (* 1865 Wilsdruff west of Dresden in Saxony; † 1940 Sistrans by Innsbruck in Tirol) in 1917. Lorenz bended the pipe to measure the pressures from 1 bar to 30 mbar. Soon, mechanical pressure manometers measured a pressure down to 0.1 mbar.[1398]

10.6 Hot Cathode Ionization Meters

The lower pressure gauges were lagging somewhat behind the achievements of the pumps before the First World War. Useful manometers were only McLeod, Knudsen and Langmuir-Dushman's with a rotating cylinder.[1399] The last two were complicated, slow, and they did not measure enough low pressures. That's why they were looking for better solutions. Only the invention of the ionization gauge on the hot cathode has allowed the development of modern vacuum manometers. In 1909 at the Physics institute of University of Berlin Hahn and L. Meitner's collaborator Otto von Baeyer continued with Lenard's study of slow electrons from the Wehnelt's oxide cathode segments and showed that the triode can be used as a pressure gauge in a vacuum. Von Baeyer's research was rediscovered only by Redhead in 1984, so that for a long time the inventor of the ionization gauge seemed to be Oliver Ellsworth Buckley (1887-1959) who measured the vacuum in the Research laboratory of American telephone and telegraph company (AT & T Corp.) and of Western electric company with the frequency of ionization in hot triode in 1916 and published his achievement in highly popular Scientific American next year. Buckley sealed three platinum electrodes in a 6 cm long glass tube used for cathode, anode and a positive ion collector. In vacuum, the electrons fly from the cathode to the anode, so that the current does not flow to the collector. In the gas, electron collisions produce positive ions. They fly towards the reservoir, which is negative in relation to the cathode. Buckley measured a pressure-dependent ratio between the collector and the anode current in the range between 10^{-2} mbar and $5 \cdot 10^{-4}$ mbar. The results were confirmed by parallel measurements with McLeod and Knudsen manometers. A similar ratio was obtained in air, hydrogen and mercury. Since there were no movable parts in the triode, the vibration did not disturb the measurement. The ionization gauge was much cheaper, faster and simpler than its predecessors, as the pressure was determined by the galvanometer measurement. It was possible to measure the pressure of metal vapors, where older meters failed and gave up. Many people liked to study the miniature versions of the ionization gauge developed in the age of space flights.

Buckley's gauge was used until the middle of the 20th century for measurements down to 10^{-8} mbar and less. Among others, Paul A. Anderson in Washington achieved excellent results. He measured the contact voltage between barium and tungsten by Kelvin's method in 1935.[1400] At lower pressures, the measurement was interrupted by soft

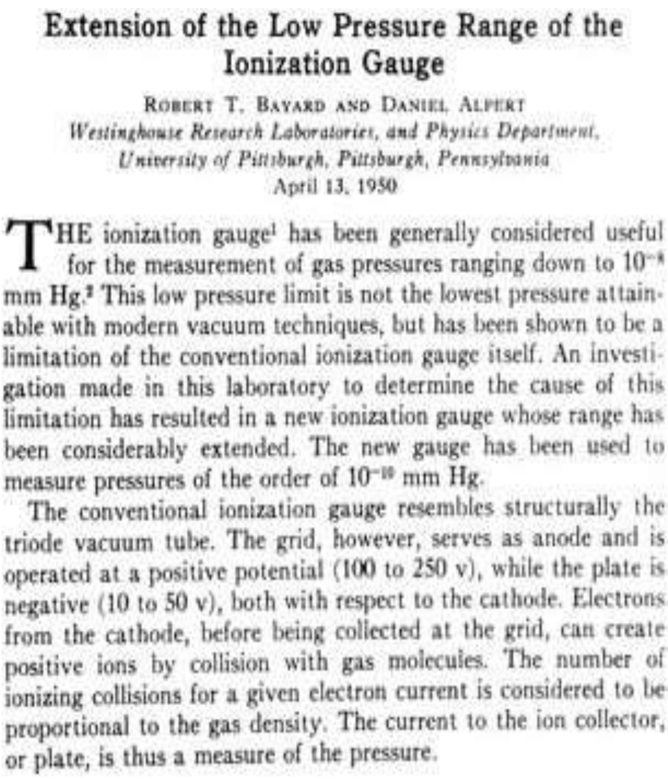
X-rays produced by the bombarding of anode with electrons which generated a constant pressure of about 10^{-8} mbar. The effect was known to manufacturers of cathode ray tubes but not to their related vacuum technology researchers before 1947. The independence of the residual pressure from the pressure was described by Edwin K. Jaycox and Howard W. Weinhart at o the Physical research department of Bell Telephone Laboratories, Inc., New York in 1931, and by Wayne B. Nottingham of the MIT (Massachusetts Institute of Technology) six years later, but their measurements were not used for the new form of ionizing gauge. Due to the independence of the residual current from the pressure, below 10^{-8} mbar there was no longer the linear dependence of the ion flux on the pressure at a given electron emission, which Dushman measured only between 10^{-2} and $4 \cdot 10^{-5}$ mbar.



Extension of the Low Pressure Range of the Ionization Gauge

Robert T. Bayard and Daniel Alpert
Westinghouse Research Laboratories, and Physics Department, University of Pittsburgh, Pittsburgh, Pennsylvania
April 13, 1950

THE ionization gauge[1] has been generally considered useful for the measurement of gas pressures ranging down to 10^{-8} mm Hg.[2] This low pressure limit is not the lowest pressure attainable with modern vacuum techniques, but has been shown to be a limitation of the conventional ionization gauge itself. An investigation made in this laboratory to determine the cause of this limitation has resulted in a new ionization gauge whose range has been considerably extended. The new gauge has been used to measure pressures of the order of 10^{-10} mm Hg.

The conventional ionization gauge resembles structurally the triode vacuum tube. The grid, however, serves as anode and is operated at a positive potential (100 to 250 v), while the plate is negative (10 to 50 v), both with respect to the cathode. Electrons from the cathode, before being collected at the grid, can create positive ions by collision with gas molecules. The number of ionizing collisions for a given electron current is considered to be proportional to the gas density. The current to the ion collector, or plate, is thus a measure of the pressure.

Figure 10-7 : Title page of Alpert's discussion Extension of the Lower Pressure Range in the Ionization Gauge published in Review of Scientific Instruments in 1950.[1401]

The problem was clearly set in Nottingham's paper at the 7th Physics Electronics Conference at MIT in 1947. The following year, the problem was re-addressed. In the summer of 1948, Alpert from

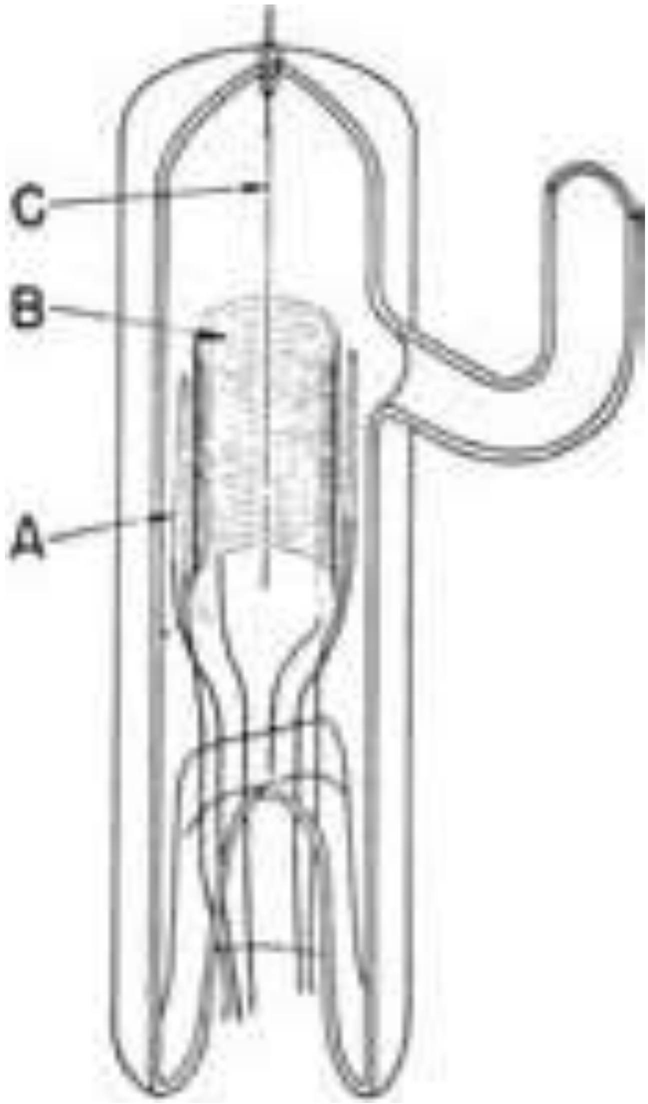


Figure 10-8: The original form of the Bayard-Alpert fiber ionization pump A, grid B and collector C.[1402]

Westinghouse's Research Laboratories asked Robert T. Bayard to investigate Nottingham's presumption. It was not necessary to wait much longer for the solution that Alpert introduced at the MIT in 1950. Instead of a cylindrical plate in the pump axis, he used an ionic collector from a thin conductor in the pump axis, which greatly reduced the flow of soft X-rays from the grid (Figure 10-18). By reducing the surface of the ion collector, it was possible to measure down to 10^{-11} mbar, which was the pressure due to the residual X-ray radiation flow on a thin conductor. At the same time, he proposed the use of purely metal valves for insulation of the system from pumps used at higher pressures, and the introduction of an ionization gauge as a main pump at low pressures. With this, the autonomous development of pumps and their

[1401] Madey, 1984, 145.

[1402] Redhead, 1984, 34.

meters merged into a single device after three centuries of separate developments. The competition between ultimate vacuum researchers and their measurers had shifted into cooperation. Something like the merging of magnetic and electric research after Oersted's experiment of 1819, or the merging of all known radiations in Maxwell's theory of 1873. The initially independent development of pumps and gauges finally combined into a single device after three centuries of competitions. The modern era just loves the universal devices like smartphones.

Paul Aveling Redhead has completed his physics education in Cambridge when he was twenty years old. By 1947 he was researching microwave cathode ray tubes for the British Ministry of the Navy, and then went to the National Research Council in Canada.

The collectors were hunting gas ions, thus lowering the pressure, which should be measured; this was of course a serious disadvantage of ionizing gauges. Alpert used the problem to improve the pump; the trouble provided advantage, just like the initially annoying sputtering on the glass walls of cathode ray tube. At the same time, Alpert proposed the use of purely metallic valves for insulation from pumps used at higher pressures, and the use of a low-pressure ionization gauge for the main pump[1403].

Daniel Alpert received his doctorate in physics at Stanford in 1941/42. In Westinghouse's laboratories he led the research team until he went to the Illinois University in 1959. The discovery of Bayard-Alpert manometer revealed that they had already reached 10^{-9} mbar in 1931, although such a low pressure could not be measured in those times. Alpert's ideas were developed in trap pumps that trapped gas molecules on surfaces within the system without removing them. The improvements soon reduced the vacuum limit from 10^{-8} to 10^{-11} mbar in the Redhead modulated meter from 1960 and the "extractor" of 1966 (Figure 10-8).

10.7 Cold Cathode Ionization Meters

Penning used a cold cathode at Philips in 1937. In a mutually perpendicular electric and magnetic field it received Towsend's discharge, the flow of which was often a nonlinear function of pressure. Penning's pressure gauge measures down to 10^{-6} mbar, and by improvements after the Second World War down to 10^{-12} mbar.[1404] Simple measuring devices of this type have been widely used as they surpassed McLeod's tools with their fast achieved, uninterrupted and nicely transparent results. Due to non-linearity and occasional errors, Penning's measurements were not very accurate, but they are useful for the industry for pressures between 10^{-2} and 10^{-7} mbar (Figure 10-9).

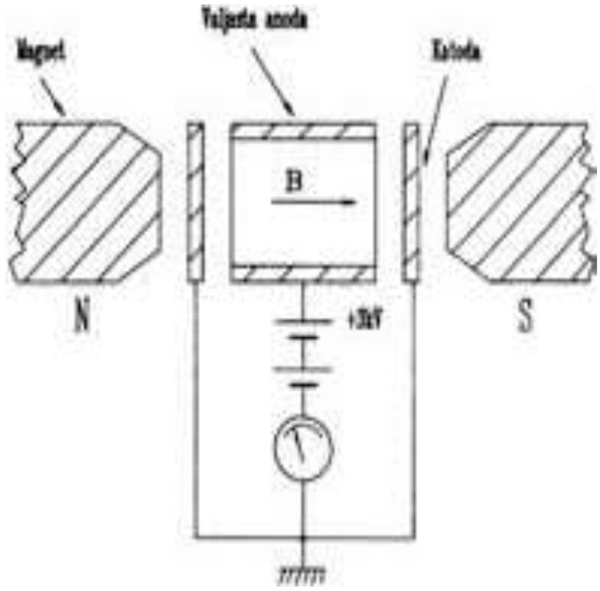

Figure 10-9: Schematic presentation of the Penning Cold Cathode ionization meter[1405]

For a Manhattan project of manufacturing atomic bombs between World War 2, Backus and colleagues developed ionization meters with the cold cathode. In 1943 or 1944, they invented a vacuum meter in the vacuum system with a mass spectrometer that began to sell at the end of the war. In the 1950s, it was found that the crossing of the fields corrected the defects of the Penning manometer, and the modified cathode model improved the capture of the electrons. The advanced manometers on the cold cathode could measure down to 10^{-14} mbar.

11 New Thin Films Materials: Sputtering, Condensation, Evaporation, Blistering

11.1 Experiments with the Sputtering of Metals and Thin Films in the 19th Century

11.1.1 The Discovery of the Sputtering of Metals in England

The thin films were noticed already after the explosions of the conductors through which Leyden jars were discharged. Englishman John Canton applied a metal conductor to glass, ivory and wood. After the explosions, he got the rainbow-colored coils, which were not as correct as in Priestley's experiments. The rubbing or electrification of the glass substrate did not affect the experiment. Priestley also experimented with explosions in a vacuum even though his pump was not the best. Unlike other explosions, his substances did not fly only in one direction.[1406] Thus, it would have been "possible" to notice the sputtering of metals in those times; but the amounts of dispersed material are small, phenomena are carried out on an atomic level, while the researchers were not able to observe the effects of electrical currents for a sufficiently long time before Volta's discovery of the electric battery at the beginning of the 19th century.

Nearly a century after Priestley, people were closely watching accompanying sputtering phenomena during the exploration of "cathode rays". The surface of the cathode is exposed to the plasma ions that strike atoms at the cathode. Grove first connected sputtering to metal layers on the walls of the glass tubes after discharge (Figure 11-1). Only a little after him Robida reported about his similar research.

In 1848, Grove and Gassiot jointly investigated the melting of platinum electrodes. The Parisian academician César Mansuète Despretz told Grove about the stronger inductors made in Ruhmkorf's Parisian workshop. With his advanced equipment in London, Grove was ready for a famous experiment, reported to RS immediately after the new year of 1852. The report, which paved the way for modern thin-layer technologies, was published on the first of April like a jokers' day. In fact, it was deadly serious. Grove first saw the accumulation of metal on the walls of the emptied tube after the discharge of the Ruhmkorff's inductor. The metal oxide shade was like that of a fashion photographer Frenchman Daguerre, who had just died at that time. Grove knew the photograph well, since he had been exploring it with Gassiot in a previous decade; recently Grove defended the "Daguerreotype" patent in England as a lawyer in court. Thus, Grove had a rare chance to use his legal and later judicial experience in experimental physics.

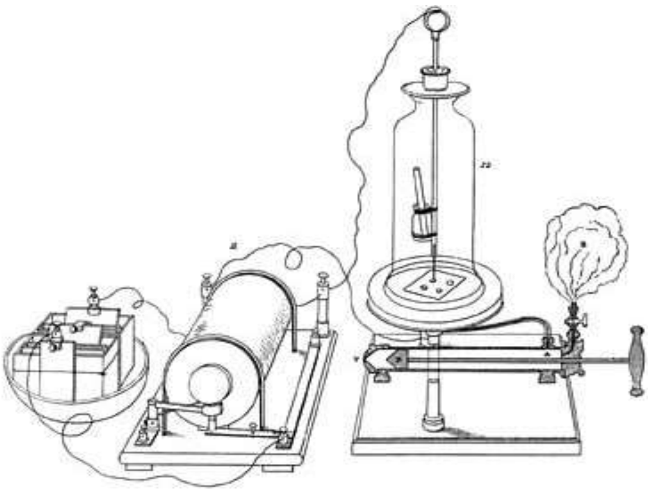

Figure 11-1: The schematic illustration of the device with which Grove investigated the discharges in gases, and in 1853 for the first time noticed the phenomenon of cathode sputtering.

When Grove switched the electrodes, he could completely remove the sputtered stain. There were no other metals in the sealed tube, so it was assumed that the cathode rays disperse the metal particles from the electrode, which are then collected on the glassy sidewalls (Figure 11-2). Grove observed his stain through an achromatic microscope at two hundred times magnification. He was aware that he is following a new phenomenon in which he will clear up an important similarity between the electrolysis and the discharges in a vacuum.

1406 Priestley, 1769, 218. Priestley, 1966. 2: 334, 359, unpaged appendix on the end.

Three weeks later in the addition to the initial discussion, Grove offered several explanations by analogy with Nobili's research of thin films produced in electrolysis.[1407] He has prophesied many interesting discoveries and proved that the actual transfer of atoms of platinum during discharge is a matter of fact. His important discussions were translated by Germans for their Ann. Phys (Figure 11-3).

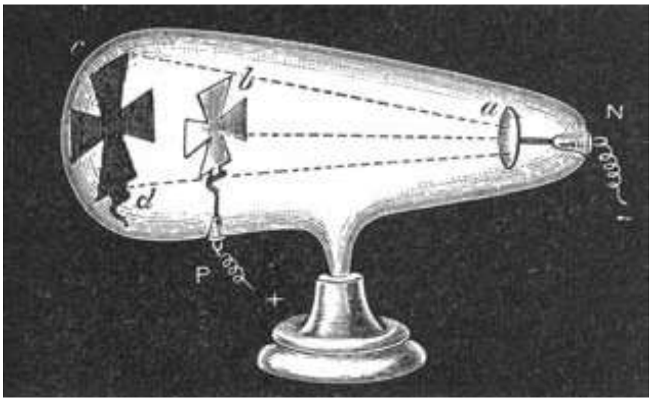

Figure 11-2: A shadow of "cathode rays" with a Maltese cross

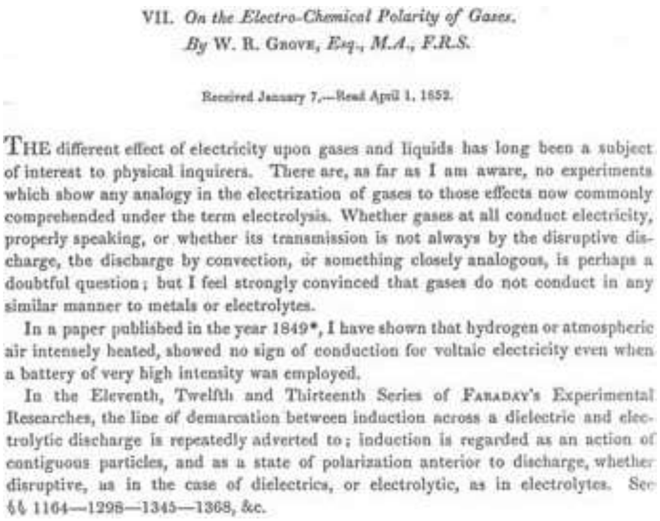

VII. *On the Electro-Chemical Polarity of Gases.*
By W. R. Grove, *Esq., M.A., F.R.S.*

Received January 7,—Read April 1, 1852.

THE different effect of electricity upon gases and liquids has long been a subject of interest to physical inquirers. There are, as far as I am aware, no experiments which show any analogy in the electrization of gases to those effects now commonly comprehended under the term electrolysis. Whether gases at all conduct electricity, properly speaking, or whether its transmission is not always by the disruptive discharge, the discharge by convection, or something closely analogous, is perhaps a doubtful question; but I feel strongly convinced that gases do not conduct in any similar manner to metals or electrolytes.

In a paper published in the year 1849*, I have shown that hydrogen or atmospheric air intensely heated, showed no sign of conduction for voltaic electricity even when a battery of very high intensity was employed.

In the Eleventh, Twelfth and Thirteenth Series of Faraday's Experimental Researches, the line of demarcation between induction across a dielectric and electrolytic discharge is repeatedly adverted to; induction is regarded as an action of contiguous particles, and as a state of polarization anterior to discharge, whether disruptive, as in the case of dielectrics, or electrolytic, as in electrolytes. See §§ 1164—1298—1345—1368, &c.

Figure 11-3: Grove's discussion on the discovery of metal sputtering.[1408]

In 1854 Faraday performed similar experiments and reported them to his friend Plücker in Bonn. Three years later, Faraday observed sputtering during the "explosion" of a metal wire in a vacuum, while at the same time thin films were studied by Plücker and the native Carniolan Robida. The first studies provided mainly qualitative findings on the duration of the loading of the thin layer and its position by the electrode.

William Robert Grove was at home in Swansea in Wales. He learned his basic from his domestic teachers, then attended the Brasenose College in Oxford and graduated in 1832. In 1835 he was called to the bar by the Londoner Lincoln's Inn. Between 1840 and 1847 he was a professor of "experimental philosophy" at RI, where he used Zn-Pt cells to illuminate his lectures. In 1846, he published a high-profile book on the Conservation of Energy. From 1853 he served as a lawyer primarily in technical cases and became a judge of the High Court in London. In 1872, the queen elevated him to a noble rank. Because of poor health, he abandoned his job and devoted himself to science in 1887. The basic principles of the fuel cell H_2-O_2 technology was published in January 1839 by the German professor in Basel Christian Friedrich Schönbein (1799 Metzingen in Swabia-1868 Baden-Baden) in Phil. Mag. Grove's HNO_3 battery was most commonly used in telegraphic devices until it was found to be hazardous because it leaked the dangerous NO_2. Grove's "gas voltaic cell" from 1839 was the predecessor of modern fuel cells. In it, the electrolysis process was turned upside down to bind oxygen to hydrogen for production of water and electricity.

William Robert Grove (* 1811; † 1896)

That is why Faraday directed Gassiot to explore the interactions of cathode rays with metals. Gassiot was a wealthy wine dealer, much like a younger brewer Joule; so, a good droplet again played a decisive role in the English discoveries of the time. On March 3, 1858, Gassiot proved that "small particles" were secreted into the side of the

[1407] Grove, 1852, 87, 89, 90, 94–95, 10; Bowers, 1998, 114.
[1408] Phil. Trans. 142 (1852) 87.

negative electrode, otherwise than in the voltaic cell; therefore, the light of the inductor's discharge cannot in any way be derived from the emanations of metal particles.

Other than in Davy's and other studies of discharges, in Geissler tube, the particles of metal are sputtered from the negative electrode, and they do not reach positive electrode at all. According to Gassiot, sputtering of the cathode from platinum cannot cause light phenomena in the discharge of the tube, since it does not have the same direction in space. He prevented the formation of metal sediment on the glass wall around the cathode of the emptied tube, in front of which he placed an additional open tube with a smaller diameter. The cathode was then cold and undamaged. Crookes found that thin films cannot be easily mechanically separated from the substrate or obtained by compression.[1409]

Gassiot was a wealthy wine merchant and amateur scientist. In the 1860s he supplied Maxwell with the devices needed to prove the equivalence of electromagnetic and light velocity. Gassiot was the vice-president of the RS. Among the first in England, he acquired Geissler's glow discharge tube filled with dilute gas and produced his own inductor.

11.1.2 Measurements in Germany and Austria

11.1.2.1 Plücker in Bonn

Plücker introduced a mathematical spirit in experimental research and described a vacuum as an unattainable limit. After exploring discharges in diluted gases, at Christmas of 1857, and again few months later, je declared that during discharge he could "glue, silver or cover the glass walls of the discharged tube with galvanic flow". Gassiot's measurements confirmed his opinion that the particles of metal originate only from the negative electrode. On the inner wall part of the closed emptied glass containers, we always find the same type of metal as at the negative electrode. The wall of the vessel is so dark due to the accumulation of an extremely thin layer of platinum from the cathode.

Julius Plücker from Elberferld in Prussia studied in Berlin and Paris. In 1825 he received his Ph.D. and became a private assistant professor of mathematics and physics in Bonn, and in 1828 he was an associate professor there. Despite criticisms that the university already has enough mathematicians, Plücker attracted many students with his mathematical treatment of physical problems. In 1834, Plücker received a regular full professorship in Halle, and in the following year he became a professor of pure mathematics and mechanics in Bonn. After the death of his professor of mechanics and experimental physics K. von Münchow, he also temporarily took over the cabinet of physics. Since the Prussian ministry could not obtain a suitable professor of physics for a long time, there was one of the most interesting combinations in the history of science: the mathematician Plücker lectured in a full course of experimental physics the summer of 1842 and began his research work. Thus, in Plücker's networks, the important research in geometry and experimental physics challenged each other. Since he did not have a laboratory for students, he used to invite students to his home-based laboratory, where Hittorf from Bonn, later professor in Münster, assisted him for some time. After Plücker's death, Clausius took over Plücker's chair and the physics laboratory in Bonn and Hertz did the same later to his own perish.

Julius Plücker (* 1801; † 1868)[1410]

[1409] Gassiot, 1863, 134, 137; Plücker, 1858, 67; Hittorf, 1869, 197–198, 210–211; Hittorf, 1884, 126.

[1410] Sparnaay, 1992, 62.

The charged sputtered particles collected on the walls of the vessel in clear forms or mixed with the gas particles. Plücker curved their trajectories with a magnet, and only blacked the individual parts of his cathode ray rube. He reported particularly beautiful mirrors from platinum on a leveled basis.

He noticed that the particles from the heated platinum cathode sputtered toward the anode. Therefore, the interior of a sufficiently small discharged tube is covered with a fine mirror in which one can chemically prove platinum. He altered the admixtures of gases in the emptied tube and found that thin disks did not form disruptions in the fluorine and boron. He had a very thin layer of platinum blue, like a thin layer of gold. He got a nice mirror with a zinc electrode which almost certainly impressed the Bonn native beauties. He investigated the formation of thin films of different thicknesses and lengths at the electrode in the tube.[1411] Without knowing Grove's research,[1412] he announced that the bombarding with cathode ray can be used to sputter very thin metallic films:

"The wall of the container is blacked by the fine metal particles. The layers of large thickness make fine metal mirrors. They are like the fine particles of gold, which Faraday studied in 1857. With zinc we get a nice mirror on the parts of the glass tube opposite the zinc electrode. This mirror has shaded shadowed boundaries in the pipe. Thus, with a new series of experiments, we can learn about the new optical characteristic of thin sputtered metal.

The blackening of glass is reduced if the thin wire of the negative electrode is replaced by a thicker one. Then there will be no additional excessive heating electricity. The stronger flow of metal particles from the thin wire formed as negative electrode is not only due to the smaller surface, but also to the greater heating due to which the electric current is more concentrated."

Geissler sometimes only partly inserted the platinum electrode inside of the cathode ray tube. He observed the sputtering only on part of the inner wall of a thin glass tube within the electrode's reach.[1413]

In 1877, Wright, a professor of experimental physics at Yale, designed Plücker's similar method for applying thin metal layers, which we still use today.[1414] Four years later, he became a member of the National Academy of Sciences (NAS). The dispersion of plasma ions was no longer just a damaging phenomenon that destroys cathodes and pollutes plasma, for example, in fusion reactors. We can use it for cleaning and etching surfaces of solids, for the application of thin films and for surface analyzes. Once annoying occurrence became a profit of its own, as it frequently happens in applied sciences resembling the bothering moulds which suddenly transformed into Fleming's antibacterial properties of penicillin.

11.1.2.2 Hittorf in Münster

Plücker mainly investigated the spectra of diluted gases, while his student Hittorf in Münster was interested in the electrical conductivity of gases at low pressures and higher temperatures. At the distance between the electrodes 1 to 2 mm, he glowed a platinum electrode 1/2 mm thick. The metal from the cathode sputtered the mirror on the glass.[1415]

The sputtering of the platinum from the electrode to the glass less disturbed the measurement in larger tubes like Ruhmkorff's 40 cm long spark at the exhibition in Paris. In the spring of 1867 Plücker experimented there among Parisians, and Hittorf did the same in September.[1416] In 1884, Hittorf found that most of the metals sputter from the cathode before they reach their melting point. The platinum is dispersed when the spiral of the conductive stream in the tube receives the color of the yellow glow. For 2 mm thick cathodes made of aluminium, Hittorf used as many as 1000 Bunsen batteries connected at a pressure of 2 to 3 mm Hg. The pulsating discharge covered a glass wall with a thick gray mirror in a beautiful marine green color within a few seconds.

If the cathodes from aluminium were not totally sputtered, their surface became rough, full of thin

[1416] Hittorf, 1869, 202, 210.

tips. The anode remained unchanged. Hittorf described the sputtering of usable mirrors made from copper. Unfortunately, the marketing of such expensive mirrors was initially not available, so researchers treated them a disruption phenomenon. Only a few Prussian blue-haired maids could have dreamed of such mirrors as their beauty tools.

Unlike Puluj and other contemporaries, Hittorf has not yet distinguished between the vapor deposition and sputtering. He erroneously used the term "vapor deposition" for the ionization sputtering in which each ion spills a certain number of atoms from the cathode, which are then loaded onto the vessel wall. The mechanism of sputtering was explained only half a century after its discovery, and another half of the century passed before the first quantitative models were proposed.

11.1.2.3 Robida in Klagenfurt

The most important physicists of the Slovene genus of the late 19th century, Stefan and Klemenčič, did not publish papers about cathode rays, although Stefan encouraged the efforts of his Viennese assistant Puluj. Simon Šubic published more about Geissler's tubes. Crookes influenced even the research of Zoch in faraway Sarajevo. The most important Slovenian researcher of cathodic sputtering was Stefan's Klagenfurt gymnasium professor and principal teacher, the Benedictine Karel Robida. He considered that the vacuum is a complete electrical insulator, although a total vacuum cannot be achieved.[1417]

Robida was unable to perform difficult experiments without proper pumps and seals, since in 1857 he had not yet acquired Geissler's cathode ray tube. That is why he referred to the experiments of Berliner jeweller Riess from 1838, who had very poor reputation among the Viennese researchers even if he became the first Jewish member of Berliner academy in 1842 and a father-in-law of Quincke two decades later. Robida did not mention similar surveys of Berliner Professor Erman announced in 1802. Both considered that only the magnetic properties of a natural magnet are permanent, while the electrical properties are not, as each substance is discharged over time.

Three decades before Hertz, Robida published qualitative measurements of the electromagnetic wave detection from a charged electroscope of Fechner and from the dry cell of Zamboni. Grailich's assistant at the Viennese Physics Institute, Blaserna could not repeat Robida's detection of electromagnetic waves with the Fechner's electroscope after rubbing a metal plate with a violin bow in 1858. Therefore, he rejected the supposed discovery of electromagnetic waves, and Grailich was offended by Robida's bizarre experimentation. Stefan did not answer, although he closely collaborated with Grailich as a Viennese assistant professor of mathematical physics and assumed Grailich's position after Grailich's sudden death.

Karel Lucas Robida from Mala Vas (Small village) no 2 near Ježica, now part of Ljubljana, studied at a gymnasium (Grammar school) and then visited Lyceum in Ljubljana until 1824. In 1829, he joined the religious order of Benedictines and after the ceremonies accepted the religious name Karel in the Benedictine monastery St. Paul in the Labotin valley, just at the then Carinthian regional and Slovene linguistic border. In 1830, Robida completed his theological studies and passed the exams for the teacher. Between 1807 and 1871, the Benedictines led a Lyceum and then a Gymnasium in Klagenfurt. From 1830 to 1845, Robida taught at the Gymnasium in Klagenfurt, and after Kobentar's death, he took up a chair for physics on the Lyceum in 1847. In Klagenfurt, he lectured on physics and mathematics for twenty-seven years, until his retirement in 1874. He published a total of ten papers about physics and a first book on physics in the Slovenian language in 1849. He published also theological, popular scientific and practical scripts, mostly in the Slovene language.

With his vibration theory of longitudinal waves of the electrons, Robida explained the phenomena in the discharge of the fifty elements of the Grove's cell through the platinum electrodes in the exhausted vessel. As the first Slovenian researcher, he sputtered a pin-point electrode from platinum and "made a white round spot from a giant number of platinum grains, which at the higher temperature

[1417] Robida, 1857, 5, 11, 12.

captured the plates ... The stain was whiter if the platinum particles lay closer to each other".[1418]

Robida published his paper five years after Grove's discovery of metallic cathode sputtering and several months before Plücker's descriptions;[1419] it is therefore desirable to read the Robida's description of experiments:

The deposited excreted substance forms the ring of a very correct shape on the negative plate by the positive (electrode). The center of the ring is the projection of the tip to the plate. That occurs both in the horizontal and the vertical position of the panel, therefore there is considerable focusing of the motion of matter from the positive towards the negative pole. After the discharge of the fifty elements of the Grove cell in a heavily exhausted air, while the platinum plate is positive, and the tip is negative, at first there is a bluish, completely round stain immediately under the Nobili's coils.[1420] The same stain is observed (after discharge) in the atmosphere, but they are closer to each other, have a smaller diameter and much less vibrant colors. When we turn the pole, the plate receives from the positively charged peak (electrode) a white circular stain, composed of the huger number of platinum grains that have taken on the plate at higher temperature. In the diluted air the stain became much larger than in a (total) vacuum. The (electrode) tips of iron, silver, and copper give similar results. Positive electrodes from silver and copper plates show very distinct indentations. The tip and plate made of copper give the arc in beautiful green light. If both tips are of the same metal, only the positive will glow throughout their length.

Neeff experimentally determined which pole emits light and which emits heat. By using a microscope, he distinguished two kinds of light. The first consists of the intangible small points of vibrant shine, which are stuck on platinum when the plate or tip of the platinum conductor is a negative pole. The points of light are very thin tips of rough surfaces whose light in electric power produced by friction is called light spike. Neeff called another type of light a fire that appears in a weak violet color. It appears on the tip as a glossy envelope and lies in its plane on the plate. A similar light phenomenon also moves from a negative pole; the least it is, the more it is white. The more pronounced it is, the more it turns purple. Because light is emitted exclusively on the negative pole, according to Neeff, heat is eliminated primarily on the positive pole. The Parisian mathematician Moigno argued that the source of light is most evident when using Ruhmkorff's inductor. The platinum spheres are poles half of the induction current in the vacuum. The negative sphere is bright and relatively cold, and the positive is dark and relatively warm.

Christian Ernst Neeff (Neef, 1782-1849) was a professor at Frankfurt am Main until he passed away. In 1839 he compiled a standard short circuit breaker for small inductive coils. It operated on the same system as a hammer with an electric bell. Neeff mainly researched in electromedicine. According to Goethe's example, he developed the cooperation in natural science, technology and industry in Frankfurt since 1824. He was a Doctor of medicine and a physician in the city hospital, director of the botanical garden, co-founder of the Society of German Naturalists and Physicians, the founder and first president of the physical society.

Robida used his and Grove's somewhat obsolete wave (vibrational) theory to explain the thermal behavior of electricity. The intense fluctuation of the flow sources converges into a small number of elementary waves that carry particles unsuitable for electric oscillations. Therefore, there is a positive electricity of heat fluctuations (vibrations) and negative electricity of light fluctuation.

The vibrations of particles of the body causes heat. From here we have heat acquired by friction, collision, impact. We've already seen thermal fluctuations causing the electricity. On the contrary, we observe electric vibration, which causes heat fluctuation. When melting electrical conductors, electric vibrations with heat fluctuations increase the volume and the motions of particles. The temperature of the conductor is below the melting point and the already melted surface layers are reflected. It seems that these layers accumulate the substance only on the negative electrode, and they are taken it away from

[1420] Nobili taught physics in Archducal Museum of Florence.

the positive electrode. Moigno did not notice the warming of the positive electrode, nor did the flying away of the oscillating particles in the direction of the oscillation which depose on the negative electrode.

The fluctuation of light in which the less intense light stimulated electrical vibrations was noted in electrochemistry. Because of electric oscillation, the oscillation of light is directed towards the negative pole.

Light waves arise from electric elemental waves and cover the surface of the slab of negative pole and wrap the tip of the negative pole. The formation of coils or round spots on the electrode allegedly confirms that Robida's explanation of the electric current.

Vibrations-Theorie der Elektrizität.

Von Professor Karl Robida.

Figure 11-4: The title page of Robida's discussion of the vibrational (wave) theory of electricity, printed in the 1857

If one electrode is a plate, and the other one is conic, then the center of the ring coincides with the extension of the tip. In the diluted air the stain on the positive plate is vivid and wider than the atmospheric air. The slab on the negative plate consists of platinum grains and is greater in the diluted air than in a vacuum.

Light expands easier in the rarer air, while heat expands easier in the denser air. The stain is whiter the as parts of the platinum lie closer to each other and gets more purple as the fluctuation of light increases..." (Figure 11-4).[1421]

In his Grammar School Report Robida observed cathodic sputtering, since the material from the negative tip was deposited on a positive electrode.[1422] Due to Grailich's criticism of Robida's work, there was no special support of Robida's claims because Ettingshausen's son-in-law Grailich acted as a leading representative of the distinguished Viennese institution. Robida's subsequent atomism and, basically, his controversy with Clausius in the famous mathematical-physics journal of Leipzig, had a far greater impact , which certainly influenced Robida's high school student Stefan.

11.1.2.4 Reitlinger and Wächter in Vienna

Stefan's chief executive, Ettingshausen, acquired the Geissler's glow discharge tube filled with dilute gas for their institute very early.[1423] He noticed that the color of the vacuum in the cathode ray tube depends on the type of gas contained. In the narrower parts of the tube, he detected the interrupted light, and in the wider parts of tube there were fine nice layers.

Already Plücker's research has shown the dependence of the spectrum on the type of gas and on the thickness of the cathode-ray tube. Ettingshausen commissioned Reitlinger to investigate this phenomenon and handed him several cathode-ray tubes and Ruhmkorff's inductor. During his measurements, Luka Žerjav helped Reitlinger. One finding of a multi-year research was that the vacuum was an isolator for light and heat, which Huygens and other early pioneers already noticed in their less sophisticated ways.

In 1861, Reitlinger adjusted his optics so that he could observe two spectra from various Geissler's cathode ray tube and compare them with each other. He confirmed the assumption of the metallic nature of hydrogen and noticed very beautiful layers, which he called "pearls". He influenced the

distribution of light and dark layers by a magnet (Figure 11-5).[1424]

> The Austrian **Edmund Reitlinger** first studied mathematics and astronomy, and then he matriculated at the faculty of law. In 1855 he studied physics at W. Weber's class at the University of Göttingen. In 1849 Weber returned from Leipzig to Göttingen after twelve years of exile because he signed a political petition. In 1858, Reitlinger received his doctorate at Ettingshausen's lab in Vienna and became the assistant professor at the Viennese Physics Institute next year. Reitlinger expanded his lectures on the history of physics, inductive logic and the theory of physical research, when after Mach's departure to Graz, he took over his Viennese lectures for medical students. In 1863 he was a candidate for an associate professor in Graz. In 1865, Mach again recommended him successively for von Lang's successor in Graz, and in the following year Reitlinger became a professor at the Viennese Polytechnic and at the Technical College in addition to Victor Pierre and the Bohemian Finger, who earlier taught at the Higher Real school in Ljubljana between 1870 and 1874.

On July 24, 1862, Reitlinger and Luka Žerjav presented a discussion that crowned more than a year of their ongoing experiments at the Physics Institute. [1425]

They found that the layers were denser at higher voltages, that the spots of stains depend on the cathode used, that the layers are lighter in a higher vacuum, and the width of the layer depends on the type of gas in the vacuum and the length of the tube.[1426]

The light and dark layers of discharges in the cathode ray tube have already been described by the Dean of the Faculty of Natural Sciences in Marseille, Morren, in a letter to Moigno, which was also translated into German. The dean of the Bordeaux faculty of sciences Jérémie-Joseph-Benoit Abria (1811 Limoges-1892 Bordeaux) assumed that the layers in the vacuum cathode ray tube were mechanical and not an electrical phenomenon. Reitlinger and Žerjav noted that the layers in Geissler's electrical glow discharges in the tube of diluted gases caused differences in electrical conductivity.[1427]

Über Schichtung durch Entladungsschläge der Leidner Batterie.

Von **Dr. Edmund Reitlinger,**
[illegible]

und **Luka Žerjav,**
[illegible]

(Vorgelegt in der Sitzung vom 24. Juli 1862.)

Als die Schichtung des elektrischen Lichtes vor einigen Jahren viele ausgezeichnete Physiker beschäftigte, richtete Morren, Decan der naturwissenschaftlichen Facultät zu Marseille einen hierauf bezüglichen Brief an Abbé Moigno, der in dessen Journal Cosmos ¹) veröffentlicht wurde. Er schreibt die Schichtung vor Allem der Unzulänglichkeit (*surtout a l'insuffisance*) des gasförmigen leitenden Körpers zu, durch welchen der Strom geht. Das Phänomen der Schichtung selbst besteht nach seiner Ansicht in Induction und Seitenentladung gegen benachbarte leitende Körper. Um seine Ansicht besser verständlich zu machen, führt er Wahrnehmungen an, die man an Dräthen macht, durch welche mächtige Entladungen statischer Elektricität gesendet werden. Wenn er Dräthe aus Platin, Silber oder Gold nahm, so wurde der Drath durch starke Entladungen zerstäubt. Morren schrieb dies Seitenentladungen zu, die der grosse Leitungswiderstand veranlasste. Da er auf Papiercylindern, mit denen er die Dräthe umgab, geschichtete Spuren sah, so glaubte er in dieser Erscheinung die Grundlage zur Erklärung des geschichteten Lichtes zu erblicken. Selbst wenn die Zerstäubung des Leiters durch seine Dicke verhindert wurde, nahm Morren geschichteten Metall- oder Oxydstaub in dessen Nähe, z. B. in der Nähe einer Kupferkette wahr, wenn sehr starke Entladungen von Leidner Batterien hindurch gingen. Diese Spuren

Figure 11-5: The title page of Reitlinger and Luka Žerjav's paper[1428]

Reitlinger harshly criticized Riess's assumption of the continuous translation of dark layers and the discontinuous translation of light layers in the emptied cathode ray tube.[1429] According to Reitlinger, due to the low conductivity of the bright layers, they heat up and, therefore, shine, as shown by experiments with spectral analysis. Riess, however, considered that the difference in brightness was due to the different density of gas in the cathode ray tube.

Reitlinger did not explain the formation of the substance layer in the cathode ray tube.[1430] Puluj considered that all the particles of different masses in the lighter part of the cathode ray tube are directed away from the cathode, while in the dark field they move in any direction. Since they have

the same energy in equilibrium, there are three times more particles in the lighted part of the cathode ray tube than in the darker part.[1431] So, the reason for the lower luminosity is the smaller number of particles and not the smaller number of collisions, as Crookes believed.

Auguste Morren was the first professor of physics working in the physics and chemistry laboratories of the Faculty of Science in Marseille, founded in 1854. He was the pioneer of spectroscopic analysis. In 1859, he made the first direct hydrocarbon analysis, although discovery was attributed to three years later Bertholet's exploration. Morren's and Abria's discovery was independently reiterated by Quet, rector of the Academy in Besançon, and at the same time by Grove in 1852. Gassiot also noticed the layeringy in the continuous discharge strong battery voltages. In 1861 he assumed that the fluctuation depends on the resistance of the medium. In 1856, Riess distributed the discharges among the continuous and discontinuous according to the conductivity of the media. Quet and the French Séguin distinguished the positive and negative layers. The railways technician Séguin was Montgolfier's grandnephew and student which stimulated the prestige of his ideas. In 1862 the physicist at the University of Geneva, de la Rive, measured that the dark space in the cathode better translated electricity than the light space. The professor at Leipzig and editor *Ann. Phys*. G. H. Wiedemann and Richard Rühlmann, professor at the Chemnitz Gymnasium, explained the layers in cathode ray tube with high speeds needed to enable the translation of the particles of gas. The discharge layers in the diluted gases were further investigated by Hittorf (1869) and Crookes in 1878-1879.[1432]

Riess dealt with the translation of gases by analogy with translations in solid matter in a contradiction with then mainstream kinetic theory based on behaviour of gases. He advocated the one-fluid theory of electricity, while the Ettingshausen's school of both Stefan's and Reitlinger's direction preferred the hydrodynamic analogy. Thus, the controversy between Riess and Viennese physicists lasted more than two decades and marked three generations of researchers: Ettingshausen, Reitlinger (1861-1862) and finally Wächter (1882). Reitlinger rightly criticized Riess's theory of anodic scattering and figures, which was discovered in 1784 by Lichteberg, a professor at Göttingen. Reitlinger argued that cathode sputtering is essentially different from anodic sputtering. Hittorf's and Wächter's (1882) idea of cathodic dispersion as evaporation of the cathode proved to be ineffective, just as Berliner's (1888) cathodic dispersion assumption about the evaporation of adsorbed gas, which extracts cathode particles with it.

Johann Puluj was an assistant in the c. k. Maritime Academy in Rijeka. In 1877, he habilitated at the University of Vienna and worked as a private assistant at von Lang's laboratory. He was also Kundt's assistant in Strasbourg, then a professor of physics and electrical engineering at the (German) Technical College of Prague. In Prague, he was mainly concerned with the fluctuation under the influence of his senior colleague Mach.

The Habsburgian researchers of vacuum discharges Reitlinger, Puluj and Wächter supported the claims of some English (Grove, Gassiot) and Westphalian researchers (Plücker, Hittorf), which were opposed to Englishman Crookes and the Berliner Riess. Of course, all the researchers relied on Faraday's authority.[1433] Reitlinger supported Grove's theory of the cathode-ray layer as developed by Gassiot in his Bakerian lecture in 1858. The contrary theory was published by French Gaugain, who considered that the speed of electricity was not constant, but it depends on the coefficient (refractive index), conductivity, the cross-section and the length of gas captured in cathode ray tube. Gaugain's theory was supported by Riess.[1434]

After Reitlinger's disease and death, Friedrich Wächter continued research at his institute. He experimented with aeronautics and meteorology, led the Natural history museum, and collaborated with his Viennese TU classmate the officer Philipp Hess as a technical council in Technical Officer of the Technical Military Committee (technische Räth

[1431] Puluj, 1889, 242.

in Technische beamte des Technische Militär-Komitees) specialized in electricity and military aeronautic balloon department (Militäraeronautischen Anstalt) from 1888 until the outbreak of war despite Wilhelm Kress' opposition.[1435] He endorsed Puluj's criticism of Crookes' (1879) idea that the average free path is equal to the length of the dark region in the cathode-ray tube. The critique was based on Stefan's determination of the average free path. Wächter advocated a dual-fluid theory of electricity, in which positive and negative electricity are qualitatively different. He studied in detail fourteen differences between anodic and cathodic sputtering, while criticizing Riess and others who equated both phenomena. Thus, the dispute between mono-fluidic (of Franklin, Riess, Thomson) and two-fluidic (of Schuster, Wächter) theory of electricity has dragged for more than a century (Table 11-1).

11.1.2.5 Puluj in Vienna and Prague

Jožef Stefan's Physics Institute in Vienna investigated the properties of gases, first diffusion and then thermal conductivity in the 1870s. Thin films were studied mostly by Puluj, who borrowed a large Ruhmkorff apparatus from the court councillor Stefan to carry out a series of experiments with Geissler's tubes. He observed:

"... changes in the dark space of the tubes when using electrodes from various metals: platinum, copper, silver, and zinc. In an induced flow of about 6 cm long sparkle, the glass surface is covered with a metal mirror in half an hour. The metal coating is the thickest near the electrode and perpendicular to the illuminated pulsating discharge.

The electrode is covered with a dust of a copper oxide, like golden dust ... Near the negative pole of the convex magnet, the light of the pulsating discharge in the tube is coated with the metal surrounding of the electrode together with a small part of the glass tube. If we use the electrode of platinum, we get a nice platinum mirror on the glass plate.

Aluminium is the only known metal ever, where we do not notice the sputtering of mirrors on the glass, because it is difficult to remove aluminium. The weak coating obtained using aluminium is only observed in phosphorescence ... Aluminium is less sputtered on glass due to its chemical structure or adhesion."

Puluj has not yet linked the properties of aluminium with its place in the new periodic system of elements. His problems with the sputtering of aluminium mirrored late discovery of pure aluminium by Oersted in 1824 and by F. Wöhler which made aluminium still very expensive in Puluj's times. Unlike Hittorf, he has already separated the dispersion from the sputtering:[1436]

"With the horseshoe magnet we divert the dispersion to a smaller target. Against the platinum cathode, a mirror glass can be placed. A slight debris resulting from the sputtering of an aluminium electrode was attributed to impurities. Aluminium particles are also ripped from the cathode, but due to the difference in chemical composition or adhesion, they are not attached to the glass. There is no doubt that the cathode particles are tearing due to electric current and not due to evaporation and traveling at relatively high speeds. In doing so, they push the gas away from the cathode and diffuse into dilute gas. Since they move in one direction, their number must be three times greater than in the dark space, where they move with the same kinetic energy in all directions. The cathode space is relatively dark because there are fewer particles in it, and not because of the smaller number of particles in it, as Crookes claimed. Nor does Crookes' presumption hold that the dark space is equal to the average free path of particles in the gas, since this is much smaller in terms of Stefan'sresults. In the case of collisions, the particles of the electrode strongly shake the envelopes of the gas molecules, but do not heat them, while increasing their kinetic energy. Pulsed discharge is then a mixture of gas molecules and scattered parts of the cathode. At lower pressures, the dark room is longer and covers the whole tube at a pressure of 0.03 mm Hg but cannot reach 800 000 m/s, which Goldstein calculated m by his wrong assumptions. The fifty times lower pressure described by Crookes does not allow discharge at all. Pumping at high vacuum should be connected to the drying of the pump, since the main source of impurities are the

[1435] Hof- und Staats- Schematismus der röm. kaiserl. Wien: Joseph Gerold, 1908, 313.

[1436] Puluj, 1889, 241–246; Crookes, 1905, 115.

adsorbed gases which the cathode eliminates after heating."

Plücker's ideas were particularly well received at the Technical College of Prague. In 1880, Gintl, a professor of chemistry, rejected Crookes' idea of cathode rays as the fourth aggregate state of matter. He believed that the rays always extract metal particles from the surface of the cathode. The particles are then moved in a straight line until the gas in the emptied tube changes the direction of their movement or absorbs them. According to Gintl, "cathode rays" are supposed to be a stream of metal particles that have been removed from the cathode.

Wilhelm Friedrich Gintl was born in Prague. Between 1867 and 1870 he was a private assistant to Lippich at the German University of Prague, and then he was a regular m/s professor of chemistry at the Technical College of Prague after 1870. He criticized Crookes' idea of the fourth aggregate state of the substance[1437] like many other who published in German language.

The later Gintl's colleague in Prague, Puluj, linked Gintl's hypothesis with the one-fluid physics theory of the professor of physics at the Swedish Academy Edlung: "A powerful stream of ether outbreaks the particles from the negative pole in the exhausted cathode ray tube. The extracted particles fly linearly towards the walls of the vessel. They cause an apparent glowing of matter and accumulate as a metal mirror on the wall of the vessel. In the collisions of these cathode particles along the walls of the vessel, their living force (vis viva, equivalent of modern kinetic energy) changes into heat. However, this heat is not large enough for phosphorescence. The ether which transport the particles of cathode therefore causes the phosphorescence on the wall of the vessel. The collisions of the negative electrical particles from the electrode along the glass wall and the collisions of the substance molecules equate the pressure of the ether between the particles of the vessel and the molecules. The collisions on the ether envelope make the center of the new waves of the ether from each point of the hit glass wall of the vessel, which finally show up as the phosphorescence."[1438]

Puluj's theory was based on material atoms with an envelope from the ether. In 1857, such a model of the atom, called "Dynamide", was introduced by Redtenbacher and in the Habsburg monarchy Redtenbacher successfully competed with Clausius's kinetic theory, first published in the same year.

After Puluj, in 1883 Plücker's student Hittorf supported the assumption that metal particles originate from heated cathode and then they sit on the walls of a glass tube. In 1897-1898, the Swedish professor Gustav Grandquist proved that temperature change of cathodes on a wide interval do not affect the intensity of sputtering of metals in the emptied tube. With this Hittorf and Puluj's hypothesis was rejected.[1439]

11.1.2.6 Optical Properties of Thin Films in Strasbourg

Interference colors of thin films were one of the pillars of Newton's optics in the 17th century. Jamin and Fizeau's experimental methods and Drude's theory enabled the use of accurate methods for measuring thickness in the 19th century. At the end of the 19th century, the discharged cathode ray tubes and high voltage rectifiers became accessible to the upper secondary level schools. Nevertheless, the properties of thin films made outside ~~of~~ the vacuum were initially studied.

The thinness of thin gold sheets has already been studied by Young. The research was continued by the British astronomer de la Rue in collaboration with Faraday, who studied the transparency of thin sheets of all kinds of metals obtained by chemical and electrochemical methods in 1857. His discharged Leyden jar sputtered a golden conductor on the glass formed as a golden leaf. In Berlin, Quincke studied the thin layer density in air and in vacuum. Stefan has published important research on the optical properties of the interference rings of thin mica leaves.[1440]

In 1884, Kundt conducted the first studies of magnetic thin films of iron, cobalt, and nickel in which he measured the rotation of the polarization plane. In November 1885, he used a device resembling the American Wright's tool for

observing the high-quality interference rings in layers of various metals scattered from the cathode in September 1877. A ten inches long vertical glass cylinder was closed on both sides with smooth glass plates. From the bottom side, an aluminium electrode was deposited, and from the top Kundt inserted a metal cathode, intended for sputtering, which was attached to the tube by rubber, so that it could be changed during the measurements. It triggered a large induction apparatus with three to six Bunsen elements. Kundt used various metals, but his experiments were most fortunate with platinum. In the case of a cathode, 2 cm long, with a diameter of 0.2-0.5 mm, a horizontal plate was placed at the distance of 2 to 12 mm. He carefully removed oxygen and water vapor from the vessel. Even with the microscope, it was not possible to find the inhomogeneity of the cone-shaped mirror thus obtained with an average thickness of 10 nm and a maximum thickness just below the cathode. Kundt's discovery is today widely used in magnetic sensors and magnetic memories. This phenomenon was first observed by Faraday in 1845 and is still called by him today. In 1876, John Kerr reported about the polarization rotation of light, reflected from the magnetized surface.

Kundt experimented in vacuum in Strasbourg together with Puluj. In 1888 he replaced Helmholtz as a professor of physics at the Berlin Physics Institute. Kundt was surprised by the discovery of a double refraction (birefringence) of light reflectedat boundary between the metal and the glass surface of the mirror. The thin layer was described as a crystalline elastic membrane that is unevenly tensioned due to the charge of the dispersed particles and therefore causes a double refraction. In 1888 he measured the refractive index of the heat-treated platinum mirror.[1441]
In 1887, the director of the Berlin Higher School, Nahrwold, investigated the loading of thin films by vapour deposition from a melting pot. His measurements were supplemented by Alfred Berliner and Warburg in Freiburg. In the autumn semester 1886/87 and in March 1888, in Helmholtz’s Institute of Physics Nahrwold examined the charging of glowing cathodes made of the platinum, gold, copper, iron, nickel and antimony in the emptied tube. As the source of the current, Nahrwold used Daniel's element, and he emptied his vessel with the Töpler-Hagen pump. He continued the studies of J. Elster and H. Geitel (1887), Berliner (1888) and the secret counsellor W. Siemens, who darkened the glass of the cathode ray tube during 42 hours of glowing in a vacuum of steam of water. In his laboratory, Siemens supplied Nahrwold with 3 cm long hardened Platinum conductors, which did not sputter on glass even after 200 hours. Nahrwold proved that the cathode from platinum is much less dispersed in hydrogen than in the air.[1442] None of those German researchers mentioned Edison's Patent of evaporation (1884) and, of course, also not later Edison's Patent of sputtering the plates. In 1907 Soddy continued Nahrwold's research on sublimation in vacuum. Soddy proposed the calcium deposition on the substrate by reducing the remaining pressure in the emptied receiver.[1443] Soddy was Rutherford's student in Montreal, and he collaborated with Ramsay in England since 1902. In 1921, Soddy received the Nobel Prize in chemistry for his research of isotopes.

> The German physicist **August Adolf Eduard Eberhard Kundt** was born in Schwerin, 100 km east of Hamburg. In 1886, as a professor of physics in Strasbourg, he published the first discussion, which was entirely dedicated to the vacuum thin films. He worked closely with his student Röntgen, then professors in Würzburg. In Kundt's laboratory, Röntgen met with "cathode rays," which brought him world fame ten years later

11.1.2.7 Condensation and Evaporation in Berlin

Jamin in Paris and Magnus in Berlin investigated the condensation of steam and gases on solid surfaces and showed the importance of adsorbed layers and the connection with catalyst-like chemical processes on the surface. In 1873, Jožef Stefan proved that the rate of evaporation depends on the shape and magnitude of the surface of the liquid, and in some cases even on the shape of the surface. The evaporation takes place differently in the middle than on the edge of the surface. In 1886 Stefan calculated the pressure inside the liquid to prove the connection between the theory of capillary and the theory of evaporation. Sirk continued Stefan’s research of the connection

Table 11-1: Results of Wächter's cathode ray research

Property	Sputtered particles from cathode	Sputtered particles from anode
Pressure of gas at which they still are dispersed:	0.007 to 83 mbar	13 to 6000 mbar
Number of dispersed particles is to gas density:	inversely proportional	proportional
the dispersion range		is much longer
the surface which emits them	10,000 times larger	
sputtering is carried out by:	the whole cathode	by points closest to the electrode
form of the electrode is:	less important	important
removal from the non-oxidized surface	yes	/
the direction of sputtering	towards the electrode	perpendicular to the surface
direction of the motion	Random	linear with shadows behind obstacles
magnet curved them like:	paramagnetic substance	diamagnetic substance
particles are eliminated bright	No	yes and no
shape of particles	immeasurable small	measurable
Type of ejection	mechanical	evaporation
heating	helps in sputtering	Unknown
There are carriers of current from electrode	Yes	No
voltage necessary for sputtering		Larger

between surface tension and enthalpy of vaporization in Ljubljana in 1928.

In 1882, as a Helmholtz assistant in Berlin, Hertz investigated the rate of loading of substances in the distillation of metallic mercury in vacuum in two published papers. The evaporation rate is proportional to the difference between the mercury equilibrium pressure at a given temperature and hydrostatic pressure on the surface of the evaporating substance.

Due to the higher conductivity, mercury was more readily prepared for measuring than water. By simultaneous heating and pumping with a mercury pump, a vacuum of less than a millimeter mm Hg was obtained. Herz measured mercury evaporation at nine different pressures for the temperatures between 100 ° C and 200 ° C. Only measurements above 80 ° C were used, where the pressure significantly exceeded the measurement error of 0.02 mm Hg. Hertz found that at 100 ° C condensation was 0.9 mbar per minute.

In addition to Hertz, similar measurements were also published by Helmholtz's doctoral students Ernst Bessel Hagen (Carl G. * 1851 Königsberg; † 1923 Solln by München), Lucien Ira Blake (J. Black, 1854 Massachusetts-1916) and Ronker from the Physical Institute in Berlin in 1883. Measurements of properties of mercury were so interesting because of the Helmholtz theory of friction in fluids and pumps, where it was not possible to avoid traces of mercury in the emptied tubes.[1444] The precise measurement of the ratio between the specific heat at constant pressure and the volume of a single-atom mercury was particularly important for Boltzmann's equipartition theorem, which Helmholtz supported. Most of the mercury used was, naturally, flowed from the Carniolan Idrija.

Hertz derived from the results of his experiments the fundamental Hertz-Knudsen equation for the rate of evaporation. In 1909 the Dane Knudsen proved the validity of the cosine law for the evaporation of sulfur, zinc, silver, and SbS_3.[1445] On 24 June 1915, he demonstrated that Hertz measured lower velocities than predicted due to impurities on the surface of mercury.

[1444] Hittorf, 1883, 721; Jungnickel, McCormmach, 1986, 9; Hertz, 1895, 222.
[1445] Lafferty, 1998, 222.

In 1913 Langmuir found that the Hertz-Knudsen equation refers to evaporation from free surfaces. At first, as Coolidge's assistant, Langmuir studied the bonds between the atoms in the thin layer of gas on metal conductors that already attracted the research of Davy in 1822 and of Graham in 1866, since this gas deteriorated the vacuum after heating the cathode.[1446] Later, Langmuir investigated monomolecular thin films on water and on glass and continued the work of Rayleigh. For his theory of adsorption due to unsaturated valence bonding of atoms on the surface of the layer, Langmuir received the Nobel Prize in Chemistry in 1932.

In 1886 in Berlin, Goldstein discovered canal rays, which later proved to be a stream of positive ions. A decade later he let them through a hole in the cathode onto a gilded glass screen in a discharged tube. The golden coating has "disappeared" due to the burning bombardment of the canal rays.[1447] This was the first published description of the sputtering of metals with ion beam: he certainly chose golden coating because of Goldstein's surname.

11.2 Theories of Blistering of Metals

11.2.1 Stark's Theory of the Blistering of Metals

The Germans Berliner (1888), and Stark with Georg Wendt (1912) found the gas adsorption at the discharge causing the macroscopic phenomena of erosion. Wendt just got his PhD in Tubingen and left to research in Aachen as Stark's assistant for seven years. Their assumption was confirmed much later by experiments on gas bubbles that were observed during work on nuclear fuel. Today, the phenomenon is called "blistering."[1448]

Stark investigated the blistering of metals by the bombarding of positive ions at atomic level. The chemical reactions between the ionic missile and the atom on the surface were correctly estimated as less influential,[1449] differently from the opinion of Stark's compatriot Ernst Arnold Kohlschütter (1883-1969) at Mount-Wilson-Observatory of USA in 1912. Stark was one of the leading researchers of his time. He knew the success of Thomson's work in 1897, where the electrons were considered as particles in classical mechanics. That is why Stark himself described the process of atomizing metals with the law on the conservation of energy, which applied to elastic particles collisions in 1908 and 1909. He was roughly aware of the cross-section of the reaction, as it is now used in particle collisions in accelerators. In this way, Stark could correctly explain the energy dependence of the coefficient of sputtering yield (Y) in the bombarding of a metallic target with protons. Y tells us how many target atoms an average ion breaks out.

Y increases with energy at low ion velocities when a fraction of the energy of the ions is transferred to atoms near the surface of the target. At higher energies, ions penetrate deeper into the target, where most of their energy is collected. Therefore, at higher energies, Y does not grow any more with energy and we observe the saturation. However, the model was supported by experiments using accelerators only in the late 1950s, mostly after Stark passed away. Stark did not exaggerate the confirmation of his ideas, for in the meantime, unfortunately, he leaped into Nazi policies.

In his second model Stark assumed that microscopically small areas were heated to a melting point and evaporated under the influence of ion bombardment. Stark had a collision theory in the bombardment for a different view of the same process and, like Hittorf before him, Stark did not distinguish between sputtering and evaporation. Both Stark approaches treated microscopic quantities. However, the difference between them is like that seen in other areas of physics. The phenomena can be described phenomenologically by macroscopic thermodynamic quantities or by the motion of invisible particles. Similarly, the difference between the description of a group of phenomena and the treatment of individual events was linked by Bohr's special principle of correspondence.

11.2.2 Modern Theory

The experiments have shown that we can explain the blistering and sputtering due to bombardment only with Stark's local evaporation model. The difficulties in the first half of the 20th century mainly acquired from the poor knowledge of the motion of atomic particles with energies below

[1446] Hittorf, 1883, 735, 741.

[1449] Stark in 1908, 1909; Šubic, 1862, 107.

1000 eV in solids. Even today's progress in this area is not great, although we could damage the materials with high-energy missiles. Half a century later, Stark's mathematical formalism, was followed by F. Keywell (1952) and D. E. Harrison (1956, 1957, 1960) in modern networks with probability concepts and a cross-section of the reaction that was only in its infancy in Stark’s work.[1450]

The father of **Johannes Stark** was a landowner at Schickenhof in Bavaria. He attended gymnasium in Bayreuth and Regensburg. After 1894 he studied in Munich, where Boltzmann lectured on theoretical physics until that same year 1894, and Röntgen taught experimental physics in Munich after 1899. In Munich, Stark attended lectures in physics, mathematics, chemistry and crystallography and graduated in 1897 with a doctoral dissertation on persistent Newton coils in certain types of cloudy substances, certainly in connection with older Tait’s experiments with circuits of smoke. Stark was von Lommel's assistant at the Physics Institute of the University of Munich from 1897 to 1900. Röntgen refused to appoint Stark as his first assistant. So, in 1900, Stark left for an unpaid lecturer in Göttingen, where he researched cathode rays in 1903. In 1906 he became an associate professor at the Hannover Technical College, and in 1909 he was a professor at the Technical College in Aachen. In 1917, he accepted a similar position at the University of Greifswald, and in 1920 he went to the Physics Institute of the University of Würzburg, where he remained until 1922. He measured electrical currents in gases with a spectroscopic analysis to obtain the relationship between structure and spectrum, and chemical valence. In 1919, he received the Nobel Prize for discovering the Doppler effect in the canal rays and spectral line splitting in electric fields. He earned his prize in a private laboratory at Eppenstatt near Traunstein in Upper Bavaria. In the year 1933 Stark became president of the Physical and Technical Institute instead of von Pachen and retained his place until retirement in 1939. At the same time, he was president of the German Research Association. Stark has published over 300 scientific papers. In 1933 he challenged the discovery of Röntgen in favor of Hertz's student Lenard in a kind of revenge for Röntgen animosity thirty-three years earlier. The Jew Einstein ridiculed the theorizing of experimental physicists Stark, which stimulated Stark and Lenard’s Anti-Semitic ideas of German physics. As an activist of the National Socialist Party, Stark was convicted in 1947,[1451] just like his competitive discoverer of Doppler effect of canal rays, the Italian Fascist Antonino Lo Surdo (1880 Syracuse-1949 Rome) from the Physics institute in Rome. Coincidence or the canal anode rays of Jewish wine-merchant’s son Goldstein and Salzburg mason’s son Doppler effect politics?

Blistering and sputtering are the results of the expansion of current cascades that occur in collisions of incident ions with solid atoms and in collisions between these atoms. The cascade spreads in all directions. At the point where it reaches the surface of the substance, one or more atoms can leave the surface. In this case, the kinetic energy of the atom must be greater than its binding energy on the surface, which measures about 25 eV. The emergence and expansion of the current cascade can be simulated on computers today.

In 1969, Peter Sigmund published a phenomenological description of the dispersion that agrees well with experimental data. The spatial and energetic properties of the current cascade have been described with the distribution function calculated from the Boltzmann’s transport equation. Such a model enables us to describe the general dependence of the sputtering yield Y. We calculate it as a variable, depending on the type of bombarding ions, their energy and the angle of incidence, without much insights into the microscopic details of the expansion of the collision cascade into the substance. The details of the cascades become important especially for the measuring of absolute size of the coefficient of dispersion and quantities, such as the angular and energy spectra of the scattered particles.

11.2.3 Conclusion

Sputtering is a non-thermal mode of evaporation of a substance that was first observed after the metal cathode was bombarded by ions of high energies a century and a half ago. It was among the first discoveries of cathode ray researchers. Initially,

[1450] Sigmund, 1981, 13.

[1451] Harig (Garig), 1936, 301–308; Asimov, 1978, 567.

they were not pleased at the labs, as sputtering reduced the usefulness of cathode ray tube. When, however, the cathode ray tube moved from laboratories to industry in the 20th century, thin films proved to be one of the most useful discoveries. The harmful side-effect began to bring profit, as history happens to make us all happy. Relations turned upside down: arc discharge is only an interesting light phenomenon today, and research of once-annoying phenomenon of thin layer non-thermic Grove's (1852) and Robida's sputtering as well as much faster thermic evaporation of Robida's student Stefan (1871, 1873) had evolved into one of the most profitable modern technologies even if bothered by Stark's (1912) blistering.[1452] The metal of the electrodes gradually vaporizes during everyday use of a neon bulb causing blackening at end of a low-pressure mercury-vapor gas-discharge fluorescent lamps known as sputtering and can be observed as the glass capsule darkens by deposition of vaporized metal. The sputtered emission mix forms the dark marks at the lamp ends seen in old lamps. The vaporized material adheres to the glass surrounding the electrodes, causing its darkening and turning black.

[1452] Blistering as Slovenian mehurčenje, sputtering as non-thermic slower process (Slovenian: naprševanje tarče po razprševanju), quicker vaporization and evaporation by great heating (Slovenian: naparevanje po intenzivnem segrevanju).

12 New Materials with their Thin Films: Vacuum Metallury

12.1 Vacuum Metallurgy

12.1.1 Introduction

Robert Hare was born in Philadelphia, where he also died. He was the son of an English immigrant who founded a large brewery in Philadelphia very early, soon to be actively managed by his son Robert. Thus, Robert Hare's life path was much like the exploration of his younger English contemporary, the brewer Joule. Hare attended a course on Chemistry and Physics in Philadelphia. Even before the age of twenty, he became a member of the Chemical Society, where he published a significant discovery of the blower for hydrogen and oxygen, which he called "hydrostatic" in 1801. Elder Silliman collaborated with Hare in experimenting and called the device a "composite blower". He had it for the first and perhaps the biggest Hare's contribution to science. In June 1803, Hare reported to the American Philosophical Society about the melting of strontium and evaporation of platinum in a newly designed device. With this device the first was obtained in great quantities of molten magnesium, iridium and platinum. Hare's discoveries were used in Drummond's and calcium lamps. Hare invented valves and screws for perfect air sealing of the device. He also made strong batteries even before the Europeans. In 1816 he invented a calorimotor, a battery that produced a lot of heat. In 1820, the device was improved, and it was used three years later for evaporation of molten charcoal. With these batteries, under the leadership of Hare, the first underwater explosion with the Voltaic cell was carried out in 1831. He also excelled as a chemist and invented the procedure for the removal of narcotic properties of opium tincture and for the detection of low concentrations of opium in the solution. In 1818 he became professor of chemistry and natural science of College William and Mary, and in the same year he became a professor of chemistry at the medical department of the University of Pennsylvania and remained there until 1847. He then left his set of devices to the Smithsonian Institution. Later, like Crookes, he devoted himself to spiritism and lectured about it. In 1806 he received the honorary title of the University of Yale, and in 1816 of Harvard. In 1839 he received the first Rumford Prize for his blower and for improvements to galvanic cells. He was a member of the American Academy of Sciences and Arts, since 1803 he was a member of the American Philosophical Society and an honorary member of the Smithsonian Institution. Only in Silliman's American Journal of Science he has published almost 200 papers. He also published moral papers, often under the pseudonym Eldred Grayson. He wrote many books in which he dealt with both explosive nitrogen and spiritism.

Vacuum metallurgy is the manufacture, design, study and use of metals and alloys under reduced pressure, extending to the ultrahigh vacuum. The use of a vacuum has the following advantages:[1453]

1) When the pressure of the gases generated during the reaction is lowered, this increases the gradient of the concentration. In this way, the degree of reaction can be increased in many useful cases.

2) By diluting the gases, we move the balance against the reactions we want to observe

3) The high vacuum obstructs the reactions between the metal vapors and the remaining gases

4) The residual gas pressure falls so low that the average free the path of the gas molecules becomes large compared to the size of the container and allows greater evaporation

5) The elimination of nitrogen and oxygen increases the stability of many substances.

Bellow, we will describe the investigation of melting, degassing, metallurgy of metal evaporation (reduction) in vacuum and some applications of thinning and sputtering of thin films.

[1453] Winkler, Bakish, 1971, 145; Bunshah, 1994, 939–940.

12.1.2 Arc Melting of Metals in Vacuum

During the centuries of development, five methods of melting of metals in vacuum have been established:

1) In resistive melting furnaces Rohn used his vacuum as early as 1918, although the process did not apply in the industry

2) Vacuum melting in an arc with a meltable or permanent electrode

3) Vacuum induction melting in vacuum or in a neutral atmosphere

4) Melting with an electron beam

5) Growth and cultivation of crystals of reactive metals and alloys in a vacuum.

From these five methods, let's take a closer look at three, since the first one is not really established, and the latter is somewhat not in the context of metal production.

12.1.3 Melting of Metals in a Vacuum

The Vacuum metallurgy was used for the first time in melting with an arc. In 1839 Hare supplied oxygen and hydrogen to the arc through the cathode ray tubes. He melted platinum and produced calcium carbide, phosphorus, graphite and calcium. His invention was used to illuminate the stage in theaters, whose hits in the center of attention are often placed under "limelight" even today.[1454]

In 1856, William Siemens compiled a "regenerative" melting furnace to replace Bessemer's designs. In 1878 he compiled an electric metal melting furnace and patented it in Britain next year.[1455]

The Slovenian ancestors, the descendants of renowned ironworks, read about Siemens's "electric swimmers": "On the left we see the vessel used for melting. To its bottom, a positive current is kept with a stick of platinum or charcoal. The vessel is squeezed with pieces of metal, which we intend to dissolve. From the top extends into the pot the vertical carbon rod, which is with wire A in relation to the negative pole. From the beginning, this stick touches the metal fragments, but when the rod begins to circulate, the rod with an automatic device is raised a few millimeters to create a flamed arc that dissolves metal fragments. If the metal is lowered by melting, the carbon rod is equally lowered by the self-regulation so that the dissolving flame arc does not stop (Figure 12-1).

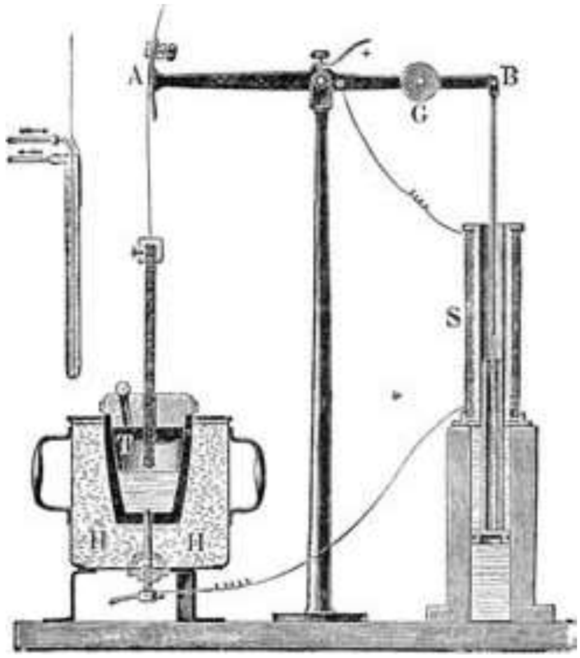

Figure 12-1: Electric smelting of Siemens[1456]

Siemens was, of course, among the inventors of the operation of a new melting furnace. He tried to sell it well, therefore he displayed its facilities in public. He placed his pound of shavings in a melting pot and liquefied it with a current of 70 A in 13 minutes so that he could pour it in. In the hot melting pot, the same amount of substance could be melted after 8 minutes.

William Siemens' arc furnace was used for melting and fusing smaller amounts of metal at higher temperatures. Even in the production of larger quantities of iron, it was more useful than a furnace which he developed simultaneously with his younger brother Friedrich Siemens. In 1864, the father and son, the Frenchmen Émile Martin (1794 Soissons -1871 Fourchambault) and Pierre-Émile Martin (1824 Bourges-1915 Fourchambault), commissioned its use in industry as Siemens-Martin's furnace.

[1454] Bowers, 1998, 57–58.
[1455] Bunshah, 1994, 938.
[1456] Šubic, 1897, 201.

In 1906, the Frenchmen Moissan received the Nobel Prize for chemical research in a melting furnace heated by the arc discharge formed in 1892. By lowering the electric current between graphite, the electrodes reached temperatures up to 3500 ° C. In 1893 he first acquired artificial diamonds and hydrated tantalum, which he mistakenly had for pure metal. Three years later, he investigated uranium and prepared some compounds for H. Becquerel's pioneering work on radioactivity.[1457]

German **Werner von Bolton** was the son of the manager of the Siemens copper mine in Tbilisi (Tiflis). In his younger years he came to Berlin, where he was supported by Werner Siemens. He studied in Charlottenburg-Berlin and Leipzig, where he received his PhD at Ostwald's class in 1895. Already during his studies, he published a discussion about copper and about the bulb. Between 1896 and 1902 he developed tantalum bulbs in the Siemens & Halske Bohneshof laboratory in Berlin-Moabit and assisted William's nephew, Wilhelm von Siemens. At the time it was founded in 1902, he became head of the Siemens Laboratory of Photoelectric Laboratory and Halske AG in Berlin, where he also died in 1912.

Von Bolton was the first to eliminate 99.5% pure tantalum, of the ore that had been known in the compounds for centuries[1458]. He composed a melting furnace on an arc with water-cooled nickel electrodes. He discharged the vessel and prevented the oxygen supply. With von Bolton's device, molten metal was later deposited on glass of cathode ray tubes.[1459]

The experiments showed that pure metals have many different properties than ordinary metals in alloys. Von Bolton was primarily looking for the pure metals as charcoal substitutes in Edison's bulb: "The technical goal of my research was to find a metal suitable for an incandescent lamp in an electric bulb, that is a metal with a melting point above 2000 ° C, which would not too sputtered by electricity and could be easily formed into a wire ..." Among niobium, vanadium and others Bolton chose the tantalum. His pure tantalum was obtained by electrolytic reduction from tetroxide, and by melting of the tobacco dust in the flame of the electric arc. By reduction, he heated the tantalum oxide in a emptied receiver and thus extracted gas oxygen. From a brown oxide a gray metal like a platinum could be minted and formed. In 1905 and 1906 he liquified the tantalum by arc of a melting electrode with a layer of charcoal, whose elasticity was reduced by the addition of wax. He melted in a vacuum with traces of argon and got about a ton of tantalum. In determining the density and other properties of the tantalum he was assisted by a young doctor Pirani, a later pioneer of vacuum technique.[1460] Due to the small specific electrical resistance of the tantalum, von Bolton had some problems with the use of a bulb with a 0.05 mm thick and 650 mm long wire. He measured an average lifetime of 1000 to 1500 hours at 1.3 W / cd consumption of several hundred tantalum bulbs; at that time, a very good achievement.

In 1907, von Bolton carried out similar experiments with niobium, which he also directly reduced in alternating-current electrolysis in vacuum or by arc glowing in a vacuum. However, the niobium lamps lit only 8 to 14 hours, so they did not seem particularly promising. The pure niobium was much more difficult to obtain than the tantalum, as it had to be vacuumed up to 200 times.

As early as January 1905, Siemens & Halske began to sell von Bolton's tantalum bulbs. In 1914 they sold 50 million pieces; later they were expelled from the market by GE's tungsten light bulbs designed after Coolidge's patent from 1909.

The use of the simple von Bolton process has grown considerably half of a century later without the physical background being fully explained. The methods were no longer used so much to produce tantalum, but remained indispensable for production of zirconium and hafnium. High vacuum sintering is still suitable today for production of pure grain tantalum, but not for niobium and its alloys. In the production of ductile tungsten tantalum, the "Coolidge process" of sintering with the direct passage of the electric current prevailed (Figure 12-2).[1461]

At the time of von Bolton's experiments, the German engineer Otto Archibald Simpson designed

[1457] Šubic, 1897, 203; Hurd, 1964, 367.

and built a melting furnace with an arc to liquify tantalum for Siemens & Halske of Charlottenburg between 1903 and 1913.[1462] The tantalum was used in lamps and for surgical devices. In 1909, Ludwig Weiss of inorganic lab of Munich Polytechnic (anorganische Laboratorium der technische Hochschule München) and Anton Stimmelmayer (Stimmelmayr, 1884 Dingolfing in Lower Bavaria-1963) for his published Ph.D. defended in the royal Munich Polytechnic (Technische Hochschule zu Munchen) melted tungsten in the atmosphere of hydrogen, ammonia, nitrogen and in a vacuum. Four years later in Strasbourg chemistry lab (Chemisches Institut der Universität Straßburg) Edgar Wedekind (1870 Altona by Hamburg-1938 Erfurt) used fusible electrodes of the arc for the melting of volatile zirconium borides, other borides and similar compounds in a vacuum.

DAS NIOB, SEINE DARSTELLUNG UND SEINE EIGENSCHAFTEN.

Von Dr. *Werner von Bolton.*

I. Einleitung.

Im Jahre 1801 entdeckte der amerikanische Chemiker Hatchett in einem Mineral Nordamerikas, dem Columbit von Massachusetts, eine eigentümliche Säure, die er Columbinsäure nannte. Aber erst Heinrich Rose erkannte durch eifriges, unabhängiges Studium die wahre Natur dieser Säure, die er häufig mit Tantalsäure vergesellschaftet fand, und die er Niobsäure nannte. Im Verlaufe seiner diesbezüglichen klassischen Arbeiten glaubte er noch ein Element im Niob gefunden zu haben, das er Pelopium nannte, welches sich aber schliesslich auch als Niob erwies. Auch das Dianium Kobells und das Ilmenium Hermanns, sowie das Neptunium 1) desselben Forschers erwiesen sich als Niob, bezw. als Gemische von Niob mit Titan.

Das Niob kommt in der Natur meistens vergesellschaftet mit Tantal vor, und zwar überwiegt gewöhnlich der Niobgehalt in solchen Mineralien denjenigen von Tantal ganz wesentlich, namentlich in den Columbiten, es gibt aber auch eine grosse Reihe von Mineralien, die niobhaltig und dabei tantalfrei sind, wie z. B. Euxenit, Polykras, Pyrochlor u. s. w. Natürlich fehlte es nicht an Bemühungen, aus der Niobsäure das Niobmetall zu isolieren, und Blomstrand 2) glaubte es auch erreicht zu haben, indem er Niobchlorid mit Wasserstoff im glühenden Rohr reduzierte, wobei er einen metallgrauen, spiegelnden Ueberzug erhielt. Roscoe 3) verfuhr in gleicher Weise mit Pentachloriddampf und erhitzte den entstandenen Niederschlag nochmals heftig in Wasserstoff, wodurch er ein Produkt erhielt, das angeblich nur 0,27 % *H*, etwas Chlorid und Oxyd enthielt. Wir werden aber im Verlauf dieser Arbeit sehen, dass es auf diese Weise unmöglich ist, Niobmetall zu erhalten. Ebensowenig gelingt seine Isolierung durch Reduktion des Oxyfluorids mit Natrium, wie es H. Rose und Hermann versucht hatten, die auf diesem Wege nur Nioboxydul erhielten 4), einen metallisch aussehenden, den elektrischen Strom gut leitenden Körper. Goldschmidt 5) wandte sein bekanntes aluminothermisches Reduktionsverfahren auch zur Reduktion der Niobsäure an, erhielt aber dabei eine Legierung von Niob mit Aluminium 6). Weiss und Aichel reduzierten verschiedene Metalloxyde mit Hilfe des sogen. Mischmetalls, einer Legierung der Ceritmetalle, und erhielten bei der Reduktion von Niobpentoxyd einen Regulus, den sie für reines Niob halten 7); die angegebenen physikalischen Eigenschaften des erhaltenen Materials stimmen aber nicht mit denen des reinen Metalles überein, wie weiter unten gezeigt wird, so dass auch das Weiss-Aichelsche Produkt kein reines Niob sein kann.

Eine Niobschmelze erhielt H. Moissan 8) durch Erhitzen eines Gemisches von Niobpentoxyd mit Zuckerkohle im elektrischen Ofen bei 600 Amp. und 50 Volt. Er erhielt auf diese Weise eine geschmolzene Masse mit metallischem Bruch, die sehr hart war, Glas und Quarz ritzte und oberhalb 1800° schmolz. Die analytische Untersuchung ergab aber einen chemisch gebundenen

Figure 12-2: The introductory page of von Bolton's discussion of niobium (1907).

In 1923 Roy W. Moore of Schenectady GE melted uranium at a pressure of 10 μm Hg in argon gas. He picked up a tungsten electrode covered with uranium. Twelve years after him, In November 23, 1935 in his electric arc welding apparatus designed for M.W. Kellogg co., Robert K. Hopkins used a cold crucible and a melting electrode to smelt the metal and to purify it with drops that went through the melt flow; this was the precursor to the modern electrical slag elimination process.

12.1.4 Vacuum Induction Melting of Metals

In 1890, Lake described the melting of metal in a circular tube. The metal was poured into the models by tilting the entire melting furnace. That same year in USA, Edward Allen Colby patented the foundations of modern vacuum induction melting in a melting furnace from a emptied receiver. The low-frequency induction coil was connected to a model connected over the opening. In 1904, William C. Arsem (P., * 1881 Massachusetts) at GE headquarters in Schenectady designed a vacuum resistive metal cleaning agent by evaporating impurities, promoting metallurgical gas reactions, and protecting reactive metals against pollution. He developed a vacuum water-cooled metal degassing vessel, a spiral graphite heater and a graphite screen. His devices are still used to analyze gases after melting in a vacuum. Three years later he developed various separation metallurgical operations at temperatures above 1500 ° C.[1463]

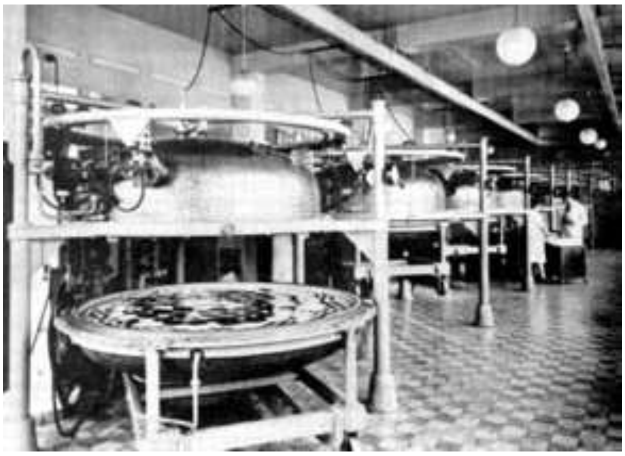

Figure 12-3: Production of thin films at the W.C. Heraeus in the years 1940-1944

In the next decade Rohn began to develop commercial vacuum melting in large melting furnaces. In 1917, he melted nickel alloys with Joule's heat and patented the process next year. In 1921, he used a low-frequency vacuum smelting furnace with a mass of 300 kg at Heraeus, which until then was known primarily for production of quartz lanterns. Three years later, he described the production of pure chromium by reducing oxide by hydrogen. In 1928, he used a 4-tonne 350 kW power source for casting 2-ton ingots. He produced thermocouple and alloys for resistant heating. In

[1462] Bolton, 1905, 48.

[1463] Bunshah, 1994, 938.

1929, Rohn developed a large melting device for melting metal at a pressure of 10 to 50 mm Hg. Adding iron oxide or chrome ore reduced the percentage of carbon in molten ferrochrome from 1% or 3% to 0.04%.[1464]
Between the two world wars, the Germans needed solid metals withstanding very high temperatures, of course, especially for turbines of aircraft engines for their new massacres (Figure 12-3). In 1932, Rohn began producing metal, especially useful for thin conductors. However, poor vacuum systems prolonged the pumping to 14 or 15 hours, and the use of the Rohn's process was hampered by low demand in the economy.

During the same Rohn's era, Trygve Dewey Yensen (1884-1950 Pittsburgh) tested at his workshop the smelting of magnetic materials in Westinghouse's lab of East Pittsburgh in the United States. However, industrial devices did not develop before the Second World War. The development was accelerated by the nuclear industry using titanium in the early 1950s, and later by using Ni-alloys for turbine blades.[1465] The British Telegraph Construction and Maintenance Co. began to produce electric and magnetic alloys in the 1930s.

Father **Wilhelm Julius Paul Rohn** was the rector of the College of Dresden, and the uncle was the director of the Chemists' Association in Meinheim. Between 1905 and 1911 Rohn studied in Leipzig and Strasbourg, where he was a student of Braun, an inventor of a cathode-ray tube. In 1912, Rohn investigated anomalous dispersion and fluorescence. He continued the work with Braun, and in 1922 and 1923 he received a German patent for the improvement of the vacuum tube. He had been experimenting in physics since 1913, and in 1923 he became the head of Heraeus.

12.1.5 Metal Melting with an Electron Beam in a Vacuum

The electrons in the material itself produce heat for melting and segregation. The melting by an electron beam causes local temperature rise by electron collisions, wfighich was already observed by Grove during the rapid oxidation of a positively charged metal plate on which the electrons were directed from the point of the platinum conductor in 1852. He also melted iron, "which was particularly instructive: the iron evaporated in the Voltaic arc, both in a nitrogen container and in a vacuum. The container was covered with a perceptible stain ... Thus, we indeed distil the iron, which melts by ordinary tools only at very high temperatures (Figure 12-4)."[1466]

In 1879, Crookes heated platinum to a white glow and melted it during a "cathode ray" bombardment. At the focus of the cathode, in the form of a convex mirror, he melted the platinum and iridium alloy. The melting of target in the vacuum tube after electron bombardment was an experimental inconvenience, from which the modern processes of melting of metals and bombardment of metal with electrons have been developed;[1467] the same happened to the initially harmful thin films at the wall of the cathode ray tubes.

DIE VERWANDTSCHAFT

NATURKRÄFTE

Dr. W. R. GROVE,

Braunschweig,

1871.

On 17. 9. 1907 in the United States, Marcello von Pirani patented the melting of tantalum and other metals in electron beam. The process contained most of the basic ideas of the modern industry and even the later Temescal electronic gun system from the 1950s. In May 1908 in Scientific American, Charles Algernon Parsons and Alan Archibald Campbell Swinton described their use of electrons to investigate the conversion of diamond into graphite. Early electron beam melts were also contributed by E. Tiede in 1913 in Germany, F. Trombe in 1934 in France, and Ralph Hultgreen and M. H. Pakkala in 1940 at Graduate School of Engineering, Harvard University, Cambridge, Massachusetts in the United States. Nevertheless, the process did not become useful, since there were no major needs in industry before 1954; then, riding on the new user's wind, the researchers of Berkeley's electronics accelerator were united in their new firm Temescal. In 1938 von Adrenne was the first to use a jet of electrons for a working tool. In the mid-1950s, electrons were used for welding, which the Frenchman Jacques-André Stohr of Commissariat à l'énergie Atomique and W. L. Weyman described in 1958 for the needs of the nuclear industry. In 1953, Karl-Heinz Steigerwald (1920 Koblenz-2001) began cutting with an electronic beam for AEG Research Institute in Mosbach, Baden, later for Zeiss and for his own firm. These discoveries gradually developed into various forms of heat treatment of metals in a vacuum. For the first time and for a long time, the only book dedicated entirely to melting electron beam was issued in 1965 in the Soviet Union, where melting systems like von Ardenne's electronic rifles were developed in Moscow.[1468]

12.1.6 Degassing of Metals in a Vacuum

The degassing process is used as the name of the process due to historical circumstances, although today we know that the steel contains most of the gas molecules in the form of compounds. Similarly, the game of outdated words is kept in the setting sun, the shining of the moon, positive electricity at points with a deficit of electrons and similar expressions, which have already become too much domesticated to allow any altering by new scientific discoveries.

12.1.7 The Theory of Absorption and Degassing of Metals

The professor of chemistry in Brussels, Louyet, studied the flow of hydrogen from the capillary through 1 mm of distant leaves from gold, silver and other substances already in 1848. Few months later poor Louyet died because of his extensive experimenting with the toxic fluorine even if he used his protective mask. Two decades later, the Parisian professor Sainte-Claire Deville from École Normale Supérieure and his former Ph.D. student Troost, measured the permeability of metals for gas. The cast iron furnace, which was used in Paris for heating military guardhouses, was wrapped in iron mantle and placed in a built cavity where they could warm their furnace up to a dark or bright red grill. They exhausted the air and explored the remaining hydrogen and CO_2. By 1000 l of air they got a residual of 0.23 to 1.07 l of hydrogen and 0.22 to 0.71 l of CO_2. In the second experiment, it turned out that hydrogen from a closed cast iron tube, heated in the furnace shortly, was completely expanded into a vacuum. Later, they measured the permeability of metals for gases: they tried to figure out if the gas flows through the pores of metal or was absorbed on one side of the metal sheet and eliminated on the other.

Mining engineer **Louis Paul Cailletet** worked as a young man in his father's blast furnace at Chatillon-sur-Seine. In the 1870s, he investigated the properties of real gases, and he liquified the oxygen for the first time in December 1877. Since he was just elected as a correspondent member of the academy at that time, he delayed publication of his discovery for a few weeks, so he was nearly overtaken by Pictet in Geneva in a case of simultaneous discoveries as problem was appealing and the tools for discovery were at hand. Priority was given to Cailletet’s letter in which he disclosed his discovery to his friend Sainte-Claire Deville in a timely manner. In 1878, Cailletet received the Davy Medal, in 1884 he was elected as a regular member of the Academy in Paris, and in 1889 he became a Legion of Honor Officer.

Cailletet's experiments supported the first assumption in 1868. He used a thin iron sheet with a cavity in the middle. Through the thin copper

[1468] Winkler, Bakish, 1971, 593–594, 613–614.

tube, he translated gas from the cavity. When the ferrous container was placed in H_2SO_4 or HCl, the boiling bubbles of pure hydrogen soon began to emerge from the copper tube. Cailletet explained that gas bubbles develop in course of acid action on iron. Then acid prevents their outflow but they pass through the iron inwards. From here it follows that iron is also transient for gas at normal temperatures; gas extraction is proportional to the surface of the pig iron. He believed that the gas flow was not affected by the special force, but the gas freely breaks through the pores of iron.

In 1866, Graham confirmed the older results of Sainte-Claire Deville and Troost that hydrogen diffused through the heated platinum cathode ray tube. By the palladium cathode ray tube, he separated hydrogen from a mixture of gases. Graham measured that palladium absorbs about 900 times the greater volume of hydrogen compared to its own. In experiments, Graham used only a simple vacuum pump and a tube filled with the mercury.[1469]

The Scotsman **Thomas Graham** studied in Glasgow. Between 1830 and 1837 he was professor of chemistry there. In 1831, he published a law called by his name. He stated that diffusion of gas is inversely proportional to the square root of the mass of its molecules. In 1837 he became a professor of chemistry at the University College in London. In 1854 he took over the former Newton's position as head of the state treasury as the last Master of the mint, but, unlike Newton, he continued to publish his scientific research without much alchemy involved.

Graham disliked the pores in the metal. Graham opposed Cailletet's assumptions and explained the experimental results by absorbed gases in metals. He argued that the transition of hydrogen through a thin iron sheet at lower temperatures from Cailletet's experiment can be done by the acid itself. In any case, hydrogen was absorbed in iron at a considerable level at these temperatures. At very high temperatures, soon above the red beam, hydrogen was eliminated. Similarly, according to Graham, happens in platinum and palladium, which absorb hydrogen the most among all metals. At normal temperature bellow 100 ° C in the vacuum, palladium does not let hydrogen through: "Therefore, I believe that the transfer of hydrogen through the metal always follows the gradient of concentration or absorption of gas. I am justifiably assuming that the speed of the passage is not proportional to the volume of the absorbed gas, otherwise palladium would be much more permeable at lower than at higher temperatures. At temperature of 267°C the palladium plates eliminated all their hydrogen which they contained at lower temperatures but remained permeable. The palladium permeability increases at higher temperatures when the quantity of hydrogen retained in the metal can no longer be observed. I believe that the hydrogen is still there, but a kind of rapid hardening happens to it in the metal."[1470]

The palladium gave away all its hydrogen at a temperature of 267 ° C but remains permeable for the same gas. This to some extent opposed to Graham's view, since it is difficult to believe that the metal at the temperature at which all hydrogen is already released does still absorb the same gas. According to Graham, the rubber, which at all temperatures eliminates all absorbed hydrogen, is still more permeable for hydrogen than CO_2. Graham's interpretation of the experiments did not support the free flow of gas through the pore of the metal. Graham's transfer of hydrogen and CO_2 through the metal should be like the diffusion of the liquid through the semi-permeable membrane, while at the same time there will be an attraction and reflection of the liquid.

Graham did not have gas absorption in a metal for normal mechanical motion, but for some special kind of chemical coupling. Hydrogen absorption changes the density, strength, electrical conductivity and other physical properties of palladium. The absorbed hydrogen does not behave like plain gas. That is why Graham treated hydrogen absorbed in palladium as a palladium alloy with another metal, which was initially well received between physicists and chemists. Today, such phenomena are called chemisorption and the permeabilities of organic membranes provide one of the clues into the secrets of life processes.

In 1820 the first quantitative measurements of oxygen solubility in silver at normal pressures were already published by French Gay-Lussac at

[1469] Bunshah, 1994, 936, 938; Grove, 1871, 132.

[1470] Rosenberger, 1890, 622–625.

temperatures up to 1125 ° C. A century later, Sieverts placed metal in a quartz cylinder (at higher temperatures he preferred porcelain) and connected it with a burette, like Hans Hugo Christian Bunte's (* 1848 Wunsiedel; † 1925 Karlsruhe) burette designed for gas analysis in 1887. With Töpler pump Sieverts first emptied the cylinder and then released the measured quantity of gas through the burette. Sieverts measured the temperature with a thermocouple and determined the pressure by the mercury level difference in the U-tube.

Adolf Ferdinand Sieverts was born in Jena, and after 1894 studied in Dresden, Leipzig and Göttingen, where he received his Ph.D. from Wallach in 1898. In 1910, Wallach got his Nobel Prize in chemistry for his research of terpenes. Between 1907 and 1919, Sieverts taught in Leipzig. In 1922, he became a professor of inorganic and analytical chemistry in Frankfurt, on Main, and since 1927 he was a professor and director of a chemical laboratory at the University of Jena.

ZEITSCHRIFT FÜR METALLKUNDE

Die Aufnahme von Gasen durch Metalle

Figure 12-5: The title plate of the Sieverts discussion (Sieverts, Die Aufnahme von Gasen durch Metall, Z.Metallk., 21 (1929) 37, 38)

In 1928 at the main assembly of the German Metallurgical Society in Dortmund, after numerous experiments Sieverts and his students announced that the mass of the dissolved gas molecules in the metal is proportional to the square root from the partial pressure of the gas at a constant temperature. Similar issues, closely related to the kinetic theory of gases, have been discussed since Graham's time. That's why some opposed Sieverts' results. Among them, the Berliner professor M. Pirani assured that, in his decade long experiments with palladium and iron, the solubility of the gas was never related to the rate of gas diffusion in the metal. Pirani was of course a respectable man; despite of this, Rohn and others supported Sieverts' correct theory (Fig. 12-5).[1471]

12.1.8 Degassing of (Liquid) Steel in a Vacuum

On 27 July 1865, Bessemer described the use of models in an empty space into which the liquid steel or iron was applied using atmospheric pressure in his patent for the "extraction of iron and steel without burning materials".

Henry Bessemer was a descendant of French emigrant of English descent Anthony who returned to England scarred by the Revolution at the end of the 18th century. Anthony Bessemer used to be a member of Parisian academy of sciences in 1784; his forced migration repeated the loss of French intellectual potential during the exodus of Huguenots a century earlier. In 1855 Henry Bessemer compiled his first converter. However, the publication of the invention did not bring success to him in 1856, as he needed iron ore without phosphorus, which was mined primarily in Sweden. After 1860, he enriched himself with the Sheffield Steelworks. The low price of steel, obtained through new processes, triggered the rapid production growth. Bessemer worked as an engineer in London, where he became afellow of the RS in 1879. A century earlier on 14 December 1687 the same Royal society elected the Carniolan Valvasor as a fellow. Like Bessemer, Valvasor reported to London about his invention of a special procedure for casting thin metal surfaces on August 29, 1686. Valvasor used it to make metallic statues while Henry Bessemer preferred iron.

[1471] Rosenberger, 1890, 626.

The American Robert H. Gordon patented modeling of ingots in a vacuum in 1883. In 1897 in Germany E. May patented an device for simultaneous casting of several models in an emptied receiverl (Figure 12-7). In 1885, Compressed Steel Comp. received a German patent for a different casting system that excluded the atmosphere and could be used for production of steel.

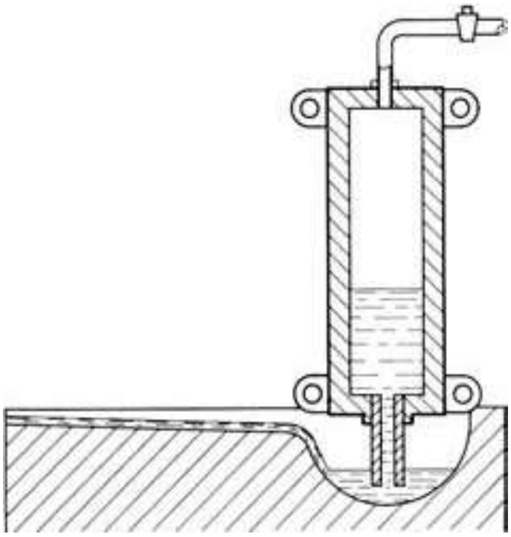

Figure 12-6: Bessmer's proposal for steel casting from 1865[1472]

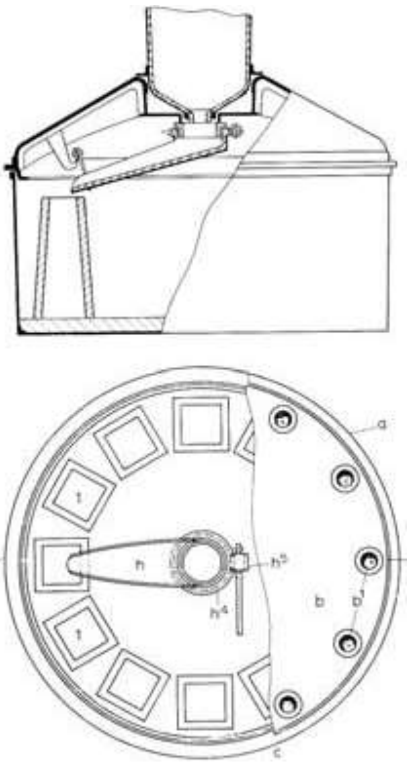

Figure 12-7: May's proposal for steel casting from 1897[1473]

[1473] Winkler, Bakish, 1971, 339.

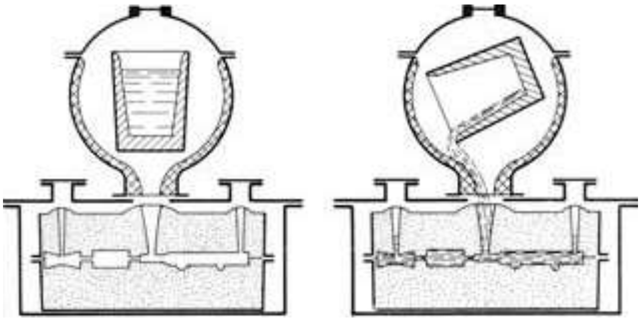

Figure 12-8: Simpson's proposal for steel casting issued in 1892.[1474]

At the end of the 19th century, the designers began to place melting units and models in an emptied receiver. In 1889, E. Taussig obtained a German patent for a single-phase electric furnace with a mold in an emptied receiver. He obtained additional English and German patents in 1893. In 1892, W. S. Simpson patented the frying pan instead of the melting furnace, which he placed together with the mold in his emptied receiver (Figure 12-8).

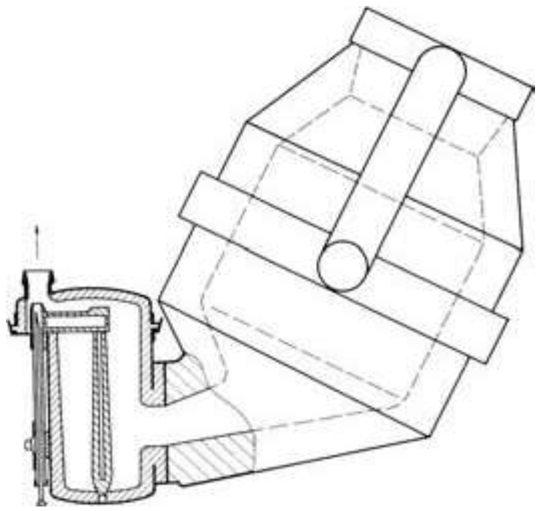

Figure 12-9: Tholander's proposal for steel casting from 1881.[1475]

The researchers repeatedly patented the degassing during the flow of melt into the frying pan. On 30. 5. 1874, the Swede Henrik Evald Tholander (Thålander, 1847 Stockholm-1910 Stockholm) obtained his Ph. D. in Uppsala and he met later famous mathematician Henri Poincarré on 22. 8. 1878. As an experienced Swedish mine and metallurgy expert, Tholander patented the production of Bessemer's steel ingots in Germany in

[1474] Winkler, Bakish, 1971, 341; Wilhelm Borchers, *Design & Construction of Electric Furnaces*, Watchmaker Publishing, 2005, 28-30.
[1475] Winkler, Bakish, 1971, 341.

1881. He proposed a coupling connection of the vessel in exhausted container with the converter mold through the vacuum seals. The steel in the melting pot would degas during the overflow. At the end of the process, the melting vessel and "Bessemer’s" would be separated, and steel was casted in the usual way (Figure 12-9).

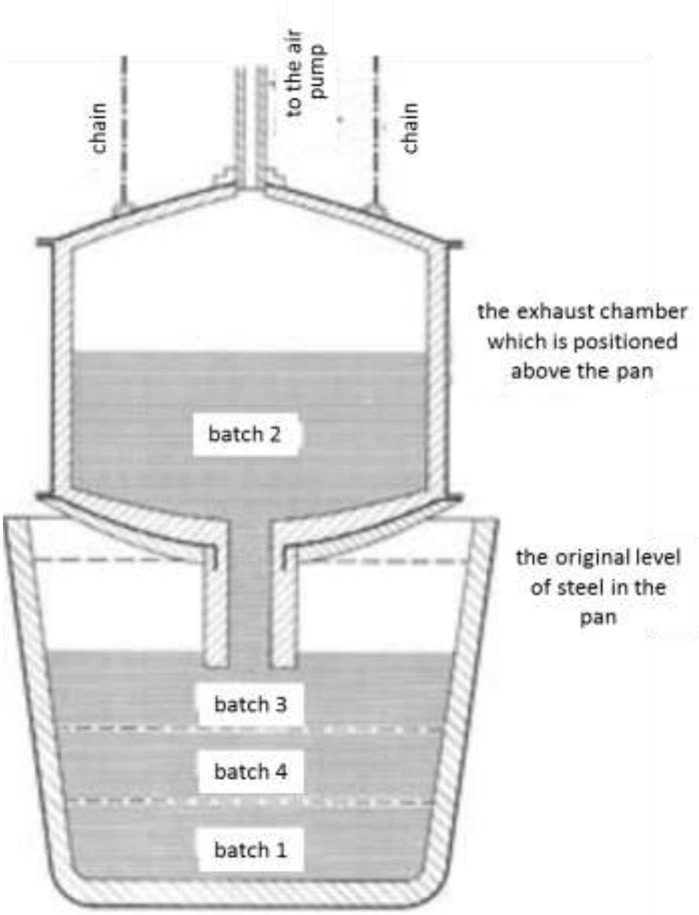

Figure 12-10: Aitken's proposal for degassing in 1882[1476]

Technical problems prevented the implementation of these interesting ideas and, at the end of the 19th century, for a special vacuum degassing unit with a casting pit. The simplest way to move the casting pit into the vacuum container after streaming and then degassing was established in 1882. A different patent from "Dellwik-Fliescher Wassergas-Gesellschaft" of Frankfurt was issued in Germany just before World War I to install a superheated liquid steam steel in superheated vacuum container. Due to the increased efficiency and better degassing, the vacuum process could be extended to several hours. Emil Fleischer (* 1843 Schwedt / Oder, † 1928) contributed to the titration methodology and gas decomposition. He provided a scientific justification for Karl Dellwik-Fleischer's method for production of water gas as mixture of carbon monoxide and hydrogen. In Frankfurt, they founded the Dellwik-Fleischer-Wassergasgesell-schaft mbH.

In 1874, 1879 and 1882, Parsons, Russel Aitken and Jensen designed a vacuum treatment of molten steel. In Germany, Aitken patented the degassing of steam and the pumping of molten steel through a tap into an emptied receiver due to the difficulties in removing gas from molten metal. He used a special container with an insulating layer for the refraction of light, and the suction hose was placed on the bottom. The container was immersed in the frying pans during alternating suction and injection of the air. Part of the melt could be sucked into a special container to gradually decompose the solution (Figure 12-10). After his patents granted all over Europe, Aitken filed US patent No. 310,012 on December 30, 1884.

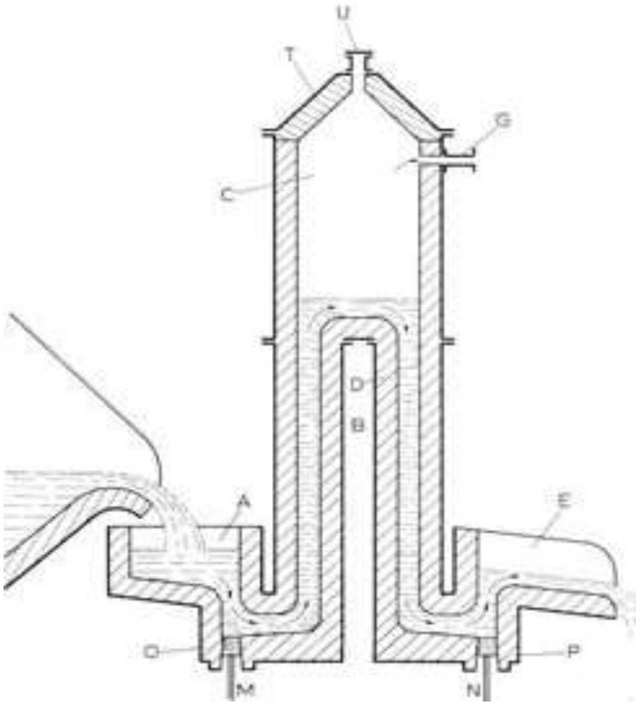

Figure 12-11: Waiwnright's proposal from 1898[1477]

On 28 January 1898 in the United Kingdom and US no 11,737 granted April 25, 1899 the Chicago civil engineer vivid antagonist of second law of thermodynamics in Parisian academician Émile Amagat’s (1841 Saint-Satur-1915 Saint-Satur) sense Jacob Tripler Wainwright (* 1854) patented the improvement of the Aitken method using two inlet pipes with liquid steel, which was the basis of

[1476] Winkler, Bakish, 1971, 343.

[1477] Winkler, Bakish, 1971, 344.

the circular process. The steel flowed through the emptied receiver continuously. Each feed pipe had a stopper, like the siphon, in the lower part. The steel was immersed in one of them to leave the degassing container later. The steel in the emptied receiver was pushed by a hydrostatic pressure due to the difference in the levels between the two baths in the stoppers shaped like siphons (Figure 12-11).[1478]

For small heat losses, an emptied receiver in a gas furnace was heated before degassing. The president of Gordon Battelle's (1883-1923) Memorial Institute in Columbus, Ohio Dr. Clyde E. Williams filled his US patent on the same foundations on March 23, 1931, while his flow of steel was increased by injection of the gas into the feed pipe. Like Aitken, C. E. Williams could re-drain the fumed iron into the original lime pan. Williams has presented concentrically placed inlet and outlet pipes. In the 1920s, many proposals for improving Wainwright's procedure were published. On November 12, 1923, J. U. Betterton patented a permanently attached emptied receiver in the melting furnace. A similar patent was received by Waldron a quarter of a century later in the United States and Britain with additional proposals for induction heating in an emptied receiver (Figure 12-12).

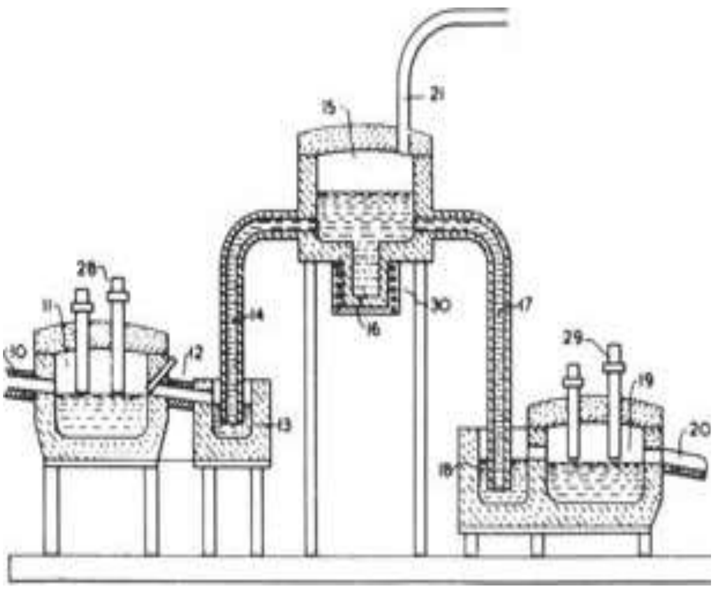

Figure 12-12: Waldron's proposal in 1949[1479]

L. Maré patented newly invented approaches to degassing in the US and Sweden on August 20, 1938. He submitted a vacuum degassing of the molten metal stream during casting or pouring. The flow of molten metal was directed to the intermediate lime pan associated with the emptied receiver. The second casting pan was placed in the same vacuum tank for receiving a stream of degassed steel. Following the laboratory experiments published between 1912 and 1953, such a procedure was chosen to begin the extensive use of degassing in industry, which was developed primarily by Bochumer Vereins in Germany and in U.S. Steel between 1954 and 1956. As the first vacuum process in the steel industry, it has accelerated further exploration of steel degassing. So far, about twenty different melting methods have been developed and tested for their use in industry. Of course, only some of them were used in the steel production: the casting pan with steel in an emptied receiver, degassing of steel current, circulating degassing and degassing during casting or after casting.[1480]

12.1.9 Separation Metallurgy (Reduction)

In 1882, after his extensive travels to Egypt and India, Dumas's student Demarçay described the extreme volatility of many metals in a vacuum. In 1905 Berthelot's collaborator the professor of chemistry in Nancy Guntz dissolved barium hydride in a steel vacuumed vessel at 900 ° C, heated it by 30 ° C and distilled the barium to 99.6% purity. In 1913 the member of AR Matignon reduced barium oxide with silicon or ferrosilicon, and MgO with aluminium at 1200 ° C. The reduced magnesium was sublimated and could be collected. Eight years later, Matignon used CaC2 to reduce $MgCl_2$ at 1200 ° C.[1481]

The use of a vacuum in separation metallurgy was investigated by DeBoer, J. D. Fast, and Van Arkel at the Philips National Laboratory in Eindhoven. In 1925, many low pressure high-temperature dissociation reactions were described using a known technique of "wire drawing" and thermal decomposition. Ten years later, DeBoer successfully tested the semiconductors.[1482]

W. J. Kroll developed a technique for vacuum distillation and vacuum thermal reduction for several metals. In 1939 he updated von Bolton-Simpson's melting furnace for reactive metals and

[1482] Schopman, 1988, 155, 167.

began to study titanium. He used water-cooled copper melting pot in a neutral atmosphere. However, this early research has also been hampered by the low demand for high-purity metals and the lack of high-performance high-vacuum devices in the industry. The development was accelerated only by the investigation of melting and casting of uranium and beryllium for the nuclear industry and the needs of aviation after magnesium.

The considerable part of the vacuum metallurgy was founded before the Second World War, and it was established after the pumps were developed in the processes of uranium separation. Since the mid-1950s, researchers of vacuum metallurgy have their separate symposia and conferences as an independent interdisciplinary research activity.[1483]

12.2 Thin Films Technologies

12.2.1 Beginnings

The thin films were first made with forging. As early as in the 18th dynasty (1567-1320 BC), the Egyptian masters of Luxor learned to forge their gold into micrometer leaves. Nowadays, we know how to scrape 0.1 to 0.05 micrometers of thick leaf, which is almost invisible from the sideview.

The copper vases electroplated with silver had been excavated from Sumerian areas in southern Iraq as part of the Baghdad museum until its robbing in 2003. An Aluminium 'Girdle' was recovered from the tomb of the Chinese Western Jin-era general Zhou Chu (Chou-Chum 周處, courtesy name Ziyin 子隱, 236–297). It was made from an alloy of 85% Aluminium, 10% Copper and 5% Manganese which could be produced only from Bauxite by an electrolytic process, after Alumina (Aluminium Chloride component of the ore) is dissolved in molten 'Cryolite'. In 500 CE the Moche of northern Peru used electricity derived from chemicals to gild copper with a thin outer layer of gold by their advanced electroplating technique. They used a very corrosive and a highly acidic liquid solution in which they dissolved small traces of gold. The copper was then inserted into the resulting acidic solution where it then acted both as a cathode and an anode generating the necessary electric current needed to start the electroplating process. The gold ions in the solution were attracted to the copper anode and cathode to form a thin layer over the copper resembling a solid gold object, even though gold only coated the outermost layer of the copper object. The Moche experts then allowed the acidic solution to boil slowly, causing a very thin layer of gold to permanently coat the copper anode and cathode.

The Europeans rediscovered those methods for applying thin films by Liebig's chemical reduction that allowed the preparation of the silver mirror layer in 1835 and by Luigi Valentino Brugnatelli's (1761 Pavia-1818 Pavia) galvanoplastic silver electroplating in 1802-1805. Brugnatelli was Volta's friend, Lavoisier's promotor and student of firmer Idrija physician Scopoli. Both techniques have been elaborated more than century and a half ago.

The modern term for specialized thin-layer technology is only used for layers built up by the processes of loading the atom onto the atom rather than by thinning a relatively large piece of matter. Thin Films are used in optics as reflective layers, filters and antireflective layers. In electronics, they are used for resistive layers, capacitors and many components in microelectronics. In mechanical engineering, they are used for corrosion protection, wear protection and lubrication. Thin Films, among other things, come in handy as useful and decorative layers on smart windows that leave infrared light in only one direction. Thin films can be prepared by electrochemical processes (galvanic application, chemical application, anodic oxidation), thermal and plasma sputtering (spray) procedures, steam phase chemical (CVD) and physical (vacuum) processes (PVD, fouling, sputtering). Prior to improvements in vacuum materials and systems in the mid-1930s, physical processes remained largely a laboratory specificity.

12.2.2 Thin Films on Glass

The glass might be among the most common materials in human environment which soon attracted the modern possibilities of designing thin films on glass to modify its outlook and other physical properties. The modern thin film coatings are applied to glasses for enhanced performance and increased added value. The coating thin films of metals or chemical compounds to glass surfaces enables a range of additional features.

[1483] Bunshah, 1994, 937–939.

12.2.3 Glassware Development

The glass was first artificially created in Asia Minor and Egypt four millennia ago. Around the beginning of Christian era the experts began to blow glass. A hundred years later the skilful Alexandrians used colored glass. The first glass windows were mentioned at the end of the 3rd century. In 1369 the art of mirror production was already known in Venice.

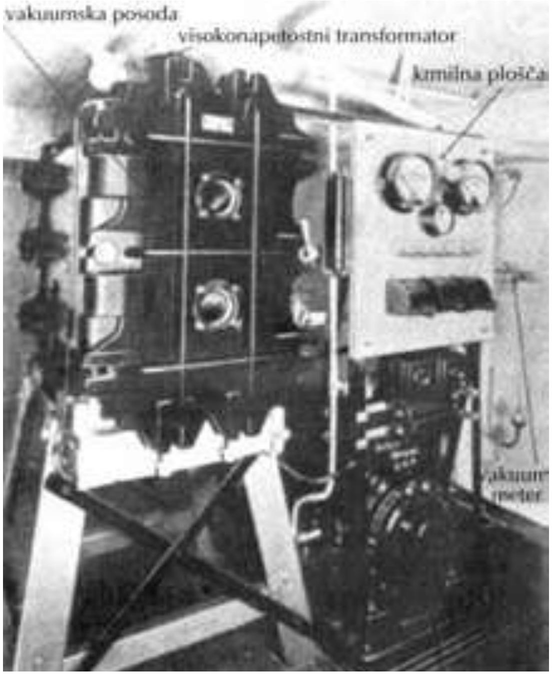

Figure 12-13: 1935 cathode sputtering production device.

In 1675, a quartz glass was found in England, which had a different refractive index due to the inmixed PbO. It enabled the dispute of Newton's theory of chromatic aberration in the mid-18th century. In 1830, Michael Faraday supposed that a common silicate glass is a liquid rather than a compound. After 1930, physicists began to study the structure of the glass, which is not in thermodynamic equilibrium, and its atomic structure is not periodic as in crystals. Thus, the macroscopic glass affected many areas at their differently achieved stages of development. Glass certainly is amorphous while its liquidity at common temperature is basically the question of preferred semantics.

12.2.4 Antireflection Coatings

In 1817 Fraunhofer first made an anti-reflex layer on glass, which he accidentally irrigated in concentrated H_2SO_4 or HNO_3. However, he did not try to use his discoveries. Only a decade later, it was explained that interference reduced glass reflectance by applying a thin layer with a smaller refractive index. Gerhard Bauer of the University of Göttingen measured the absolute values of the absorption constant of certain alkaline halide crystals on 27 November 1933. In the vacuum he poured the layers down to a thickness of about 1000 nm, which were most suitable for the measurement. The thickness of the thin layer was measured by the interference of the monochrome light.

Figure 12-14: The interior of the device in Figure 12-13. The cathode from the silver wire is intended to overlap the matrices for production of the vinyl records.

In 1935, John Strong in Caltech and later at the Hale Observatory in Caltech's Palomar, as well as Smakula from Zeiss, obtained a single-film antireflection glass coating with condensing CF_2 in glass in vacuum.[1484] In 1939, C. Hawlet Cartwright and A. Francis Turner of MIT announced that they virtually eliminated the reflectance of glass with a layer of 125 nm thickness and a refractive index of 1.2 to 1.3. The refractive index of the material could be approximated to a given value by controlling the circumstances in its evaporation. Unfortunately, the density and consequently also mechanical toughness decreased, which greatly limited the list of usable substances. They also proposed the use of multilayer overlays and eliminated refraction with

[1484] Zinsmeister, 1984, 112–113; Strong, Procedures in Experimental Physics, Prentice-Hall 1938.

Al_2O_3 and SiO_2. Many other proposed substances had excellent optical properties, but they were not resistant to mechanical and other environmental influences. The exception was MgF_2, which became water resistant after applying on hot glass substrates. In 1942, Lyon produced the first stable antireflective single-layered MgF_2 overlay on previously heated glass.

As early as in prewar year 1938, the multi-layer coatings were tested in the US and Europe. The first technically satisfactory solution was published by Auwärter with his two-layered system in 1949.

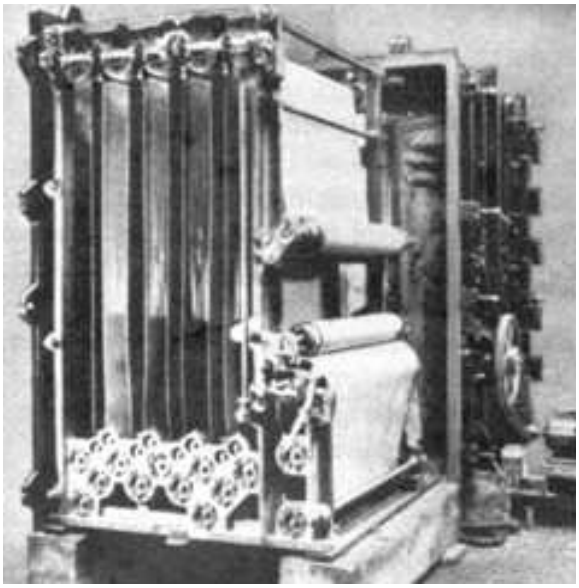

Figure 12-15: The device for covering the cords or textiles with cathode sputtering.

On 22. 2. 1946, Auwärter resigned his service at Heraeus; at the invitation of the Duke of Liechtenstein Prince Franz Josef II he joined Balzers to produce the spotted rhodium mirrors based on his patent and research published in 1939. Today they produce antireflection covering also with more than eight layers.

So, close to the places where Auersperg and Guericke once thought about vacuum the experts developed ~~by~~ important vacuum companies. Balzers has grown three hundred kilometers southwest of Regensburg, and modern Carniolan companies are also close.

12.2.5 Metal Mirrors

The high-reflection coatings were manufactured industrially much earlier than antireflective coatings. As early as 1835, Liebig reported on silver mirror layers obtained by means of a wet chemical process at the University of Giessen. Several reports have been published by researchers of light bulbs. In 1880, Sawyer and Mann described the vacuum pyrolysis of hydrocarbon vapors for the formation of thin films of charcoal. In 1897, Lodyguine studied the reduction of WCl_4 with H_2 to form thin layers of W. The first metallization process with cathode sputtering was patented by Edison in 1903/1904 for production of phonograph plates (Figures 12-13, 12-14).[1485]

Robert Wichard Pohl was the son of a shipbuilding engineer in Hamburg. He visited the Johanneum Gymnasium, as well as Franck and G. Hertz did before him. After that, Pohl studied for a year in Heidelberg, where he met Frank and then continued with his studies in Berlin. In his dissertation in 1906, Pohl dealt with the emission of light in the ionization of gases. He studied until the First World War at the Physics Institute of the University of Berlin. During the war he was involved in the development of a new radio technique as a captain. In 1916 he became an extraordinary and four years later a full professor of experimental physics and director of the Physical Institute in Göttingen, where he lived until his death. In 1979, the German Physical Society founded the Pohl Award, to award it every year. P. Pringsheim also began to research in Berlin, but after Hitler's assumption of power, he went to the US and taught in California. He studied the physics of light, especially luminescence and lasers.

In 1839 Hare first reported of the vapor deposition of thin metal layers with arc discharge in a vacuum. In 1907, Pirani patented the use of concentrated cathode rays for the vacuum melting of refractory substances, which Crookes failed in 1879. Pirani did not mention thin films in his patent applications. In 1912, Pohl and Pringsheim attempted to obtain a thin layer on a mirror by evaporation of silver, aluminium and other metals in a vacuum. They made their layers from ceramic (MgO) melting pots.[1486] Langmuir studied the rate of evaporation of

[1485] Edison, American patent no. 767216 (Zinsmeister, 1984, 110)
[1486] Mattox, 2002, 20.

metals in vacuum in 1913 and reported on his thin films.

In 1926, Ioffe's student Jew Frenkel from the Physics and Technology Institute in Leningrad published a presumption of the critical temperature of reflections of metal atoms from the substrate. In the same year, his theory was experimentally confirmed by Khartinov and Semenov at the same institution. Two years later, Semenov and his new assistant, Shalnikov, investigated the formation of a compound in the simultaneous condensation of cadmium and sulfur. In 1956, Semenov was awarded the Nobel Prize in Chemistry.

In 1928, Ritschl described a method for simultaneous silver plating of two interferometric mirrors from a tungsten-welded crucible. The thickness of the silver plating was controlled by a photometric measurement of its permeability. The mirrors were treated with HCl and HNO_3 vapors to improve optical and mechanical properties.[1487]

Rudolf Ritschl researched in a physics-technical state laboratory in Berlin-Charlottenburg in April 1931. After the Second World War, he was editor of Fortschritte der Physik.

In 1930, W. W. Coblenz and R. Stair discovered the high reflectivity of UV rays from the surface of aluminium and described the technique of evaporation of metals in a vacuum.[1488] Their discovery was completed by Strong together with Cartwright by in 1931 and on March 8, 1933 in Phys. Rev. Their method of aluminium vapor deposition is still valuable today.

Aluminium is also suitable for mirrors, because it almost repulses green light as silver, and UV is much better. Aluminium better adheres to the glass, so we can wash aluminium with water and soap without visible damage even after three months. After six months of air contact, the aluminium mirror did not lose its luster. Therefore, Strong anticipated the successful use of aluminium mirrors in UV-optics and for covering interferometric plates. Strong used a tungsten spiral on which pure aluminium was poured and then evaporated in vacuum; he exploited the limited solubility of tungsten in liquid aluminium. In 1935, a 100" telescope mirror in Palomar metallized with aluminium.[1489]

In 1933, O'Brian and Skinner deposited vapours of reflective materials for the targets of X-rays. They placed them in a graphite crucible, surrounded by a heat source in a tungsten spiral. Three years later, Umansky and Krylov studied the structure of thin films of gold and copper with electron and X-ray diffraction. DuMond and Youtz reported a decade later on a double copper and gold coating; with those layers they successfully refracted X-rays. In 1940, G. Hass patented the process of protecting aluminium mirrors with SiO_2. Between 1955 and 1965, with his research group, he introduced the technology of protecting the aluminium layer with MgF_2 or LiF layers for the UV region, while MgF_2 + CeO_2 layers were selected for the visual field. In 1944, Vekshinski investigated the physical properties of condensed layers of pure metals and compounds. He advocated the simultaneous condensation of mixtures of several components of vapors to determine their properties and phase equilibrium.[1490]

12.2.6 Hard Coatings

As always, all began with female beauties. On 19 April 1912, Jeane D Gunder first reported about the titanium nitride in powder form. He filed a patent application for a design for a titanium nitride puff box for the J A Pozzoni Pharmacal Company based in Chicago, established by Joseph A. Pozzoni 1829 England-1885 Saint Louis Missouri) in 1884. Already in 1894 Scovill's Gold Puff Box of Scovill Manufacturing Co of Waterbury Connecticut was produced for Pozzoni. In 1915 Jeane Gunder applied for another design patent for a box with fluting, scrolls and shield on the top with beading on its sides and ends as 'Pozzoni's Boodle Box,' designed for compressed or compacted powder, rather than for loose powder. In the next two decades, it was possible to synthesize more nitrides and carbides from the gas phase.

In 1893, Moissan synthesized a diamond at high pressure. Successful procedures could not be enforced for a long time. In 1911, Bolton and other

1490 Bunshah, 1994, 939.

Siemens researchers experimented to synthesize a diamond at low temperatures below 1100 ° C and low pressures below 1 bar. In this area graphite is thermodynamically stable and the diamond is metastable. However, only partial successes were reported until GE patented the process in 1954 by which they produced larger quantities of industrial artificial diamond since 1957. Soon, efforts were made to use high-conductive diamond layers in electronics. Moissan's work was soon described in the Slovene language: "Moissan came to the idea that for the artificial production of diamonds he needed the heat of an electric furnace in which the dissolved iron is impregnated by pure carbon. Then it is crystallized under the severe pressure during cooling ... pure carbon has crystallized in the shape of a natural diamond!"[1491]

12.2.7 Thin Films in the Cathode Ray Tube

With Bolton's inventions, vacuum smelting became very important tool for production of magnetic materials and particularly high-quality resistances and for the application of metals on glass of various cathode ray tubes. The photoelectron components, the transmissive and electrically conductive layers of SnO_2, began to be used for heating elements in aircraft windows during the Second World War. Other types of thin films have found use in resistors, capacitors and magnetic layers, so that electronics are today the most promising area fir the applications of thin films.

The displays made of thin liquid crystal layers have become commercially available in the 1960s. However, they were used only for indicators and alphanumeric displays, until improved material quality allowed the production of large displays. Table 12-1 presents an overview of the development of the industrial use of thin films.

12.2.8 Slovenian Thin Films

The research of thin films by galvanoplasty has a long tradition in Ljubljana. On 18 March 1856, less than two decades after the first uses of Jakobi's rediscovery of Sumerian, Moche and Brugnatelli's electroplating, Mitteis reported in detail about the history and development of European galvanoplasty for the Society of the Carniolan Museum in Ljubljana. He showed nicely decorated galvanoplastic prints in copper, reported on gilding with galvanoplasty and illustrated everything with experiments. On November 2, 1857, he explained in detail the known method for aluminium design and predicted its promising use in various crafts and arts.

In the following decades, Slovenians did not have their domestic academic environment that could follow the development of science in the world. By the mid-20th century, Slovenians studied the research of thin films in the United States only through incomplete literature available. Although thin layer sputtering was discovered in London, many pioneering researches were carried out at the universities of the Habsburg Monarchy. The Slovenians helped many discoveries; therefore, the modern research of thin films in Ljubljana has a rich tradition. The modern Slovenian systematic research began in the 1960s. Already in 1955 Saturnus began to produce parabolas for automotive headlamps with vacuum evaporation. The first aluminium filling device was purchased from the English company Edwards from Crawley of West Sussex, where they bought another high-vacuum heat exchanger in 1964. In the 1960s, Iskra-Elektrooptika (now Photon=Fotona) was founded to produce optical devices and thin-film components. Between 1974 and 1977, the Institute of Electronics and Vacuum Technology (IEVT) led by dr. Kansky.

developed the technology of producing a miniature potentiometer. The production was transferred to the Mipot factory in Krmin near Gorizia on the other side of the Italian border to suit better the Slovenian connections with the westThin layer technologies are used in Iskra's capacitor factory in Semič, Iskra semiconductors (today Semicon) in Trbovlje, in the production of metal-resistant resistors and liquid crystal displays in the former Iskra's factory Resistors (Upori) in Šentjernej and, of course, in the former Iskra's factory Microelectronics.

One of the more successful companies in the field of thin-layer technologies is Balder, which is engaged in the production of automatic protective

welding filters and other optoelectronic elements. Microelectronics and solar cells were developed in the Microelectronics Laboratory at the Faculty of Electrical Engineering in Ljubljana for almost half of a century.

In the mid-1930s, the German company Leybold developed the first sputters for industry. Two decades later, the Slovenians began to use Leybold's novelties. In 1957 at the first thematic conference at Leybold's headquarters, an association of manufacturers of vacuum coatings was established, which already had 1000 members at the beginning of the third millennium.

The most of researchers of thin films work at the Department of Thin Films and Surfaces of the Jožef Stefan Institute (IJS), especially in cooperation with Balzers. In the first half of the 1960s prof. dr. Boris Navinšek made the first simple "table" device for ion bombardment and ion etching and reported his results in the American magazine in 1965. He launched his prophetic early idea of the advantages of the sputtered protective layer over the glowing vapour depositions, which he presented at a consultation on the new methods of surface protection of the NATO Institute for the Advancement of Research in London in 1972. Navinšek's group compiled its own ion bombardment device, and the tetrode sputtering equipment Sputron were purchased from Balzers in 1978. In domestic workshops, they manufactured a cylindrical sputtering with titanium cathodes for the application of hard coating on tools. In the late 1970s, after a large investment and numerous studies, Balzers penetrated the promising market with hard protective coatings. In 1983, Balzers began to establish special research and production centers on all continents, with which Balzers secured its leading position worldwide. Balzers supported the cooperation of the Ljubljana Group, which protected the domestic thin-film technology with the patent and the trademark JOSTiN in twenty-three countries of Europe in 1983. On 18 December 1985, the Center for Hard Coatings in Domžale was opened. For their industrial purposes, they apply protective coatings with a Balzers professional device purchased with a financial support of the Slovenian engineering firm SMELT. Following the discovery of high temperature superconductivity in 1986, the research of thin films from modified $YBa_2Cu_3O_7$-x (YBCO) based on sapphire (Al_2O_3) and MgO also started on IJS. Products are used for accurate magnetic field meters. Especially useful is the MgO substrate, where it is possible to achieve a critical temperature above the boiling point of N_2 at 77 K. The Department of Thin Films and Surfaces of the Jožef Stefan Institute acquired a lot of new tools during the tenure of Slovenia minister Gregor Golobič (* 1964 Novo Mesto) in 2008-2011.

13 Analyzing Surfaces: New Materials with their Thin Films

13.1 The First Century of Auger Electron Spectroscopy for Measuring of the Composition of Thin Films - Introduction

For two centuries we know how to prepare the thin layer by electrochemical processes, while the use of physical processes of vapor deposition and sputtering is half of a century younger. One hundred years ago, Edison patented the first metallization process with cathode sputtering for production of phonograph plates. Edison's researchers used microscopes when checking filaments in their bulbs and phonograph plates, although they knew that thin-layer scanning was insufficiently accurate and unreliable. The knowledges about thin layer properties were initially far behind their production, just as the first manometers initially stayed behind the achievements of vacuum pumps. After the First World War, a useful solution was offered by Auger electron spectroscopy (AES) as an analytical technique in the chemistry of surfaces and material science. With the AES, we check the surface by measuring the energy of electrons acquired fromonly few atomic layers thick surface. The energy of the emitted electrons is between 2 keV and 50 keV. Some of them have energies specific to the elements from which they originate, but occasionally they tell us something about the binding states of the atoms.

13.2 Discovery

As with many other discoveries of modern physics, Auger's phenomenon was based on Hertz's research. A quarter of century after the discovery, Einstein correctly described Hertz's photoelectric effect. That success enabled Einstein's Nobel Prize in Physics 1921 awarded only on 9 November 1922. In that time Einstein visited Japan between 17 November and 29 December 1922 and received the award only in July 1923. He gave the money to his abandoned Serbian wife anyway.

That Nobel prize was a compromise, because the Nobel Committee members in their explanation

> **Otto Baeyer** was the son of knight Johann Friedrich Adolf, who replaced Liebig in Munich in 1873 and received the Nobel Prize in 1905. Baeyer belonged to Boltzmann's friendship circle during Boltzmann's professorship in Munich from 1890 to 1894. Boltzmann's recommendations later enabled Meitner's cooperation with Otto von Baeyer as Meitner used to be one of the last Boltzmann's students. Upon the arrival of Meitner in Berlin, Baeyer was already an established researcher of electrons. Under his father's influence, he undertook more chemical research of radioactivity in cooperation with Hahn and Meitner and lectured at the University of Berlin.
>
> In 1913, Chadwick received a scholarship entitled "1851 Research Fellowship" from the Royal Commission for the Exhibition of 1851, as did his boss Rutherford-eighteen years earlier in 1895. Chadwick emerged from a poor environment in the suburbs of Manchester; so, he wanted to spend his scholarship at home in England and save some pounds. However, the rules did not allow that, and in the autumn, he went to the Berlin Laboratory of Rutherford's colleague Geiger at Physikalisch-Technische Reichanstalt. Chadwick immediately discovered the continuous spectrum of β-rays just before the start of the First World War. The discovery was confirmed by Meitner in the neighboring Berlin laboratory, while similar research was published at the same time by Curie's Parisian assistant of Polish genus Jean Danysz in Warsaw and Paris before he became another early victim of the Great War.

deliberately did not mention the still polemical theory of relativity. In 1921, Meitner was a visiting professor at the University of Lund in Sweden where she was "cheering on" Einstein in Swedish academics' networks. She was of a Jewish family like Hertz and Einstein, and antisemitism slowly showed horns among their colleagues, especially with the Hungarian Slovakian Lenard and the Bavarian Stark onboard. She became an assistant professor at the University of Berlin just few months before Einstein received the prize. In Berlin, she attended weekly physical seminars with

Einstein, Planck, Nernst, Laue, G. Hertz, Franck, and the Viennese Schrödinger, who took over Planck's chair in 1928. Meitner had the opportunity for her experimental research, which until than had not yet been obtained by any female scientist except for a decade older Curie; so, the men wanted to listen to her opinion. Of course, she was also beautiful and unmarried.

On 29 March 1914, Einstein arrived in Berlin while his Nobel Prize has heightened interest in the photoelectricity and associated electron bombardment among the local researchers. The opportunity was best used by Meitner. She continued H. Hertz's work, begun in Berlin three decades earlier. She was interested in the β-decay process. Prior to her departure for military nursing, she and von Baeyer studied and photographed beta-rays from thorium and actinium[1492]. Similar research was published by Chadwick and Rutherford in Manchester.

The Norwegian astronomer **Svein Rosseland** from Kvam studied at the University of Oslo. During the war, the centers of science moved to neutral lands. So, at the end of 1920 he began to study at the Bohr Institute in Copenhagen, where he met Einstein. Between 1928 and 1965, Rosseland was a professor of astronomy in Oslo, and from 1954 to 1965 he was the director of the observatory at the same time.

Adolf G. Smekal studied in Vienna and Berlin and graduated in 1917 in Graz. Following the retirement of Charles Schmidt in 1927, he became a "personal" full-time professor and director of the new laboratory of theoretical physics at the University of Halle. In 1933, he announced a combined scattering of light. He obtained a real regular full professorship only under Hitler's regime in 1934 and retained it until the end of the war because he became the supporting SS member upon Hitler's enthronement and joined Nazi Party four years later in 1937. In those ugly times the Nazi affiliations helped much more than the talent. After the war he was a professor at the Technical University of Darmstadt until 1949; then he returned to Graz University and remained there until death.

Chadwick was a deeply devoted absentminded scientist: he did not read newspapers and he did not believe in any war. That's why he was surprised by the war, in the middle of his experiments in Berlin, while he suspected nothing serious. The Germans turned him overnight from a colleague into an enemy and a prisoner. After the war, he joined Rutherford in Cavendish; there Chadwick and Ellis bombarded atomic nuclei with

Wilhelm Lenz from Frankfurt by Main, studied mathematics and physics at the universities of Göttingen and Munich, where he received his doctorate from Arnold Sommerfeld in 1911 and researched as his assistant. At that time, he began to work with Otto von Baeyer. During Lenz's doctoral studies Baeyer discussed with Sommerfeld the difficulties in measuring the photoelectricity. In 1920, Lenz became an associate professor at Rostock, and in the following year he took over the chair at the newly established Institute of Theoretical Physics in Hamburg. Among Lenz's students was Ernst Ising, author of the famous model of ferromagnetism published in 1920. Between 1922 and 1928 Lenz's assistant was the celebrated Pauli, who developed a new center of atomic physics in Hamburg. As a Viennese, Pauli enabled his boss Lenz's close contacts with the other Viennese Meitner.

Wilhem Lenz (* 1888; † 1957)

[1492] Rosseland, 1923, 180.

electrons and scattered monochromatic γ-rays. In 1921 and 1923, the Frenchmen René Ledrus and Maurice de Broglie bombarded copper with the rays from radioactive rhodium. The copper ions radiated their weakly bound secondary electrons with precisely determined energies. Upon returning from war, Meitner's measured the secondary electrons, which are generated by the rays from the nuclei. Chadwick and Ellis argued that this is a continuous spectrum of β-rays. In 1922, Meitner's experiments showed that electrons depart from the bombarded nucleus at initially determined speeds specific to each type of core. The continuous Chadwick's spectrum is only a consequence of secondary influences on the electron. The question was interesting enough that Germans subsequently translated the reports of Ellis's measurements. The views of Geiger, Chadwick, Ellis and other Rutherford's collaborators on secondary electrons differed from the opinion of Berlin and Copenhagen researchers,[1493] regardless of close personal relationships between Bohr and Rutherford, and the similarity of their models of atom. The wartime dispute between Germans and Rutherford's researchers was an introduction to widespread disagreement between the summer of 1923 and December 1927, when there was a sharp exchange of views between Cavendish and Vienna on the measurements of artificial nuclear reactions and Rutherford's model of atoms.

Meitner's ideas were supported by the important young researchers of quantum theory, Rosseland and Smekal. The Viennese Smekal argued that secondary electrons fly off after a direct quantum transition without radiation. In 1922, Rosseland announced the β-ray with discrete energies, now called by Auger's name. Already before Rosseland's publication, secondary electron was discussed in German universities. Even before the outcome of Rosseland's paper in December 1922, Lenz wrote Meitner about "β-rays that emerge from a nucleus with exactly defined energies." Rosseland published his ideas on 31 January 1923, and in few months, Bohr included them in his penetrating theory of structure of atoms.[1494]

To resolve the contradictory claims and confirm Rosseland's forecasts, Meitner bombarded the target made of the isotope thorium with electrons from the radioactive isotope of bismuth in June 1923.

Lise Meitner was born in a Jewish family of lawyers, like H. Hertz did in Hamburg. Since the girls of her time were not allowed to attend gymnasium, she graduated after the private lessons. In 1902 she began studying with Boltzmann as one of the first female students of physics and the second woman who received her doctorate in theoretical physics at the University of Vienna. On 11 December 1905, she defended her doctorate on the translation of heat in non-homogeneous bodies according to Maxwell's equations. Boltzmann and Exner marked her knowledge as perfect, while the mathematician Escherlich judged that it was just enough. Boltzmann was already very ill at that times and received Meitner at his home doors; after they parted, Meitner heard the heartbreaking lunatic cries from the inside of Boltzmann's house.

Escherlich's estimates finally turned Meitner into experimental physics. Boltzmann encouraged her because he knew her problems well in his own family. Boltzmann's wife, half Slovene Jetti Aigentler, was the first student of physics at the University of Graz. Thus, Jetti indirectly greatly contributed to the implementation of Meitner, as she began with female physics education in the Habsburg monarchy. After Boltzmann's suicide, Meitner went to Berlin in 1907 where she was not permitted to Planck's lectures (Figure 13-1. At that time, Vienna lost its leading position in the experimental research of radioactivity and atmosphere, although there were no shortages of excellent researchers, among whom was Lisa's younger peer, the half Slovenian Sirk. Amongst the strict Prussians, Meitner felt even more difficult than in the cosmopolitan Vienna. The professor Fischer allowed her to research at his laboratory as soon as she promised to use the back door of the institute and never enter during the men's working time. In 1902, Fischer received the second Nobel Prize in Chemistry, but he committed suicide after the war. Immediately upon arrival in Berlin, Meitner began to work with Baeyer and most of all with Hahn (Figure 13-2). Hahn was four months younger than Meitner and he worked in Fischer's lab already for one year. Hahn and Meitner studied together over three decades and developed their own numerous scientific

discoveries. In 1912, Meitner assisted Planck, who was not so strict as Fischer against the more advanced female scientists. The following year she became a permanent member of the Society of Emperor Wilhelm. The first two military years she served as a nurse in the Habsburg army. Immediately after the war, she began to run her own group in the radio-physical institute, and together with Hahn they discovered the element protactinium. In 1926, Meitner was promoted to a post of associate professor at the University of Berlin, and two years later Hahn became director of the Chemical Institute of Emperor Wilhelm (Figure 13-2). Meitner wrote a discussion on the radioactivity at the invitation of the editor of the German Encyclopedia Brockhaus. The editor thought he was dealing with Mr. Meitner, as he only read those papers under which she was signed with the initial "L". After signing her contribution with her personal name, he realized that he was dealing with a woman. Her contribution was promptly rejected.

Lise Meitner (* 1878; † 1968)

The bombarding electrons hit the strongly bound electrons from uranium atoms. In the transition from the resulting excited state to the excited state with lower energy or in the ground state, the uranium ion delivered a secondary, weakly bound electron which was predicted by Rosseland. De Broglie's and her own experiments convinced Meitner that the secondary electron emanates from the same atom that absorbed electron of bismuth. The secondary electron, of course, was carrying a characteristic discrete energy of the atom as she intended to prove. Chadwick's presumption was therefore considered for normal beta radiation, not for secondary electrons that were predicted by Rosseland and are now called Auger's electrons. The Germans mitigated at least some of their humiliatingly lost war by correcting Chadwick's hypothesis.

Figure 13-1: Lise Meitner with Laue and Dutch physicist Dirk Coster in the mid-1930s, in front of their institute at Berlin[1495]

Meitner alone published the measurements of secondary electrons and the first confirmation of Rosseland's forecast, although Hahn and von Baeyer participated in previous research. She announced that she would continue to investigate the electron emission course with Hahn[1496] but she did not publish any subsequent studies. Researchers of radioactivity and theoreticians of the Bohr's circle did judge her research to be quite promising. It was aligned with the predictions of Copenhagen quantum mechanics while Bohr's fans were basically not interested in its use in the investigation of solid matter. In the 1920s, Laue proposed Meitner for the Nobel Prize in view of

1495 Crawford, Sime, Walker, 1997, 28.
1496 Meitner, 1923, 62–64.

her research of the beta and gamma spectra. Unfortunately, the beautiful lady never received her Nobel prize. At the same time, A. H. Compton discovered the phenomenon of scattering of X-rays at St. Louis University in St. Louis. He used a similar Bragg's experimental technique as Meitner, and in the interpretation of his discovery, he used the term photons among the first. Compton was still only a child at the time of Boltzmann's lectures in Saint Louis in 1904. He learned Bragg's technique during his studies at Rutherford's Cambridge in 1919, where he collaborated with Chadwick and the Nobel Prize winner, W. L. Bragg, before the latter took over the chair in Manchester. In 1927, he earned a half of the Nobel Prize in Physics.

Figure 13-2: Meitner with Otto Hahn in Berlin[1497]

Women, however, slowly changed science. Meitner introduced a characteristic order of a good housewife in her laboratory, thus protecting many previously unknown radiation hazards.

Many of the worst disasters were soon associated with her gender issues. With Hitler's assumption of power, the Jewish woman Meitner lost her professorship at the University of Berlin, although she was able, as an Austrian citizen, to pursue the research work of the head of the physical department of the Imperial Chemistry Institute of Kaiser Wilhelm. When Hitler annexed Austria in 1938, she had to escape. Thus, she could not sign a paper on the discovery of the fission of nuclei that she was preparing with Hahn. She secretly came to Bohr where her nephew the Viennese Frisch worked at the Institute of Theoretical Physics at the University of Copenhagen. He got married in Sweden and became a Swedish citizen in 1949. Meitner's relations with Sweden have been close since 1921, as she was an external member of the Swedish Academy. In 1960 she moved to Cambridge. The elegant lady of lower statue was able to make difficult mountain trips even at a later age. She died unmarried only three months after her longtime colleague, Hahn. In 1992, her name was used for a chemical element with the number 109. Immediately after the war, Hahn received the Nobel Prize in Chemistry in 1944. The European Physical Society has awarded the Lise Meitner Prize since 2000. In 2002 it was awarded to the professors James P. Elliot and Francesco Iachello who explored the nucleus of the atom.

Figure 13-3: The measuring devices of Lise Meitner in Berlin[1498]

The inventive research and conversations at the Berlin Physical Seminar prompted Einstein to think deeply about photons a few months after the discoveries of Meitner and Compton. Meitner reported on her discovery on 26 June 1923 in Z. Phys. Even though it was the leading German magazine, her twenty-five-year-old younger acquaintance the Parisian Auger did not read her paper in time. Thus, he discovered the phenomenon independently two years later when he was experimenting with X-ray samples for his doctorate in Paris. In 1922, Auger and François Perrin evaluated the number of electrons in the atoms by tracks observed in Wilson's cloud chamber. During the preparation for his doctorate, Auger experimented to demonstrate in the same cloud chamber (foggy cell) the entire course of

[1497] Crawford, Sime, Walker1997, 32.

[1498] Sime, 1998, 60.

excitation of gas atoms with photons: the formation of a photoelectron, the emission of quantum radiation, and the absorption of the quantum with the formation of another photoelectron. After the formation of the primary photoelectron, an additional electron was noticed at the same point. At first, he estimated that it was due to the re-absorption of the quantum of radiation in the atom from which it was derived. In 1926, during preparations of his PhD thesis the publication, Auger discovered that additional electrons were due to the radiation-free transition that Rosseland had already announced. Of course, it is a little surprising that he knew Rosseland's forecast, but not its first confirmation in Meitner's measurements. The Auger's electrons emitted by radiationless transition have energies specific to the atom they originate from. The phenomenon was named after the Frenchman Auger, not by the German Jew Meitner; the decision was both sexually and nationally prejudiced. The French tried to restore their dominance in science, and the Berliner researchers did not want to acknowledge successes of any Jews, even less the Jewesses. As a woman Meitner had many problems in her career, despite her unquestionable abilities. The Germans did not particularly fiercely support her priority efforts. Therefore, the discovery of Meitner and an additional electron included are called by Auger, as supported by a strong French school of radioactivity researchers.

Figure 13-4: Pierre Auger (* 1899; † 1993) (left) and co-worker Paul Ehrenfest (* 1916; † 1939) set up a measuring device on the hill in the Swiss Alps

In later years Auger's younger colleague Thibaud called the discovery a "composite photoelectric phenomenon." Thibaud helped Maurice de Broglie to eject Auger's high-energy electrons immediately after Auger's discovery. The French atomist J. B.

The Parisian **Pierre Auger** finished the École Normale Supérieure. Together with François Perrin they led advanced young scientists. They gathered around François's father Jean Baptiste from the University of Paris as he received the Nobel Prize shortly after Auger's doctorate. The characteristic of Perrin's school was particularly strict atomism, very like Boltzmann's School with Meitner included. After his doctorate, Auger researched at the Parisian Institute between 1927 and 1941. In 1937 he was there as a professor. In 1938 he discovered wide atmospheric Auger's lines. In the war years 1941-1945 he researched in England and in the USA. After returning to France, he was initially the Commissioner for Atomic Energy, and he was director of the UNESCO Science Department between 1948 and 1959. He assumed high administrative functions related to space research. His cosmic rays were measured on the 4158 m high glacier Jungfrau in the Bernese Alps (Figure 13-4). His colleague, Paul Ehrenfest, the son of physicist Paul, left this world after his tragic accident. In the older years, Auger also wrote about the philosophy of science. It is not known whether he regretted that he took over Meitner's priority, but they both met each other in their deeply advanced old ages.

Pierre Auger (* 1899; † 1993)

Perrin's school was particularly interested in the absorbed energy that the atom did not radiate but eject in particle form. Auger observed the X-ray diffraction of argon, xenon, and krypton, and Thibaud complemented the measurement with a similar scattering of γ-rays.

Maurice de Broglie, the older brother of Nobel laureate Louis, studied in Marseille. Between 1895 and 1904 he served as a maritime officer, and then lectured at the Collège de France until the end of the Second World War. Since 1921, his assistant was Thibaud from Lyon, where Thibaud graduated and took over the chair in 1935. During the war, Thibaud was head of the School of Physics and Chemistry in Paris, and later he returned home and led the Institute of Nuclear Physics (Institut de Physique Nucléaire de Lyon).

In 1935, the English chemist Haworth reported on his experiments with solid substances. He noticed the peaks in the secondary distribution of electrons that were not dependent on the initial energy of the incident electrons. He did not specifically deal with surface analysis, as he continued Fischer's research on sugars with X-ray structural analysis. In 1937, he received the Nobel Prize in chemistry, and ten years later he became a nobleman.

Compton's PhD student at the University of Chicago Robert Sherwood Shankland in 1935, Bohr's student Jacob Christian Georg Jacobsen of Institute of Theoretical Physics, Copenhagen in Nature, Eric Pickup of physical lab in Manchester in Nature, and Evan James Williams of physical lab in Manchester in Nature as Bohr's guest at Royal Danish Science Society, published similar experiments as Auger's in Wilson's cloud chamber (foggy cell). In 1936 and 1937, they examined the laws of conservation of energy and the momentum.

Between both wars there was already much laboratory or even industrial analysis of thin films. When the production of thin films in the second half of the twentieth century required the development of the gauges of their properties, they began to choose useful procedures. In 1953, John Joseph Lander (* 1918) of Bell Labs in Murray Hill of New Jersey linked the discoveries of Haworth and Meitner. He proved that the individual peaks in the secondary electron distribution were due to Auger's electron, which was not known to Hawroth. Lander experimented with carbon, oxygen, beryllium, aluminium, nickel, copper, barium, platinum and oxides. He was particularly pleased that most of the elements could yield typical Auger electrons with low energy from the surface layer, only a few atoms thick. The addition of one or two layers of atoms has greatly altered the results of the experiment. Therefore, he announced that the electron excitation of Auger electron signals would be interesting for accurately determining the absorption coefficients and for the formation of solid surfaces in a vacuum.[1499] Although the technique was developed for the study of surfaces, it was difficult to detect the Auger peaks; unfortunately, they were loaded onto a large background of secondary and reversed scattered electrons (Figure 13-5).

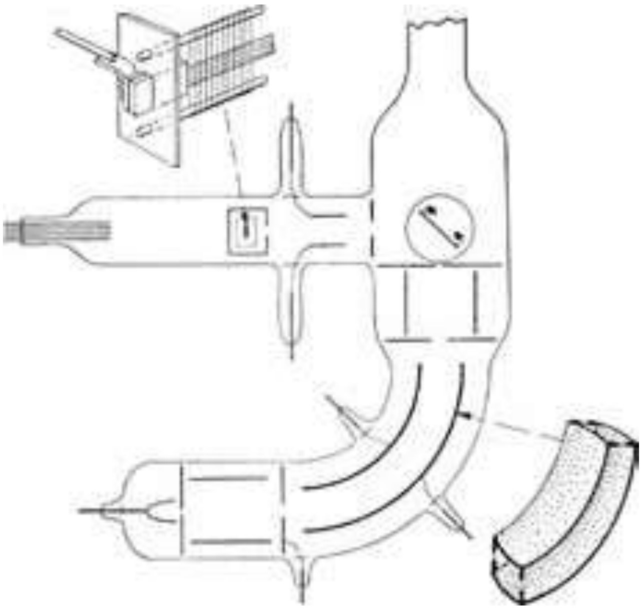

Figure 13-5: Spherical electron speed analyzer, electronic rifle and target in Lander's experiment[1500]

13.3 Application to Industry

In 1966, LN Tharp and EJ Scheibner showed that Auger's peaks can be observed in the form of a peak in the spectrum of the emitted tungsten electrons using the Low Energy Electron Leak (LEED). Larry A. Harris of General Electric Research and Development Center, Schenectady, New York presented the AES as a useful tool for

[1499] Lander, 1953, 1367.
[1500] Lander, 1953, 1383.

surface analysis next year. He showed that the use of synchrotron light enhances the spectrum characteristics that would otherwise be difficult to detect in more direct measurements. Such spectra were termed as derived spectra and after Harris's interventions became sufficiently sensitive to useful measurements.

New methods for obtaining derived spectra were soon offered by Weber and Peria with LEED. In 1969, P. W. Palmberg, G. K. Bohn and J. C. Tracy used a cylinder mirror analyzer. They achieved better sensitivity to electrons, higher speed, sensitivity and signal-to-noise ratio according to the LEED detector. The door finally opened, and we could study the chemical composition of surfaces, details of surface cleaning, gas adsorption or metal loading onto surfaces. The composition of surfaces reveals their somewhat hidden structure.

Around 1970, the AES established itself as a routine method for analysis. Today, it's the most common used method for exploring surfaces, thin films and substances on the boundary layers. It is useful for exploring surfaces 0.5 to 10 nm thick where it has good depth resolution and a suitable sensitivity of 100 ppm for most elements besides hydrogen and helium.

13.4 Auger Electrons in Slovenia

Since 1973, the researchers of Institute of Electronics and Vacuum Technology (IEVT) in Ljubljana had analyzed their samples with the AES at the Viennese Technical College or at the Max-Planck Institute of Metals in Stuttgart. Kansky encouraged his IEVT collaborators to publish their own papers. So, they had already learned about the AES method when they acquired their first raster micro-analyzer for detecting Auger's electrons in the spring of 1977. The decades of the successful use of AES in Ljubljana started (Figure 13-6).

The LEED Auger spectrometer also works on the IJS. In 1997, the Institute of Metals and Technology in Ljubljana acquired the Auger electronics high-resolution spectrometer for field emission with an X-ray photoelectron spectrometer equipped with ~~a~~ "in situ" breakage device of samples. The device offers the following options:

- High-resolution spectroscopy of Auger electrons (HRAES)
- Scanning microscopy of Auger electron (SAM)
- Scanning electron microscopy (SEM)
- X-ray photoelectronic spectroscopy (XPS)
- Spectroscopy of the lost energy of the reflected electrons (REELS).

Figure 13-6: Auger's spectroscope of PHI, SAM, 545A of Physical Electronics Inc. Minnesota in the surface analysis laboratory at the Department of Surface Technology and Optoelectronics of the IJS (until 2003 Institute for Surface Technology and Optoelectronics - ITPO)[1501]

The leading Slovenian researcher of Auger electron spectroscopy professor Anton Zalar (1943-2006) was born in the middle of World War II in Ljubljana on May 28, 1943. He studied at the Secondary Technical School, majoring in metallurgy. He graduated in 1962, and then continued his higher education at the Faculty of Natural Sciences and Technology, University of Ljubljana, where he studied metallurgy at the Department of Mechanical Engineering and graduated in 1969. After many years of work at the Institute of Electronics and Vacuum Engineering (IEVT), he enrolled at the same faculty for postgraduate studies, where he received his master's degree in 1981 and his doctorate in 1987. He was first elected assistant professor at the Faculty of Natural Sciences and Technology of the University of Ljubljana in 1992 in the field of physical metallurgy and in 1998 he became an associate professor. On October 12, 2004 he was awarded the title of full Professor of Physical Metallurgy at the Faculty of Natural Sciences and Engineering, University of Ljubljana. Until 1995, Professor Anton Zalar was employed at the Institute of Electronics and Vacuum Engineering (IEVT) and then at the Institute of Surface Technology and Optoelectronics. He was the

[1501] Zalar, 1979, 402.

longtime director of this institute while he was also the head of the Surface and Thin Layer Analysis Laboratory for over 20 years. Since 1988, he has been the leader of a research group that has conducted basic and applied research. After joining this research group within the framework of the Jožef Stefan Institute in 2003, he was a long-time successful head of the Department of Surface Technology and Optoelectronics. Professor Anton Zalar's research work focused on investigations of surfaces and thin films by Auger electron spectroscopy. He has established himself in this field at home and in international professional circles, as a valued invited lecturer at many international conferences, foreign universities and institutes. Among the great achievements of prof. Zalar it is worth mentioning the introduction of a very significant refinement of the method of investigation of thin-layer structures, which significantly improved the depth resolution in the nanometer region and enabled the investigation of chemical reactions and diffusion at the internal phase boundaries of multilayer structures. This research method is named after Professor Zalar and is still an integral part of all advanced analytical instruments for the investigation of surfaces and thin films. As an internationally recognized expert, Professor Anton Zalar managed intense contacts worldwide. Since 1975 he has successfully collaborated with the Max-Planck Institute research of metals (Metallforschung) in Stuttgart, and even with the Karlsruhe Kernforschungszentrum, Institut für Technische Physik. He has collaborated with the Institute of Technical Physics at the Hungarian Academy of Sciences, with the Department of Microelectronics at the Slovak Technical University, with the Institute of Physics of the University of Hohenheim, with the Department of Technical Physics of the University of Kaiserslautern and with the Institute of Physics of the University of Münster. The results of his research were his 360 publications, including 208 scientific and professional articles published by himself or with his colleagues in reputable scientific and professional journals at home and abroad. These works have been cited more than 1400 times, which shows us the extraordinary impact of Professor Anton Zalar's work. He has been a valued guest at foreign institutes and universities with more than forty invited lectures. For his work in the field of surface investigations using Auger electron spectroscopy, Professor Anton Zalar has twice received the Boris Kidrič Fund Award.

13.5 Conclusion

The cognition of the problems of Meitner is instructive for today's time. It is intertwined with an interesting story about the half of century that has passed from the discovery of AES to its use in industry. The discovery of early high-energy physics researchers was used in the study of solid matter. Exploring the basic laws of beta decay has benefited the industry. That is how the story links today the opposite areas and genders of researchers in physics. Perhaps the finding points of contact between them could contribute some ideas needed to solve the modern crisis of physics. The mixing of areas of research and the gender is always productive, while the mixing of different scientific traditions developed in geographically distant areas might bring even more newly developed approaches. Therefore, its high time to examine the circumstances which brought modern western vacuum technologies to the Far East.

III. Intermezzos: Export of Vacuum Design into Foreign Lands & Unexpected Uses

14 European Vacuums for Far Easterners

14.1 Hallerstein Exports Carniolan Science

The Carniolan Far Easterner Hallerstein indeed served the three masters: the Jesuits, the pope and the Chinese emperor. He also had to serve his European magnate who used to be his main financial backers. It may have been a price for a meaningful life, because Hallerstein was an important man, otherwise firmly rooted in his spiritual world. At his leading role at the Beijing astronomical bureau-office he was an all-time-superior culture broker.

According to the overall scientific work done, not only astronomical and that related to vacuum, Hallerstein was one of those famous Carniolan scientists who have left important work in the global scale far from his native blooms. He is the greatest Carniolan astronomer who has worked outside his home country. In addition to the astronomical observations, and presentations of vacuum devices to the imperial court he also participated in regulating the calendar, measuring the positions (latitude and longitude) of the places in China, and thus also in surveyors' measurement, as mapping of the vast state of China..

14.2 Vacuum Pump in Hallerstein's Beijing: Voids Allowed in the Forbidden City

Most of Chinese and even Russians love to trace the modern western technologies as the development of their own older designs. It is not easy to judge. Like in archeology which covers every detail of European soil but neglects much more sub-Saharan Africa, Latin America or Asia, all traces of early vacuum technologies are strictly researched in Europe and in ancient Hellenic frames, but not elsewhere. We are convinced that at least the Far Easterners must have had some accesses to vacuum technologies prior to their borrowings from the west; but without much decisive profs we will just try to describe the transfer of Jesuitical and Dutch vacuum equipment to Beijing and Edo (Tokyo). The Chinese historical thought welcomed the corresponding idea that modern European knowhow originated from inventions already endorsed in ancient China. Needham said that over the centuries Arab traders passed on to Europe the Chinese invention of the compass: unfortunately, there is no evidence that the Arabs knew of the compass so early. The Chinese used a wind turbine for pumping water for thousands of years before the Europeans. However, similar wind turbines occurred in Europe in 1716, twenty-three years before the first known drawing came from China to Europe, and the Swedes started to explore the Chinese models only in the 1760s.

Considering the vacuum, zeros and the infinities, the Far Easterners might have more productive approaches to those puzzles, but there is no unquestionable trace of vacuum barometers and vacuum pumps outside Europe before the middle of 17th century. For one reason or another, it took a century before those tools were officially presented to the most notable Far Eastern network in the palace of the Chinese emperor.

With the help of the superior in Canton Joseph Louis le Fevre (Fèvre, * 1706 Nantes; SJ 1722; † 1780/1783 France), the newly arrived French missionaries brought to Beijing an excellent great new reflection telescope, numerous gifts and the first vacuum pump on 12 January 1773.

The newcoming missionaries vacuum researchers were the watchmaker Méricourt[1502] and artist Panzi[1503] who traveled under the orders of French Minister Bertin.[1504] They examined the operation of the pump during their Parisian preparations for the Beijing route. Both Jesuits knew the the puzzles of vacuum techniques. On 18 January 1773, the emperor ordered the pump to be transferred to the Ruyi Guan building (Jou-y-koan), where European artists worked.

Benoist and Sickelbarth introduced a pump to the emperor in spring and explaining its operation. After the death of Hallerstein in 1779 or 1780, Le Fevre returned to Paris and personally informed Minister Bertin of vacuum successes in the forbidden city of the Chinese Emperor. Of course, the European vacuum pump has been developing in Europe for so many centuries, so that it was possible to afford a complete version for the emperor.

Benoist worked for a few months on the pump to train the Chinese for a demonstration. He explained to one Chinamen how to use it to become the helper. He selected the most interesting experiments for the emperor, got them drawn to the copperplate and explained it in a small booklet for emperor. The pump was put into place with controlled temperature to prevent any damage by the excess cold. Méricourt and Panzi have taught the eunuchs to handle the pump in order by protecting it from the colds. Their instructions were translated by Yuen-Ming-Yuen.

In the first vacuum experiments in Ru yiguan (Jou-y-koanu), four eunuchs propelled the pump on March 10, 1773. Three missionaries, the mechanics-horologer Méricourt who just arrived in Beijing, the horologer Archange (Archangelo) who arrived in Beijing in 1764 and the clockmaker Jean-Mathieu Tournu de Ventavon (Wang Dahong, Matou, 汪達洪, 1733-1787) who replaced Gilles Thébault (1703-1766) in 1766, dismantled all parts of the pump in the workshop. The eunuchs were very enthusiastic when Benoist showed them the compression, stretching and other properties of the air. At eight o'clock in the evening, the emperor requested explanations for all the experimental results. He got acquainted with the inside of the pump and the parts that were hidden in the assembled device. Benoist had to explain to him the importance of the many copper plates that were attached to the device. The emperor instructed him to repeat all the experiments of Ruyi Guan (Jou-y-koan), where the performances were prepared for him by the eunuchs.

The next day, March 11, 1773, the eunuchs reported to Benoist right after his arrival at Ruyi Guan (Jou-y-koan). They told him about the events of the previous day and about the Emperor's responses. The Emperor ordered the preparation of new experiments. Therefore, Benoist disassembled the pump to inspect if all parts were in good condition. In the afternoon, Benoist explained to the Emperor the use of various valves, large pipes put opposite to the piston, which prevents the access of external air to the pump, and an external safety valve preventing the passage of the outer air into the recipient. When the emperor was acquainted with all the parts of the pump, he asked if they could start experimenting. Preparation took some time, while the emperor asked thousands of questions, as was the custom. Benoist presented twenty-one eminent experiments to the emperor. With the first six demonstrations he proved the air pressure. The experiments followed each other. While the emperor listened to the explanation of the previous experiment, they were preparing the next one. Benoist also brought a barometer and a thermometer into the room. The emperor asked several questions about how the air reduces the mercury level in the barometer, how it raises the water in the pump, and why the change in pressure is proportional to the change in the amount of mercury. Benoist served him with explanations that were then common in Europe. He described how the density of air changes with weather conditions.

[1502] The father Hubert de Méricourt (Li Tsuen-Hien Si-Tschen, * 1. 11. 1729 France; SJ 8. 1. 1754 France; † 20. 8. 1774 Peking). Arrived in Peking on 12. 1. 1773, but died soon, shortly after Beijing vacuum experiments (Pfister, 1934, 975).

[1503] Brother Joseph Panzi (Giuseppe Pansi, P'an T'ing-Tchang, Jo-Ché, * 1734 Cremona or Florence; SJ Genova (Genes); † before 1812 Beijing) arrived in China in the year 1771 or on 12. 1. 1773 under the flag of the French Jesuits, although they already banned the Jesuits in France previously (Pfister, 1934, 971).

[1504] Henri-Léonard-Jean-Baptiste Bertin count de Bourdeilles (* March 24, 1720 Périgueux; † 1792 a health resort called Spa in then Habsburg Belgium) was the Minister of Agriculture, and in the year 1774 as well as foreign affairs. He was also a honorary corresponding member of the Parisian Academy (Amiot, 1774, 519).

The second group of Benoist experiments proved the elasticity and compressibility of the air. These experiments were very appealing to the emperor. The use of mercury in this pump may have been related to many questions about mercury that the emperor asked during the demonstration.
In Ruyi Guan (Jou-y-koan), Benoist named the pump as a "pipe for exploration of air" (yan qi tong (yen chhi thung), Nien-ki-tung in the French spelling of Chinese language). The emperor felt that the word hou (Heou in French) should be used instead of yen (Nien in French), since it is more noble, used in classical Chinese books to describe celestial observations, for observations in determining agricultural activities and changing the seasons. That is why the emperor chose the name "pipe for observation of air" (hou chhi thung, in the French record Heou-hy-tung).

At the end of the presentation of the pump, the emperor thanked his wives and other ladies for attending experiments. After prolonged presentation, during which he constantly stood near the pump, he returned to his premises and instructed the servants to take the pump along with him. Benoist, Méricourt and Panzi were richly endowed with three large pieces of silk.[1505] The following year, Benoist died from a stroke just a few days before Hallerstein, who was twelve years his older. Panzi later painted the great emperor's portrait.[1506]

We do not know the type of vacuum pump that Minister Bertin sent to the Chinese Emperor. At that time, Hauksbee's pumps from the beginning of the century still dominated. However, in 1721, Swedenborg[1507] assembled a new type of pump. He used a table with two tall legs holding a closed bell. The steel vessel was connected to a steel tube through which mercury poured.

In 1721, Swedenborg designed a new series of pumps that Žiga Zois studied in his enormous books, which he had brought to Ljubljana. Dr. Joseph Knight Baader (* 1763; † 1825) used similar Swedenborg receptions in 1797 as a substitute for Marly's pumps in Versailles in 1806. The principle was used by Joseph Baader in his improved pump, followed by the Frenchmen Michel and Cazalet. Most of the contemporaries did not know Swedenborg's discovery, so Gren[1508] reprinted it and commented on it.[1509] In 1847, Strutt baron Rayleigh published a translation of Swedenborg's discussions under the title Principles of Chemistry in London, and ten years later Geissler in Bonn used Swedenborg's principle for pumping the first cathode-ray tubes.

So, Bertin could send to Beijing Parisian pump of Michele or Cazalet; but they were probably still a kind of novelty in 1772. Cazalet also reported on solidification of mercury in Bordeaux in 1779. The freemason Jean-André Cazalet (1753 Anglès-1825 Bordeaux) was a pharmacist in École centrale in Bordeaux where he taught physics and chemistry at the university in 1796 and 1819.

The well-deserved candidate for the Parisian authorship of the minister Bretin's Beijing packet was Jean-Antoine Nollet. In 1740, Nollet published on vacuum pumps and discussed them in his letter to other inventors of pumps like Jean Jallabert (1712-1768) in 1745 and to the physician-electrician François-Étienne Dutour de Salvert (1711 Bailleul (Nord)-1789 Riom) in 1746. Nollet preferred Dutour's simpler design of vacuum pump. Most of the vacuum pumps of that era were designed by the illustrations of later Nollet's textbooks.[1510] Certainly, Musschenbroek's designs were also praised, as most of Musschenbroek's books were also translated in French language. Even as late as in the 1770s the instruments following Musschenbroek's design were still produced by Georg Friedrich Brander and his son-

in-law Caspar Höschel (1744–1820) in Augsburg.[1511]

Nicolas Thillaye (1709 near Lizieux-1784 Rouen) was a father of the heir of his manufacture Noël-Vincent Thillaye (1749 Rouen-1802 Val de la Haie), of a botanist Jacques-François-René and a physician Jean-Baptiste-Jacques. Nicolas Thillaye acquired royal privilege for his production of pumps. He published his manual for constructions of vacuum pumps in 1766.[1512] He was a well-deserved descendant of Pascal's merits in the same town of Rouen. His design might be the one which the minister Bertin passed to Bejing, except that Nicolas Thillaye manufactured his tools in Rouen and not in Paris which was the alleged source of the vacuum pump delivered to the Chinese Emperor in 1773.

The assistant to Jean-Charles chevalier de Borda (4 May 1733 – 19 February 1799) Étienne Lenoir (1744–1832) also manufactured scientific instruments including the repeating cycle for geodetic surveying in Paris.

As the French Minister Bertin sent a vacuum pump designed in Paris to Beijing, he may have consulted the later most important Parisian pump manufacturer Fortin,[1513] a staff member of the Parisian office of lengths (Bureau des longitudes) established in 1795. By Lavoisier's initiative Fortin began experimenting on balloons and precise balances. In 1778 and 1779, he presented his own vacuum pump to the Parisian Academy, where he first used a double stroke in France. In 1784, he compiled a gas meter, and in 1788 very accurate scales for Lavoisier. He invented a highly successful mobile barometer filled with mercury. After Lavoisier's execution, Fortin's laboratory was sold out on 10 November 1794. During the Empire, Fortin was involved in the production of scientific tools, and in 1806 he produced a gauge for exploring the expansion of air.

The Chinese emperor most likely got Nollet's or even Fortin's Parisian pump, designed for the needs of the Lavoisier's circle. Fortin's vacuum pump had two pumping mechanisms. They directed the chain with hooks, pushed in opposite directions by means of a lever. Both pistons were connected by Fortin to reduce the force required to overcome air pressure. The idea was developed earlier. Fortin linked both pistons as did Denis Papin (* 1647; † 1713), Francis Hauksbee (Hauksbee, Hawksbee, * 1660 Colchester; † 1713 London) and P. Musschenbroek's colleague Willem Jacob 'sGravesande (* 1688; † 1742). The Beijing missionaries equipped 'sGravesande's book with the proprietary entry of the Franciscan treasurer Alexandre de Gouvea (* 1731 Evora in Portugal; † 1808 Beijing), who was designated as the Bishop of Beijing in 1782.[1514]

Two inlet pipes originating from the pump body were merged into one, open in the middle of the horizontal plate for vacuum container. Pressure on the container was transmitted through the test tube on the side. It worked on a tube containing a "squeezed" siphon barometer with the same legs. The barometer measured small pressures by difference in mercury levels in both arms. The remaining pressure in the barometer can be measured with a vertical tube mounted on the second side opening, with the end immersed in a full mercury container. When the pressure in the vacuumed vessel decreases, the mercury in the tube rises. The pipe in front of the plate releases air into the container, which would otherwise be impossible due to air pressure. In the later version, a second barometer and a small lateral faucet were added to it, through which the gas was discharged into the previously prepared container.

Anyway, the Chinese Emperor was very fond of the French vacuum pump. François Bourgeois described the Peking experiments with the pump in a letter to the French Jesuit Duprez on November

1, 1773 and November 29, 1773.[1515] Bourgeois' research of the Shanghai dialect was later published in Shanghai (1934, 1939); his work was probably sent to Paris together with Hallerstein's survey of Chinese population statistics by which Hallerstein shocked Europeans who figured out that the great stone nicknamed earth was not entirely theirs at all.

The vacuum pumping was not over for Chines after the Beijing era of Jesuits. The Vincentian (Lazarist) monk expert for vacuum pumps, magnetism and electricity Jean Joseph Ghislain (1751 Salles by Chimay in Habsburg Belgium-1812 Beijing) arrived in Beijing in 1785 following Amiot's recommendations of Vincentians (Lazarists). Amiot wished that Ghislain and his Vincentians could take over the Jesuitical heritage in Beijing. The Bishop of Beijing, Alessandro de Gouvea, invited Vincentians (Lazarists) to Macao in China. In 1811, the Chinese emperor expelled from Beijing all but three Portuguese Vincentians (Lazarists) who were members of the Bureau of Mathematics and the French Vincentian (Lazarist) Louis-Francois Lamiaux, who was the French interpreter at the court. Ghislain died in Beijing several months later anyway.

The Chinese have accepted the assumption of air pressure like Europeans did a century earlier after Torricelli's letter to Ricci, when most Jesuits preferred to read Aristotle's interpretation of their Belgian Jesuit of English genus Linus, or Nicolo Zucchi's (* 1586; † 1670) Jesuitical work Nova de machinis philosophia with antiperistasis and fear of emptiness.[1516] As the Chinese got their vacuum pump after the European controversy about the reality of vacuum was more or less settled down, they had not much ideological problems while voids were never very strange to the people of China or India anyway. The Easterners certainly influenced all European ideas of infinitely smalls as even Guericke himself cited mainly from Kircher's description of the universe,[1517] and he quoted also Huygens, Keckermann and Valeriano Magni who all heard a lot about Fareast at their domestic European harbours.[1518]

The Calvinist Barholomew Keckermann (* 1571/1573 Gdansk (Danzig); † 1609 Gdansk), despite his premature death, figured as a very important physicist.[1519] The Beijing Jesuits afforded two (1649 and 1669) editions of Zucchi's book with the proprietary entry of the Hallerstein's house as the seat of Chinese province (Prou[ae] Sinensis).[1520]

Even Descartes and the profound admirer of the Chinese Leibniz rejected the Torricelli-Galilean vacuum. The Chinese Jesuits used Galileo's[1521] works including the Italian edition published in 1718 in Florence, which was acquired by Hallerstein's friend, the Bishop of Nanjing Laimbeckhoven.[1522] Also, Hallerstein read Torricelli's[1523] mathematical works with his comrades; they merely used the humanistic part of Leibniz's books,[1524] and numerous Descartes' books including Optics and Geometry.[1525] The Pekingese Jesuits tried to save some coins, so some of Galileo's works in their possessions were bound together with Philip Apian's De utilitate trientis (1586. Tübingen), Kepler's Dioptrice (1611), Giulio Cesare La Galla's (Lagalla* 1570; † 1624) De phenomenis in orbe lunae new telescopi usu a D. Gallileo Gallileo (1612. Venetiis: Thomam Balionum), the Florentine Franciscus Sitius' (Sizzi, Firenze-1618 Paris) anti-Galilean Dianoia astronomica (1611. Venetiis: Peter Maria Bertan),[1526] A. Piccolomini's peripatetic Parafrasi sopra le Mecanica d'Aristotle (1582, Roma), and others. Hallerstein read even a suspicious Galileo'sDialogue (1632, Florence), but preferred the translation of Matthias Bernegger issued in 1635,[1527] because Hallerstein as the obedient guy feared to use the later forbidden Galileo's Discorsi.

Sumitomo later used the Leiden Latin edition of Dialogue of 1641 in Japan.[1528]

Hallerstein and Laimbeckhoven used the German edition of Bion's Mathematical School[1529] and Wolff's Elementa matheseos universae on their way to the Far East in (1732-1735);[1530] both contained a description of vacuum pumps and they were also very popular among the residents of Ljubljana.

14.3 Hallerstein's Vacuum Related Books and Tools

14.3.1 Introduction: Books also Like to Travel, Do they Not?

Tell me what you read, and I'll tell you who you are ... That ancient proverb certainly fit perfectly to Hallerstein, who has brought the reputation of Carniolan knowledge to the undisturbed, never exceeded highs of the Chinese Celestial Empire. Hallerstein brought over the seas to Beijing a Slovenian songbook of the priest Stržinar. Hallerstein used to be a Jesuit pupil in Ljubljana and Vienna, and, above all, a great descendant of the Jesuits of St. Francis Xavier (* 1506; † 1552).

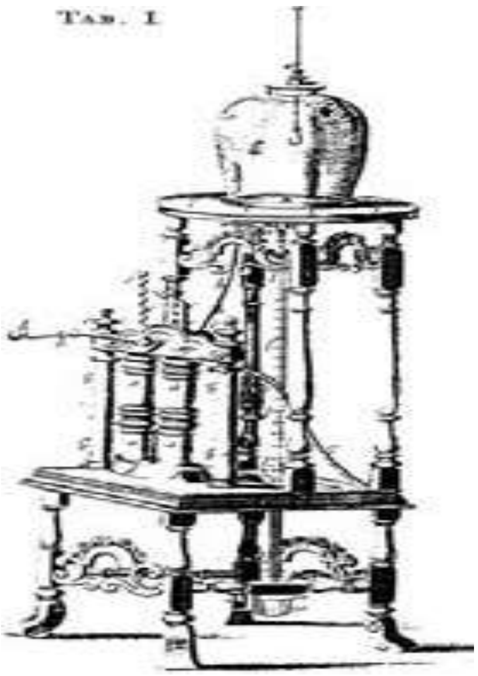

Figure 14-1: Hauksbee's vacuum pump from 1719 (Hauksbee, 1719, Tab X)

Foreword to the songwriter Stržinar was written by Franc Mihael Paglovec (* 1679 Kamnik; † 1759 Spodnji Tuhinj). Unfortunately, Hallerstein did not record his personal inscription on a bookplate into that and other books, although his predecessors, the Jesuits in Beijing's leading positions, did that regularly.

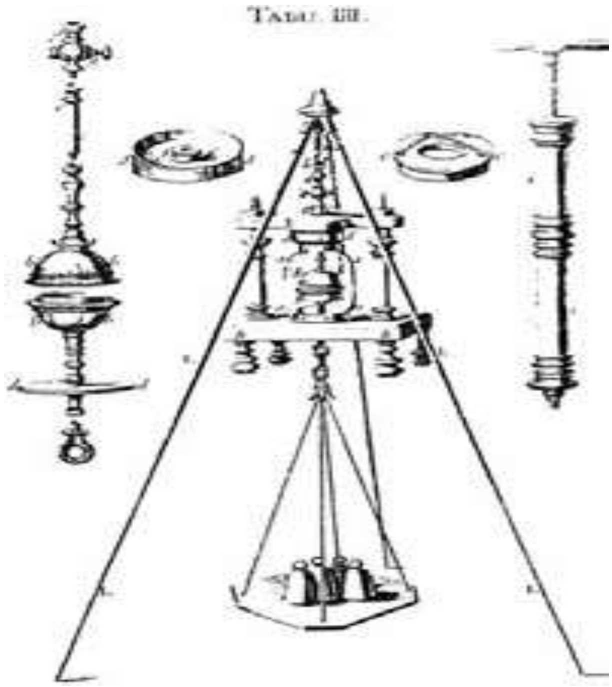

Figure 14-2: Hauksbee weighing of air pressure by the Magdeburg hemisphere of 1719 (Hauksbee, 1719, Tab IIII)

Hallerstein was the head of the Tongt'ang library in the second Beijing residence established under the Portuguese flag in 1655, half a century after the first Nant'ang library. It was founded by Ricci and was among the best of all Beijing missionaries' collections.[1531] So, we have a lot of books with the proprietary entry of the Nant'ang library, often written as Nan-tâm. That certainly indicated Hallerstein's ownerships. Among Hallerstein's readings there were many gifts of Parisian scientists, as well as the legendary Boerhaave's collection of medical writings in the Venetian edition. Many Hallerstein's books had the seal of the respective bishop of Beijing, among whom only Jesuit Souza and Gouvea lived in the bishop's seat at Nant'ang headquarters near Hallerstein's residence.[1532] For this reason, most Hallerstein's books have the bishopric own proprietary records. In the case of Souza, often only his name

Polycarpe was used as a propriety entry. The first edition of London printed Smith's Optics from 1749 shows that the bishop handed the book to Hallerstein. Many Hallerstein's books had merely the mark of his collegium "Collegii S.J. Pekini" with the modern French works included.

After Hallerstein's death, all Chinese missionary libraries merged into a library of former French Jesuits called Pe-t'ang.[1533] Many mathematical works in the Latin language have the bookplates of Bishop Gouvea, who may have put them only afterwards, as he took over his bishopric only eight years after Hallerstein's death. Hallerstein's predecessors mentioned themselves as the Chinese vice-provincials and as Japanese provincials' dignitaries, but Hallerstein did not do that anymore, although he became vice-provincial and visitor of Japan in 1745. The Japanese Jesuitical books got their Japanese Jesuit proprietary entries only prior to 1665, since the Jesuits have no longer been allowed to visit the Land of the Rising Sun after 1640.

Hallerstein published his highly detailed observations[1534] in important European metropolises. He never put his foot on the Japanese soil. Except for the foreigners of the Dutch Verenigde Oostindische Compagnie (VOC) on the artificial island of Deshima (Dejima, 出島) in the Nagasaki bay, no foreigners were permitted to put their anchor in Japan after 1640.[1535] Hallerstein has learned his science as assistant Ignatius Kögler and André Pereira (徐懋德, 1689–1743).[1536] He continued the development of the mathematics of the French Pekingese Jesuits Gerbillon, Bouvet, and Thomas[1537] by re-establishing co-operation between the two groups of Jesuit missionaries who worked under the flags of Portugal and France. Hallerstein was especially close to the French Jesuits Gaubil, d'Incarville and Amiot. If there has ever been a serious competition between the two groups, Hallerstein had abandoned it by the time when the sharing of scientific devices and the exchange of knowledge became increasingly necessary for Beijing's Jesuits, while their core activity was inextricably shifting from religion to science in fatal decades before the ban of their Jesuit order.

Hallerstein has repeatedly tried to convince his European correspondents about his insufficient supply of astronomical and physical aids. In his own right, that was primarily a smart policy for acquiring better equipment, with which, as a conscientious observer, Hallerstein also earned his knowledges of natural phenomena. Hallerstein's European correspondents in London and elsewhere accepted his explanations, helped him and sent new devices and books for astronomical and other observations in a kind of exchange for Hallerstein's Chinese measurements.

14.3.2 Hallerstein's Ljubljana Scientific Background

The Magdeburg Mayor Otto Guericke sold one of his first pumps to Schönborn, who, as a prince and bishop, of course, was very wealthy; in Regensburg he was impressed by Guericke's experiment with horses, which in vain tried to separate the evacuated hemispheres. Even the emperor Ferdinand III was excited about the funny experiment of unsuccessful horses.[1538] After Ferdinand's death, Johann Philipp von Schönborn (* 1605; † 1673) played a key role in the election of his son, the emperor Leopold, under the influence of the Prince of Ljubljana Janez Vajkard Auersperg (Johann Weikhard Auersperg, * 11 March 1615, the town of Žužemberk; † 1677 Ljubljana), the informal first minister at the Viennese Court. Auersperg helped Guericke in his vacuum experiments,[1539] as Avgustin Hallerstein later read in Guericke's Amsterdam report of 1672 under his Beijing bookplate ownership noted as "Collegii Societatis Jesu Pekini".[1540] A. Hallerstein's mother, Susana Elizabeth, Baroness Erberg (* 1681 Ljubljana; † 1725) was the granddaughter of Auersperg customs official Lenart von Erberg (Leonard Verderber, * 1606; † 1691 Kočevje) from the Knežja Lipa in Kočevje areas, and therefore Hallerstein with even greater pride, read about the Auersperg's achievements; maybe Hallerstein liked it even more than we do today. Hallerstein became acquainted with vacuum

and electrical experiments already in his native city of Ljubljana, where the first prince Turjaški (Auersperg) spent his last years. Auersperg's associate Guericke closely linked his vacuum experiments with his invention of an electrified spinning ball of sulfur. The first prince of Auersperg was not only Guericke's "assistant", but also a great supporter of science; he had richly awarded the Roman Jesuit A. Kircher, who dedicated the chapter from his Oedipus to the prince; moreover, the prince gave a golden cup to the Protestant Johann Wilhelm Count Stubenberg (* 1619 Neustadt along the Mettau River in the east of the Bohemian Lands; † 24. 4. 1663 Kitsel in Hungary or 15. 3. 1663 Vienna) for his translation of F. Bacon's book.

Stubenberg devoted to the prince Auersperg the first German translation of Francis Bacon, a prophet of the modern-day growing importance of applied science and experiments. For this reason, Auersperg presented a splendid golden cup to Fruchtbringende Gesellschaft in 1657;[1541] Stubenberg was its member under the imaginary sad name "Unhappy."

On his visits to Carniola and Bakar bay, Newton's patron Halley enjoyed the guiding of Hallerstein's father also in the time when Hallerstein was born in Ljubljana. With such an excellent base, Hallerstein had something to show to the Chinese Emperor for whom he worked in the second half of his life. Even before he threw out his anchor in Canton in September 1738, he learned all about the latest electric experiments of Stephen Gray (1729), Charles François de Cisternay Du Fay (1732) and Du Fay's protegee the Priest Jean Antoine Nollet, who later transformed into the main rival of Freemason Benjamin Franklin. Hallerstein paid close attention to the work of Cisternay Du Fay because of his name sounding like the Cistercian, as two of Hallerstein's younger brothers were successful Carniolan Cistercians: Abundius Hallerstein († 1768) proved to be amongst the best local Cistercians, and Alexander Hallerstein († 1804 Ljubljana) became the last abbot of the Kostanjevica monastery and witnessed the sad story of its abolition in 1786. The Chinese somehow accepted Hallerstein's astronomy including the electrical devices and vacuum pumps, as Hallerstein and colleagues in their Beijing libraries had three copies of the description of the Jesuit vacuum balloon of Lana Terzi,[1542] and they also read about Montgolfier's balloon. The Jesuit Hallerstein scanned the entire opus of Pascal,[1543] although the man was bitter against the Jesuits and ridiculed the quarrelsome Jesuit Étienne Noël.[1544] Hallerstein read the physics writings of Schott,[1545] Newton and Musschenbroek[1546] already in the library of his uncle Franz Michael Baron Erberg (* 1679; † 1760) in Ljubljana and Dol; there he liked to look at the barometric experiments of Laurentius Gobart (* 1656 Liége; † 1750 Liége) from 1716 and 1746, while Hallerstein also provided essentially the same reading in Beijing. Hallerstein has learned electrostatics and vacuum techniques already in Ljubljana, where his role model Auersperg has spent his final years. The first cousin of Hallerstein's mother, the Jesuit physicist of Ljubljana Bernard Ferdinand Erberg (* 1718 Ljubljana; † 1773 Krems), procured vacuum and electrical devices in 1755 at the latest, and at the same time the Brits, Dutchmen and Sanchez mailed them to Benjamin Franklin in Philadelphia,[1547] for Hallerstein to Beijing and for the Shogun to Edo (Tokyo). We discovered how Hallerstein and his Beijing colleagues tested vacuum and electricity and, above all, achieved enviable successes.

14.3.3 Beijing Experiments with Electricity

The magnets were the first love of Carniolan Hallerstein, since he already measured the compass

[1541] Bircher, 1995 *The "splendid library"*, pp. 289, 297.

[1542] Lana's books were decorated with the proprietary entry of the French Pekingese Jesuits "*PP Gallor SJ Pekin, Collegij Societatis Jesv Pekini, Veyo da Residenca de Cinanfu*" (Lana Terzi, *Magisterium*; Verhaeren, 1996 *Catalogue*, pp. 572-573) and with Hallerstein's "*Da Vice Provinciae da China da Compania de Jesus, Collegij Societatis Jesv Pekini, Vice Provinciae Sinesis*" (Francesco Lana Terzi, Prodromo, Brescia, 1670; Verhaeren, 1996 *Catalogue*, p. 971). The French Pekingese Jesuits also decorated reports of research on the vacuum in the mercury barometer of Torricelli's heirs at the Academy of Florence, edited by Count Lorenzo Magalotti (* 1637; † 1712) under the title Saggi di naturali esperienze (Verhaeren, 1996 Catalog, p. 921 (No. 3136)). Equal Bookplates have Schott's books: *Magia universalis, Mechanica (1657) and Physica Curiosa* (Verhaeren, 1996 *Catalogue*, pp. 804-805 (Nos. 2717-2719)).

[1543] Verhaeren, 1996 *Catalogue*, p. 150.

declination while navigating to the Far East. Later he completed his findings in Beijing,[1548] where they acquired the books about the Jesuitical theories of the magnets of Nicolo Cabeo (* 1586; † 1650) published in his Philosophia magnetica[1549] and the thoughts of the Chinese Flemish Jesuit Ferdinand Verbiest. They dominated over today's more conceivable assumptions of the doctor of British Queen, William Gilbert,[1550] although already the partner of Chinese Jesuit superior Nicolas Trigaut (* 1577; † 1628) Johann Schreck (Terence, Terrentius, * 1576 Constance; † 1630 Beijing) brought Gilbert's book De Magnets (1600) to Beijing.[1551] By inscriptions on the bookplates, we can easily identify the books of other Jesuits in Beijing. Unfortunately, Hallerstein did not even enter his name in Stržinar's songbook,[1552] although we could search with a candle on a white day for anyone other than him who could read it in Slovenian language in China. Certainly, some books from the once Jesuit Beijing libraries got their feet in the forthcoming century or came to the hands of less consecrated owners.[1553]

In 1750, Hallerstein and his associates from the Portuguese college of St. Joseph in Beijing received an electric device, along with aids to observe the eclipses. The Jewish doctor Antonio-Nunes Ribeyra Sanchez (Ribeiro Sanches, * 1699 Penna-Macor; † 1783 Paris)[1554] obtained both those instruments with his friends in London and the Netherlands. In 1740, the designated Bishop of de Souza[1555] assisted in transport;[1556] for the time being we do not know for sure the type of Hallerstein electric machine, as we cannot be sure about the whereabouts of an electric device which Erberg bought five years later for the Jesuits of Ljubljana. It could probably also be a spindle producing its electrical power supply by friction after Guericke's invention, and not the Leyden jar, which Pieter Musschenbroek's invented in November 1745. The description of the novelty was published in January of the following year. Formerly a Leyden University student, Sanchez learned hourly about P. Musschenbroek's novelty, as he attended P. Musschenbroek's lectures at Leyden University. P. Musschenbroek's father and uncle established a shop for vacuum and electrical appliances right across the street. Sanchez regularly corresponded with Gerard van Swieten; Swieten's comments on their joint teacher, Boerhaave, were translated by the Japanese,[1557] while they were no less enthusiastically read by the Beijing Jesuits.[1558] Unfortunately, love was strongly unilateral, as both Swieten and his friend Sanchez soon deleted the Jesuits very badly.[1559]

Even before Sanchez delighted Hallerstein with an electric device, the rich Quaker Peter Collinson (* 1694 Hugal Hall in northwest England; † 1768 London) sent a Leyden jar from the London royal society to Benjamin Franklin across the Atlantic. In 1751, Collinson arranged for the publication of their correspondence, which largely defined modern thinking about electricity and lightning rods.[1560] Sanchez also corresponded with Collinson; he sent him the seedlings of rhubarb, which he received from Hallerstein's Jesuits.[1561]

On October 25, 1753, Collinson sent a flower of mimosa to Hallerstein's good Beijing friend, the

French watchman and the imperial gardener Pierre Noël Chéron d'Incarville (* 1706; † 1757).[1562] On 2 November 1747, d'Incarville reported to the Parisian Bernard Jussieu (* 1699 Lyon; † 1777 Paris) that Hallerstein gave him Johann Schreck's herbarium Plinius Indicus with plants, minerals and animals harvested in nature at a happier age when the Ming's authorities allowed the Jesuits to move freely across China and neighboring countries. Gabriel Gruber's Jesuit relative the father Johann Gruber (* 1623; † 1680) described Schreck's book to Kircher, and Kircher summarized it in his book on China,[1563] which was read by everyone from Valvasor in Bogenšperk to Hallerstein in Beijing. Schreck created his own collection according to Hernandez's Mexican model as Galileo's colleague at dei Lincei's Roman academy where Schreck assisted its founder Federico Cesi (* 1585; † 1630) in the Roman publication of the Hernandez' Notes Thesaurus Mexicanus, published in 1651. Unfortunately, Schreck's collection which Hallerstein kept in secret after Kögler's death in March 1746 did not receive a similar fate in print and is now considered to be lost. Hallerstein was aware of Schreck's activity, since Kepler published Schreck's letter in his optics Ad Vitellionem in 1604, which Hallerstein inherited from the missionary Alexandre de Rhodes (* 1591; † 1660 Isfahan in Persia);[1564] unfortunately, the forger's mare is always barefooted, so that the first-ever connoisseur of the plants from all the continents, Schreck, poisoned himself with the vegetal weld after his wrong fatal belief that it was a jasmine. Hallerstein allowed his friend d'Incarville to copy Schreck's herbarium for d'Incarville and Jussieu's use, so there once were at least three copies of Schreck's manuscript. D'Incarville sent the transcript to Jussieu in three letters dated in 1747, 1748, 1751; Jussieu handed the collection to Claude-Joseph Geffroy (* 1685 Paris; † 1752 Paris), who died before he was able to finish comparisons with previously-known European plants.[1565] In February 1746, Secretary of the London Royal Society Cromwell Mortimer asked the Chinese Jesuits to send him butterflies and their larvae; for this purpose, Hallerstein assigned his friend d'Incarville as the best Jesuit connoisseur of plants in the capital, as he reported to Mortimer in a letter dated September 18, 1750.[1566] Thus, Hallerstein has gained immense merits among biologists as well including his research on Siberian musk deer (*Moschus moschiferus*) published in London.

The leading Chinese European scientist Hallerstein also held his hand over the famous Beijing experiment with electricity, which is largely the basis of a modern electronically-oriented society. His associate from the French Jesuit College, Amiot, was also thrilled to experiment with electricity, but Hallerstein had much better equipment, as it was slightly jealously reported by Hallerstein's French Jesuit comrade, Gaubil.[1567] At that time Amiot, Hallerstein and Hallerstein's assistant Gogeisl measured the apparent height of the Gamma star in the constellation Andromeda for comparison with similar measurements carried out by Jesuit Pezenas[1568] and his two assistants in Marseilles.[1569]

Beijing's electrophorus, described in the letter to the Petersburg Academy in conjunction with the invited competitional academic prize, was an achievement of Hallerstein's social network, which was highly praised by the Russian academics in anticipation of new Beijing-based Jesuit electricity

[1564] The Pekingese Jesuits had two heavily cited copies; one designated by Rhodes as his property in Macau: Alexi Rhauds J.C. D.M.Ch. (Verhaeren, 1996 Catalog, p. 557; Pfister, 1934 Notices biographiques, pp. 184-185), like that of the Venetian edition of the ancient Heron (Heron, De gli automata, Verhaeren, 1996 Catalog, p. 968). At the end of the year 1646 in Macao (Macau) the Pole Michel Boym (* 1612; † 1659), named "Miguel Polaco", was noted and immortalized in Kepler's tables (Kepler, Tabulae Rudolphinae) full of manuscript remarks with a inscription of the bookplate: *Da Livreria de Nant'am. – Memoriale ao p^{e} Procurador de Japon. Pede muyto o P Miguel Polaco que ste livro Tabulas Rudolphinas V R(esi)detencia en Procuradoria e si o mesmo P^{e} Miguel Polaco ditto liuro pedira a P^{e} Joan Nicolao de China que o mande lae si ambos merveran que a appliqué pera Pekin porque he unico a optimo pera calcular as Ecclipses Sol et Luna e movimentos dolle 1646. Decemb 2. Maccaj* (because he is the only one to calculate the eclipses of sun and moon with movements, Verhaeren, 1996 *Catalogue*, p. 559).

research. In 1755, the Pekingese Jesuits fused a thin glass plate and placed it on a compass glass cover so that the charging could be repeated several times. Each time the magnet needle rose again and returned to its original position in a few hours. When the Jesuits withdrew the previously-charged glass panel, the compass's magnetic needle rose again and remained in contact with the glass cover. When they returned their glass plate to its previous place, the needle dropped again. Thus, the Pekingese Jesuits could repeat the experiment many times.[1570] They were certainly not fully aware that for the first time in history in a controlled laboratory environment they observe a repeatable experiment with a permanent source of electricity, as we have been used in today's batteries or electrical outlets. But they were sufficiently self-conscious to report their success immediately to the Petersburg Academy, which soon accepted Hallerstein as its correspondent (foreign) member as the only Catholic of Slavic origins besides Bošković and Janez Žiga Valentin Popovič.

In November 1753, the Petersburg academy of science published a prize-winning question about the real causes of electricity and its theory, and the last day for mailing the answers was June 1, 1755.[1571] The Russians were interested in both physical and chemical backgrounds of electrical phenomena.[1572] We do not know whether the competing contribution of the Hallerstein's Jesuits came in time to Petersburg, but despite of all the praise they were not officially rewarded. According to the contributions of other competitors, it might be possible to say that the exploration of the Pekingese Jesuits was primarily a careful experimental observation, as was also typical of all Halletstein's contributions, while the winners of the competition also provided a more philosophical explanation of the background of electrical phenomena.

On September 6, 1755 the Russian Empress Elizabeth proclaimed the winners. The first prize (praemio coronato) was awarded by the academy to the son of the renowned academician Leonhard Euler, the young Johan Albrecht Euler (* 1734; † 1800), for his Disquisitio de causa physica electricitatis. L. Euler's works naturally got the most prominent site of the Hallerstein's Library. The other two selected studies were created under the goose pen of the Barnabite monk Paul Frisi (* 1727; † 1784) from the University of Pisa[1573] and Lalande's Jesuit professor, director of the astronomical observatory in Lyon employed in 1740 Laurent Béraud's (* 1703 Lyon; † 1777 Lyon) *Physique des corps animés*. The victorious works of the triumphant trio were announced by the Academy in 1757, while the copy of their book was also noted among the collections of a Pekingese bishop Alexandre de Gouvea (* 1731 Evora in Portugal; † 1808 Beijing) in 1782; by his pleasant habit, he pressed his seal on the cover.[1574] The Beijing missionaries also obtained a later Frisi's study of electricity published in 1781,[1575] although Frisi opposed Bošković's Jesuitical Lombardian pedagogy. Frisi also participated in discussions on magic in the circles of Koper native Gian Rinaldo Carli, who became the leading Lombardian economist soon after the commission installed Bošković in then Habsburgian Pavia University. Carli wrote his introductory letter of his Lettere Americane to the freemason Benjamin Franklin, and the collection was printed in 1781 by Lorenzo Manini, another Freemason in Cremona.[1576] The electricity testing was thus extended from the Hallerstein's Pekingese Jesuit circles to the main fun of the European Freemasonry networks where it was advanced by Franklin's friend, the Parisian Freemason[1577] and Swieten's successor in the profitable position of personal physician of Maria Theresa, Jan Ingenhousz (Ingen Housz, * 1730 Breda in southern Netherlands; † 1799 Wiltshire). On his way to Florence in May 1769, Ingenhousz visited the provincial headquarters in Ljubljana and explained to the Carniolans ~~of~~ the benefits of vaccination against the smallpox.[1578] In the same year in 1769, Bošković and Franklin's friend, the Piarist Giacomo Battista Beccaria (Beccheria, * 1716 Mondovi; † 1781 Turin), reprinted a report on the electric experiments of Hallerstein and his

companions interpreted by Franc Aepinus.[1579] Beccaria offered a satisfying explanation; Beccaria was initially very close to the young Alexandro Volta and led him to his new discoveries that enlightened the world. Literally, by electric lighting.

14.3.4 Hallerstein's Vacuum-related Books

The bookshelf is the most important mirror of the human soul. This is especially true for astronomers. Since we do not yet have the portrait of most important Carniolan astronomer Avguštin Hallerstein, we can see at least the contents of his books on the anniversary of his pilgrimage to China, where he soon climbed into the very top of Chinese astronomy. He never returned to Europe, and his absence was outweighed by his published works in all major European centers.

The Beijing bishop Gouvea often provided enough early entry dated propriety entries, but Gouvea himself came to Beijing too late to directly cooperate with the nearly three decades older Hallerstein. That is why we will limit our listing of Hallerstein's books to those works that Hallerstein certainly used shortly after their printouts. They were marked by the ex libris of his college in Beijing, but some books, unfortunately, were left without a bookplate.

Among old books from Hallerstein's library were Claude Rabuel's (* 1669 Pont-de-Veyle; SJ 1685; † 1728 Lyon) Lyon comments on Descartes's geometry and Jean Jacques d'Ortous de Mairan's interpretation of the northern light (Aurora Borealis). Both books got the bookplate of the Hallerstein's Beijing College in 1739, a few months after Hallerstein's arrival in China on September 1, 1738. After Hallerstein settled in Beijing on March 1, 1739, maybe he himself marked the ownership record in both those books. Mairan's work, which Hallerstein had read only six years after the Parisian print, was especially useful to Hallerstein during his own observation of the northern light (Aurora Borealis) in Beijing on 17 September 1770, which Hallerstein described for a publication of his friend Hell in Vienna a year and a half later.[1580] Mairan was a close Bošković's associate and briefly secretary of the Parisian Academy. Unfortunately, Hallerstein, by his very nature, confined itself only to the observation of the northern light without any possible theoretical interpretations; so, he did not cite Mairan's nor Bošković's papers about the northern lights, although he must have known them. In 1733, Hallerstein's Viennese associate Maximilian Hell and four decades later the former Ljubljana rector Anton Ambschell still accepted the Cartesian belief that the northern lights is due to the reflection of the solar and even the lunar (mirrored) light on ice particles under the horizon; we can think that Hallerstein could not be too far from their opinion. The autumnal 16th-18th September 1770 Northern Lights besides Hallerstein, also Hebei province observers, the Japanese, and Hell also afforded to observed. It became certainly the most famous in all Auroras in history when it appeared after long decades of absence of these phenomena; the Captain J. Cook, as the first, watched it with modern scientific preparations on the southern hemisphere and proved that the southern hemisphere aurora australis also had similar colors as the aurora borealis had on the north.[1581]

Hallerstein began to read the professor of mathematics Rabuel's critique of Descartes's geometry nine years after its publication. He echoed the Jesuit controversy of those years when even a physical fight between the Cartesians and their opponents broke out at the Zagreb college; it was only calmed down by a strict intervention by the Jesuitical authorities. Four years before the publication of Rabuel's book in Lyon, just before Hallerstein started teaching rhetoric in Ljubljana, the Italian professor of physics Anton Terzi of Gorizia, with the help of the professor of logic Josip Novoselić from Varaždin publicly defended theses in 1726 and appealed to General Tamburini reject Descartes' presumption on accidents that should remain in the Eucharist. Descartes' ideas were advocated by the professor of metaphysics Luka Bakranin; Terzi and Novoselić criticized him with the help of his own students.
Bakranin entered Cartesian networks during his studies in Graz and in Vienna; he did not hide his Cartesian views horses when he became professor of philosophy in Zagreb in 1723. The dispute stirred the whole city. By the intervention of the

Austrian provincial Maximilian Galler the Jesuitical general Michelangelo Tamburini tempered the unfortunate inconvenience by scolding both sides. Terzi (Tertia) was rejected by noting that Descartes's works had not yet been placed on the list of prohibited doctrines in official index on 15 June 1706. The clever general of the Jesuits recalled that Bakranin had asked him earlier to go to the missions; after the dispute in Zagreb, of course, he granted his request mercifully. Unfortunately, the poor Bakranin died while waiting for a boat in Cadiz.[1582] He was born in Oštarije 20 km south of the White Carniolan border while his surname suggested his connections with Bakar bay forty km west of his native place.

In the meantime Hallerstein replaced the very painfully ill and next spring deceased Kögler, In 1745, Hallerstein wrote the ownership record of his college in the seven years old astronomical and physical work of Joseph Nicolas Delisle (d'Isle, Lisle, * 1688 Paris; † 1768) which Delisle personally donated to him before returning from the long-standing Petersburg astronomical service to his native Paris. In 1749, Hallerstein, now officially anchored at the highest scientific position possibly filled by a foreigner inin Beijing, acquired the most prominent optical work of his time, the eleven-year-old London publication of Robert Smith (* 1689; † 1768), which was also read by the Jesuits of Ljubljana. Hallerstein's book was acquired in the Nant'ang College by the Jesuitical Beijing bishop ~~of~~ Polycarpe de Souza. Gabriel Gruber, the first Ljubljana teacher of astronomical observations, bought Smith's optics in Pazenas' French translation from 1767 with the addition of Bošković's description of achromatic lenses; in 1772 Gruber entered a characteristic property registration of his department "Zur Mechanic"[1583] in the book in Ljubljana. Much later, the wealthy Sumitomo in Japan preferred the German translation of Smith from the pen of Gruber's teacher Abraham Gotthelf Kästner (* 1719; † 1800), which was published in 1755.[1584]L. Euler was, of course, the main source of Hallerstein's astronomy and related disciplines. Therefore, in 1745, the Russian Academy gave to Hallerstein two L. Euler's books about motions and music. Undoubtedly, they served him very much even if he did not read the other two Eulerian pearls owned by the Bishop Gouvea later.

The Neapolitan Jesuit Nicola Gianpriamo personally donated his astronomical textbook to Hallerstein and the Beijing Jesuits in 1748. According to the year of Dian-Griam's death, we can assume that a kindly gift was carried out shortly after the publication of the book; as an astronomer, of course, Hallerstein used the book with pleasure. Hallerstein was undoubtedly regularly reader of the Parisian Academic Bulletin, as were his Beijing neighbors under the French flag. Hallerstein's knowledge of French language was not the best, but it was enough for reading; he was especially pleased with volume containing the article under the pen of his French comrade d'Incarville from 1755, which Hallerstein's companions labeled as the property of his Beijing college called Nant'ang in that same year.

The Parisian pocket physical manual of the Jesuit Aimé Henri Paulian (* 1722; SJ; † 1801) of 1760 does not have proprietary entries, but it was probably also included as the everyday reference tool at Hallerstein desk. The bishop Gouvea later had the same work besides Pauilian's adaptation of La Caille's mathematical papers, and many other La Caille's astronomical works.

Lalande's astronomy from 1771 was brought to Beijing at a time when Hallerstein's powers were waning; that book too was left without a proprietary entry. Lalande's works were, of course, read much by his French Jesuit fellows in Beijing. Lalande's ephemeris was even collected by the Beijing bishop Gouvea. Of course, the leading freemason Lalande may have been relatively far from Hallerstein's view of the world, but in their approaches to astronomy they were soon close enough. Lalande's Parisian Masonic Lodge the Four Sisters (Neuf Seurs) also had a greater impact on the inhabitants of the Habsburg monarchy with Slovenes included, as among its members was the imperial personal physician Ingenhousz,[1585] as well as his friend and co-worker in the expert in exploration of gases and getters, Felice Fontana, who joined the Habsburgian court of Florence as a

teacher of physics of the sons of the later emperor Leopold II.[1586] Bošković's friend Franklin was, of course, one of the key personalities of Lalande's Lodge, and he benevolently showed himself at the ceremony of accepting the elderly Voltaire on 7 April 1778.[1587]

By the travel notes of his companion and friend Gottfried-Xavier Laimbeckhoven (Nan Hoai-Jen Ngo-Te, * 9. 1702 Vienna, SJ 27. 1. 1722 Vienna; † 22. 5. 1787 Tangjiaxiang by Songjiang east of Shanghai (T'ang-kia-hiang pi Su-choua) in China), we proved that Hallerstein brought to China at least the books of Claude François Millet Dechales (* 1621 Chambéry 100 km east of Lyon; SJ 1636; † 28. 3. 1678 Turin),[1588] Georg Fournier (* 1595 Caen; SJ; † 13. 4. 1652 La Flèche), Christian Wolff (* 24. 1. 1679 Breslau; † 9. 4. 1754) and Nicolas Bion (* 1652; † 1735). Unfortunately, the recent inventory of the former Beijing missionary library does not say anything conclusive about the fate of these books of both loyal comrades, Hallerstein and Laimbeckhoven. So, we do not know for sure where these works were kept later. They–were published in folio formats, most of all Bion's encyclopedically-oriented treatment of mathematical and astronomical measuring devices. It is likely that the pathetic youngsters loaded earlier versions of Bion in their travel bags; that Parisian maker of mathematical devices was so popular in Ljubljana that Žiga's younger brother Karel Zois chose his work even as an ad ligate to his final exam at the University of Graz soon after Hallerstein's death. To the publications from the time of Hallerstein's life, we also added Stržinar's songbook, which does not have any astronomical pretensions, but it offered a tremendous amount of consolation to the great astronomer in the nights when the astronomical measurements did not come entirely as expected.

The Jesuitical naturalized Parisian Georges Fournier did not exactly love the Roman astronomers; nevertheless he praised Kircher's early measurements of the lunar eclipse of August 28, 1635.[1589] Even before he began to read Fournier's Geography in Beijing, Hallerstein certainly saw it together with other Fournier's works in the Ljubljana library of the princes of Auersperg who used to be the masters of the ancestors of Hallerstein's mother, the noble baroness Erberg.

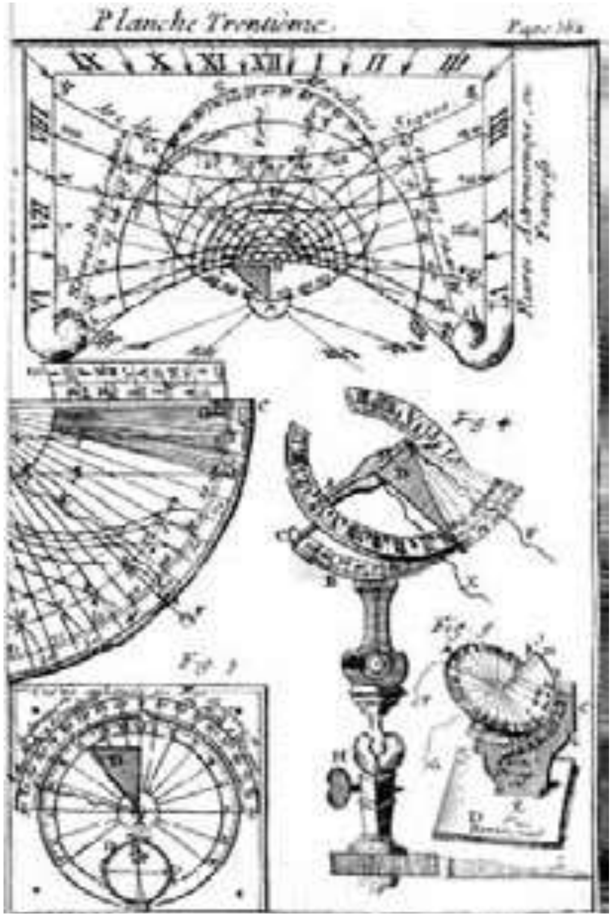

Figure 14-3: Gnomons in Bion's Descriptions of Mathematical Devices (Bion, 1752, 338 (Plate 32))

The Chinese Jesuits used Galileo's works[1590] up to the Florentine Italian edition of 1718, purchased by Hallerstein's friend, the Bishop of Nanjing Laimbeckhoven.[1591] Of course, Galileo was formally the antagonist of most Jesuits; but the different views of the world never hindered Hallerstein's use of Galilean astronomical and physical knowledge. The seemingly strict Papal bans were increasingly weakened by the distance from the eternal Rome.

The French Jesuit Claude François Millet Dechales (* 1621 Chambéry; SJ; † 1678 Turin) in his Cursus considered the researches of light of Mersenne and Maurolyco.[1592] Bouguer's Traité was published

barely in the aftermath of 1760 with a famous sketch of a photometer, resembling Dechales's drawing in Cursus from 1690.[1593] The Chinese Jesuits afforded both Dechales's editions with his critical remarks at the expense of contemporaries; they were printed in Lyon in 1674 and 1690, and they were greeted with the proprietary entry of the Chinese provincial in Beijing; Hallerstein himself added to his many duties the honor of the Chinese vice-provincial in 1745. Hallerstein and Laimbeckhoven used Dechales' manual as a guide to triangulation during their sailing to the Far East. They probably loaded a newer edition from 1690,[1594] while Hallerstein, as a student and teacher in Ljubljana, used the older first print of 1674; the Jesuits of Ljubljana entered their ex libris into it as early as 1678.[1595] Dechales' manual is today the oldest preserved once-Jesuits' book in NUK with dated bookplate eventually connected with the year of purchase; Hallerstein read it already during his studies in Ljubljana and then during his teaching in the Carniolan capital. Dechales published, among other things, useful tables of logarithms up to 10,000, which facilitated Hallersten's painstaking prolonged astronomical calculations.

Hallerstein and Laimbeckhoven also brought with them to China the German edition of the Bion's School of Mathematics from 1726,[1596] and Wolff's General Cosmology in many new volumes printed between 1732-1735; both books did not lack any descriptions of astronomical devices, vacuum pumps and other modern devices. Wolff's General Cosmology[1597] had a proprietary record of Hallerstein's colleagues Kögler, Andre Pereyra and Karl Slaviček in the library of the Beijing College as a gift from the Petersburg Academy. It was brought to Beijing by the leading Russian academician of German descent Teophil (Gottlieb) Siegfried Bayer (* 1694 Bohemian Lands; SJ; † 1738 Petersburg) upon his visit to the Russian Beijing mission.[1598] Bayer was a correspondent of Hallerstein's French associate Dominique Parrenin (Parennin, Pa To-ming K'e-an, * 1. 9. 1665 Grand-Russey; SJ 1. 9. 1685; † 20. 9. 1741 Beijing).[1599] According to the year of publication and Bayer's death seven years after the print, Wolff's work was placed in the Hallerstein College Library just before Hallerstein's arrival. In his domestic college, Hallerstein read another famous Wolff's work, the Fundamentals of General Mathematics in two different editions.[1600] Hallerstein and Laimbeckhoven used one of these two Wolff's textbooks of Basics of General Mathematics during their sailing in the Far East, beginning with their stay in the port of Lisbon on 24 April 1736; we assume that they have afforded the latest edition to brimg as much as possible modern news for their Chinese hosts. Wolff's Element or Compendium from 1743 and 1744 were kept at the Ljubljana lyceum and in the library of Cistercians in Stična. The Ljubljana lyceum also had the printout issued in 1776. In them, Wolff considered trigonometry as the third chapter of mathematics after for arithmetic and geometry. At the end of his trigonometry, he briefly described the logarithms with which Neper and Briggs translated the multiplications and divisions to the additions and subtractions even for sinuses and tangents. Wolff also described the logarithms of ordinary numbers and provided the table for them.[1601]

Hallerstein has, of course, already learned all about Wolff's works in his domestic Carniolan headquarters. In the late Baroque, the Franciscans of Novo Mesto (New City) taught along Leibniz's guidelines; for this purpose, they bought many Wolff and Sturm's works including their adaptation

Figure 14-4: Wilde's Lyceum books Census (1800) showing Wolff's Compendium of 1744, which also Hallerstein afforded in Beijing.

Hallerstein was keenly impressed by Wolff's explanations already while reading the books of the Jesuits of Ljubljana, even more so on visits the private library of his maternal uncle Erberg. The libraries were, of course, linked closely as the Jesuit College of Ljubljana and its books were largely led by Hallerstein's relatives, mathematicians, astronomers and physicists of the family Erberg. Hallerstein's uncle baron Erberg classified many Wolff works from his Jesuitical Ljubljana library into a mathematical class, in which he also put the astronomical books. At least some of these Wolff's textbooks were examined by the student Hallerstein and then again while he taught in Ljubljana:

1718. Ratio praelectionum Wolfianarum in mathesin, et philosophiam universam. Halle / Magdeburg. 8^{o}.

1725. Anfangsgründe aller Mathematischen Wissenschaften. Frankfurt. 1-4. 8^{o}.

Hallerstein, as a genuine Slovenian mountains' son, in his traveler bag brought Stržinar's songbook to Beijing. For many decades that book comforted and consoled him as the sole chorus of the Slovenian word far around. Two centuries later, a Beijing librarian the Lazarist Verhaeren mistakenly placed it among Polish books[1603] in simple ignorance, since the Slovene language was an unknown foreign language for poor Verhaeren. The reading of Stržinar's rhymes is at the same time the most beautiful proof of Hallersten's Slavic linguistic abilities. Even if Hallerstein surname has some German connotations, Hallerstein remained the devoted Slovenian also among the Chinese far from his birthplace.

Boerhaave's collected medical works from 1757 have an explicit note as bookplate of the Hallerstein College of Peking, since Hallerstein liked to look in it for medicines explicitly noted for his health problems. Swieten was, of course, the most important scientist in the Hallerstein homeland, the Habsburg Monarchy. Nevertheless, the Beijing whereabouts of Swieten's comments on the work of Swieten's teacher Boerhaave is less certain; its older Venice print of 1746 does not have a proprietary entry, but there is also no proprietary entry in Stržinar's songbook, which had been Hallerstein's faithful companion until his last busy hour.

Hallerstein's friend d'Incarville was an important supporter of Linnaeus; the Viennese edition of the Linnaeus system was relatively late, and

[1602] Lind, 1992 *Physik im Lehrbuch*.
[1603] Verhaeren, 1996 *Catalogue*, p. 1203.

Hallerstein could read the earlier prints of Linnaeus's works[1604] in the headquarters of the French Jesuits. Hallerstein's contribution to the botanical sciences of Linnaeus's sorts was of utmost importance, although we have just recently presented it to the Slovene public.

14.4 Habsburg-Slovenian Vacuum for the Far East

Only a few Jesuit missionaries from the Habsburg monarchy worked in China; they were very influential anyway. From the Austrian Jesuit Province, the Czech Václav Pantaleon Kirwitzer, Koffler, Johannes Gruber, Diestel, Herdtrich, Fridelli, Messari (Mesar), Joseph Chrysostom Neugebauer, Laimbeckhoven and Hallerstein traveled successively in China. Diestel, Mesar and Hallerstein were Carniolans, while Andrew Wolfgang Koffler was teaching Rhetoric in Ljubljana just before he sailed to the Far East. One of the most important Chinese missionaries was the Tyrolean Martino Martini, but Tyrol with Trident, Innsbruck and Hall was part of the Upper German Jesuit province.

Thus, the Carniolan guys contributed a substantial part of the Chinese missionaries from the Habsburg monarchy. Koffler and Martini went to the East before Torricelli's and Viviani's pioneering vacuum experiment, but Martini temporarily returned to Europe from 1650 to 1658 to research both Italian and German achievements. J. Gruber's traveling companion Vipava native Bernard Diestel studied physics at the University of Graz in 1643/44, when Torricelli wrote his famous letter to Ricci on the first barometer.

14.5 Early Japanese Vacuum Techniques

14.5.1 Introduction

Guericke sold one of his first pumps to Schönborn, who, as a prince and bishop, of course, had enough money; in Regensburg they impressed him with horses, which in vain separated the evacuated hemispheres. Even Ferdinand III talked about the experiment with enthusiasm. Johann Philipp von Schönborn (* 1605; † 1673), after Ferdinand's death, played a key role in the election of his son, Emperor Leopold. Those novelties gradually spread worldwide as the Chinese have somehow accepted Hallerstein's astronomy and the novelties about the vacuum pump.

[1604] Verhaeren, 1996 *Catalogue*, p. 600.

14.5.2 The Dutch Science Travels to the Habsburg Monarchy (1713-1795) and to Japan (1720-1853)

The Catholic part of the Netherlands, in the approximate borders of modern Belgium and Luxemburg, belonged to Habsburg monarchy Luxemburg, belonged to Habsburg monarchy from the peace in Utrecht (July 13, 1713) until the French invasion (1795). At that time, the Belgian scientists, mostly after the study at Boerhaave's class in Leyden, exported Dutch science to a somewhat backward Habsburg monarchy. At the same era, translators from the Dutch language named Rangaku arranged that science for Japanese after the partial release of Japanese imports of books in 1720. Thus, the Musschenbroek's Leyden vacuum technique was approximately simultaneously established among the Japanese as among the Slovenes.

Dutch physician the Freemason Ingenhousz transferred vacuum techniques to Vienna, and his compatriots did the same thing in Japan through the Deshima Island in Nagasaki Bay. Before10th and again on 20th August-9th September 1772, in the then Habsburg Firenze Ingenhousz vaccinated against the smallpox the family of archduke, the later Emperor Leopold; in Galileo's city, he was hanging out with his friend Felice Fontana,[1605] On his way back to Vienna until 28th in May 1769 he visited the provincial centers of Trieste, Gorizia, Ljubljana, Klagenfurt and Graz and explained there to the local surgeons and physicians the benefits of vaccination against the smallpox.[1606]

Fontana allowed Ingenhousz to describe the invention of Fontana after Ingenhousz returned from Vienna to England in 1782.[1607] Ingenhousz used a vacuumed vessel with a copper and brass

[1605] Wiesner, 1905a, 37.

[1607] Wiesner, 1905a, 72, 197; Ingenhousz, 1787, 197-198, 200, 228.

Priest **Felice Fontana** (Felix, * April 15, 1730 Pomarolo near Rovereto in Tyrol near Rhône-Alpes, † 11. 1. 1805 Florence) never preached unlike his brother the Piarist mathematician Gregorio. Felice studied in Verona and Pavia. Then he lectured at the University of Pisa, where he became a professor of physics in 1766. He became famous enough; so, the Tuscan Archduke Leopold appointed him as director of the Physical and Natural History Museum in Florence. In 1772, Felice Fontana discovered the adsorption of gases by the heated wood needed for charcoal burning. He stopped the combustions of charcoal and at the same time prevented the outflow of the outside air to maintain the adsorption power of charcoal; later, he placed it in a vacuum receiver to absorb undesired air there. The count Marsilio Landriani (* 1751 Milano; † 1827 Vienna) described Fontana's discovery to J. Priestley, who repeated the experiment in 1775,[1608] but both Ingenhousz and Bošković were in heavy quarrels with Priestley. The Swedish expert Scheele (* 1742; † 1786 Köping) as one of the discoverers of oxygen successfully set the experiment for Scandinavians in 1773, while Bryan Higgins (Bryan, * 1737? Sligo in Ireland; † 1820) also confirmed Fontana's discovery for the great benefit of vacuum techniques in 1776. Priestley attended B. Higgins lectures and bought some tools from him, but they later quarreled, as B. Higgins soon also became estranged from his nephew William Higgins who first enunciated the law of multiple proportions. Fontana even thought that his charcoal could adsorb the volume of air that exceeded its own volume by six times;[1609] he performed the tests in a mercury barometer with a tube of 35 inches long. He filled about 10 inches of length with measured volume of ordinary air, hydrogen, nitrogen or oxygen to be able to observe changes in the adsorption power of charcoal. He measured the additional amount of matter that he withdrew from the already emptied space to reduce its density by his experiments with nitrogen.[1610]

cap. He did not fully endorse Fontana's hopes that his getter of charcoal exhausts a better vacuum than ordinary pumps.[1611] Today, you might just give the due praise to Ingenhousz's doubts. Fontana's method of gettering was prepared for the technical analysis of gas mixtures using a hand-held eudiometer in a procedure resembling Cavendish's experiments. At the same time, he improved Fontana's oxygen inhalation device,[1612] later used by Thomas Beddoes in Bristol[1613] in the merry company of Žiga Zois's friend H. Davy. In 1771, Felice Fontana and Ingenhousz wrote about scientific devices and plans for the establishment of Academy of Sciences in Florence.[1614]

After studying at Boerhaave's class in Leyden, **Jan Ingenhousz** (Ingen Housz, * 1730 Breda in the south of the Netherlands; † 6. 9. 1999 Wiltshire) happily accepted the invitation of Maria Theresa to become her personal physician. Later, he somewhat regretted that decision because he felt trapped in Vienna and could not travel without permission. So, he asked his friend Benjamin Franklin to plan his leave for America although in 1775 he married Agatha Maria Jacquin (* 1735), the sister of the famous Viennese professor of botanic baron Nicholas Jacquin; or maybe just because of that? Ingenhousz discovered photosynthesis, and he designed many vacuum and electrostatic experiments for the study of various gases. During his trip from Vienna to Florence he also visited Carniolan places).

Ingenhousz returned to Vienna after three years of travel. He mostly stayed in Fontana's Florence.[1615] As soon as he recovered from a clumsy journey along the badly paved roads, he built a double-piston vacuum pump in Vienna using Fontana's discovery of charcoal getter's absorption. That kind of research was later highly appreciated by Ernst Mach,[1616] who often visited his parents under Gorjanci in Lower Carniola (Dolenjska). Ingenhousz used a powder mixed with olive oil to hermetically seal the vacuumed vessel;[1617] he

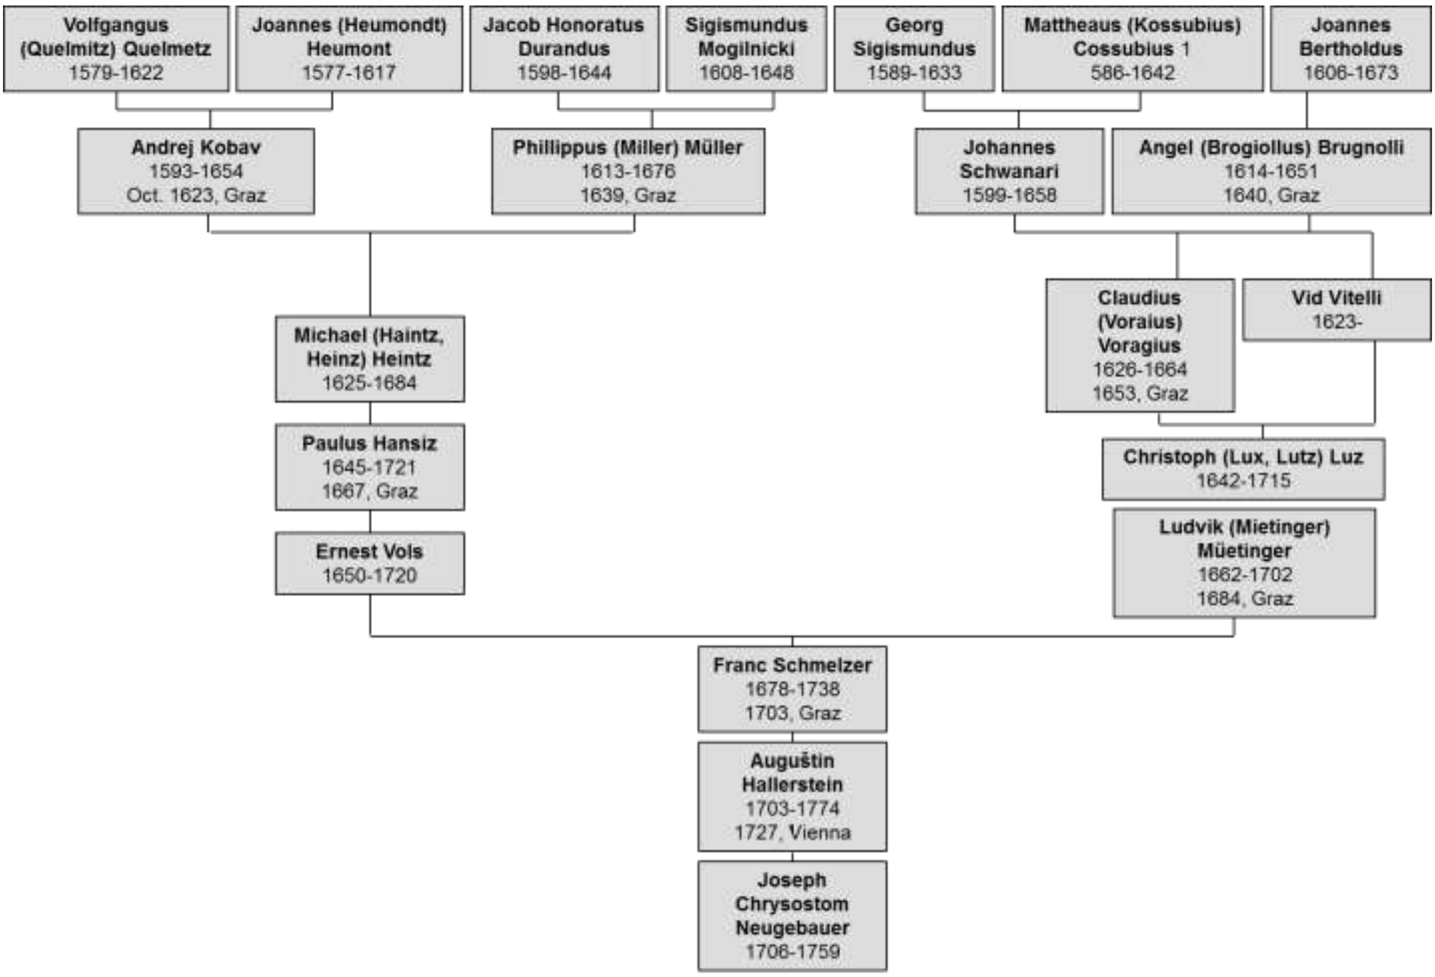

Figure 14-5: Five generations of the academic ancestors of the Carniolan baron Hallerstein, who was among the most meritorious teachers of European vacuum experiments at the Chinese imperial court

painted the whole device,[1618] and at the same time its parts.[1619] Hallerstein's friends among the Viennese Jesuits were not invited to experiments except the Jesuit numismatist and mathematician Josef Khell von Khellburg with whom Ingenhousz corresponded on June 20, 1772.[1620] Hallerstein nevertheless learned about Ingenhousz's successes through his Viennese comrades who gathered around the editor of Hallerstein's works, the Slovak Jesuit Maximilian Hell. Thus, Hallerstein knew all about the puzzles of vacuum at a time when his colleagues, the French Jesuits, presented a vacuum pump to the Chinese Emperor on March 10, 1773.

14.5.3 Rangaku 伊學), Erekiteru (エレキ, エレキテル), and Vacuum Pumps in Japan

The transfer of Western books which discussed vacuum to Japan began with the Jesuits, who, after being expelled from Japan, transferred their main precious books across the sea to China. These books still have their Japanese proprietary inscriptions, but they should not be confused with the ownership entries of the Chinese Jesuits with Hallerstein included, who still retained their official titles of the Japanese provincials and visitors, although their journey to Japan had been already banned for some time.

Among the most important Japanese libraries were the books collected by the family of owners of copper mines Sumitomo. The beginnings of their book collection probably go back to the time of the beginner of the family upswing Masatomo Sumitomo (住友 政 友, * 1585 Fakui north of Kyoto; † 1652), who designed his shop of medicines and books in Kyoto in 1630. Last but not completely least, the books were purchased by his adopted son Tomomochi Sumitomo (Riemon, * 1607; † 1662), who studied mining in Deshima to help with copper mining in the company of his father Riemon Soga (* 1572; † 1636). Riemon founded the company Izumiya in 1590; he successfully married Masamoto's older sister and learned Western procedures for obtaining copper and silver from minerals.[1621] In 1904, Kichizaemon VI Sumitomo Tomoito (住友吉 左衛 門, * 1865; † 1926), the fifteenth heir of the Sumitomo family, founded the library in his hometown Osaka, and two decades later, he donated to it his own valuable collection including his hundred and fifty rare old books. The library is now named Nakanoshima in the Prefecture of Osaka.

It's not clear when Sumitomo family acquired individual items among the books in the spreadsheet, probably they got them more as antiquarian curiosities in early 20th century. However, it is assumed that the electric Erekiteru in experiments and the vacuum techniques described in them soon became well-known to the curious Japanese. Sumitomo family did not purchase early vacuum studies of Huygens, Guericke, Boyle, Pascal, Kircher or Schott, as only got Huygens's later collections (1905).[1622] Of course, Sumitomo’s family bought much less Jesuit works compared to Hallerstein's Beijing missionaries; however, Sumitomo had Bošković's *De micrometri* Objectives published in Karl Scherffer's Viennese Latin translation of optics by Nicolas Louis de Lacaille (* 1713 Rumigny; † 1762 Paris) from 1757/1758 and Benvenuti's *Optica* published according to Bošković's order in one of the later Viennese editions.[1623] Sumitomo's library did not have many Dutch rangaku works which were considered obsolete in Japan of the late 19th century, although the Leyden editions prevailed, including books of Borelli and Musschenbroek.

Sumitomo family did not acquire Agricola's works on the foundations of mining, and had only a few mining papers published before the Hallerstein’s death. Of course, they read the work of the beginner of modern mining using vacuum techniques, the Bolivian Alvaro Alonso Barba (* 1569 Lepe in southwest Spain; † 1662 Potosi in then Spanish Peru, now part of Bolivia), who earned his bread as a parish priest in Tarabuco and St. Bernards within the mining area of Colombia. Barba discovered amalgamation as a process of heating the gold, silver and copper ore in saline solution of mercury. He cooked in his copper vessels until he cleaned out enough pure metal. Barba's first Spanish edition was published in 1640, and the jealous Spaniards hid it

harshly, which does not mean that the early Sumitomo did not learn the basic features of Barba's discoveries. The other Spanish edition of 1729 was enthusiastically translated; Nicolas Lenglet Dufresnoy (* 1674; † 1755) translated it to the French language in 1751 under his penname Gosford. The Dutch edition appeared in 1740, while the Viennese Freemason Trattner published Matthias Godar's translation in 1749 and 1755. Barba considered salt mines,[1626] and the formation of rocks,[1627] especially these precious ones;[1628]

then he began his main goal, the metallurgy.[1629] Of course, his metals were connected to the planets;[1630] he painted his blast-furnace.[1631] He discussed the sympathies and repulsion between individual metals[1632] cast into special containers[1633]

through the roofs of the blast furnaces.[1634] He was also interested in the healing power of metals,[1635] and he used special vessels for the precious metals of platinum and gold.[1636] He published tables on the rudimentary properties of ores in Peru,[1637] which was, of course, an additional reason why the Spaniards jealously hided first issues of Barba's books. In the second edition, the Spanish editor included the treatment of the mines of Alonso Carrillo y Lasos (* 1582–?; † 1628 Córdoba),[1638] which added data on the Spanish domestic mines in the Pyrenees[1639] and the surroundings already in the Roman times.[1640] Barba used Paracelsus'[1641] and Galileo's work on Jupiter's satellites as possible new planets. Of course, Galileo's assumptions undermined the ancient scheme of the number of planets in relation to the number of metals.[1642] Juan de Andosilla of Colegio Imperial

de Madrid examined Barba's discoveries,[1643] followed by the Spanish royal cosmographer Christian Rieger (* 1714 Vienna; † 1780 Vienna) in 1763;[1644] Rieger later became rector of the Jesuitcollege in Ljubljana where his knowhow of minerals through Zois's domestic teacher Gabriel Gruber influenced the domestic headquarters of Baron Žiga Zois, the owner of the mining plants in the Jesenice and Bohinj. Nevertheless, Barba's amalgamation process, invented in 1609, drowned in oblivion, and the Freemason Ignaz von Born again resurfaced it in Slovakia, Prague and Vienna.[1645]

14.5.4 Erekiteru

We offer the first descriptions of the introduction of vacuum pumps and electrostatic generators among the Japanese; devices were largely a product of the Dutch knowledge of vacuum researchers including Christiaan Huygens and Pieter Musschenbroek. In this way, they were hourly available among Japanese translators from Dutch language called Rangaku as part of Western science Yogaku (洋 學).[1646] In view of the Japanese connection with the Dutch, we can expect that the Japanese easily learned about the vacuum experiments of the Dutchman Huygens (* 1629; † 1695), who began with his research of vacuum in The Hague in November 1661 after returning from a visit to Boyle. Huygens concluded his experiments with an unpleasant dangerous explosion during his lecture in Paris on April 14, 1668. Leyden's professor of philosophy and founder of the cabinet of physics in January 1675,[1647] Burchard de Volder (* 1643 Amsterdam; † 1709), continued to work as the executor of Huygens's last will. Franciscus Sylvius Le Boë's Leyden student Volder collaborated with Pieter's father Jonathan Musschenbroek (* 1660; † 1707), and Pieter's uncle Samuel Musschenbroek, who manufactured vacuum pumps in their workshop opposite the University. They used the designs of Boerhaave's professor of Aristotelian Philosophy Wolfers Senguerd (Wolfgang Senkward, Senguerolus, * 1646; † 1724) and Volder. Volder gave them Boyle's plans acquired in London in 1675, so that soon enough, all experimentalists among Leyden teachers were provided with vacuum pumps, telescopes, microscopes and surgical devices.[1648] Senguerd provided private lectures with experiments at his home. In 1680 he described his own vacuum pump with one e piston in his Philosophia Naturalis;[1649] he used the achievements of Hooke, Papin and Boyle. 'sGravesande replaced the late Senguerd in 1724, and he also invited the students mainly to his home-based cabinet of physics, which was better equipped than an outdated physical laboratory at the university.[1650] After studying with Senguerd and Volder, 'sGravesande took up a botanical department at the Faculty of Medicine in 1709, and nine years later he was also offered a chemistry department at the Faculty of Philosophy. There he immediately put a vacuum pump into a chemical laboratory, designed experiments with it and began to cooperate with an Amsterdam-based scientific instrument maker Daniel Gabriel Fahrenheit. They competed with physicists who were in those times called "experimental philosophers."[1651] Senguerd's and Boerhaave's student Pieter van Musschenbroek took the Chair of Physics at Leyden University in 1739, and a full-decade later, the first cousin of Hallerstein's mother Baron Erberg published the Latin translation of P. Musschenbroek's magnetic experiments in Ljubljana. Even though Sumitomo's library did not have Boerhaave's works, Boerhaave's uses of electrostatic and vacuum techniques for his chemistry and medicine were the first-class Dutch exports items for curious Japanese.[1652] The Dutch doctors from Deshima soon learned all details of Pieter Musschenbroek's vacuum techniques and Leyden jars described by the Dutchman Musschenbroek in November 1745. Of course, Sumitomo bought P. Musschenbroek's books in Latin and French editions from 1748 and 1751.[1653] Hallerstein used the same books, although not always in the same editions; he read them in Ljubljana, and later in his Beijing Library. Sumitomo also enjoyed the highly popular Physics of Cartesian Jacques Rohault (* 1620; † 1675) in Samuel Clarke's edition issued in 1718. Of course, this edition completely lost the Cartesian spirit of

the first edition of 1671, as Clarke added abundant Newton's remarks as footnotes bellow the lines, especially regarding to Boyle and Huygens' vacuum experiments. Those notes below the lines became much longer than the original Rohault's texts.[1654] Hallerstein's Pekingese Jesuits did not go so far and preferred the Geneva Latin translation of Th. Bonet from 1674 and the French Parisian reprint of 1683,[1655] which preserved the original Cartesian spirit. Rohault did not offer many illustrations of vacuum experiments, while he drew many optical and electrical examinations instead.[1656] Among the researches of mechanics published in the times of early vacuum experiments, Sumitomo's library much later acquired Monte, Borelli and Varignon's works. The books of Galileo's friend Guido Ubaldo del Monte also found its ways into the Auersperg and Valvasor's libraries of Carniola. Ubaldo described simple mechanical principles and gradually explained their use with nicely sketched machines.[1657] Borelli's posthumous edition came on daylight in Leyden and could therefore be part of the postponed rangaku export to the Japan Sumitomo Library with its nice paintings. The Japanese loved it despite the Latin language used, which many Japanese could not read; they were mainly observing the painting images, which was not uncommon in the land of the rising Sun. Galileo's student Borelli taught at one time Galileo's Chair of Mathematics in Pisa. Jointly with the Roman mathematician Michelangelo Ricci (1619; † 1682) he wrote about the forces involved in the collisions. That later cardinal Ricci was a recipient of the famous Torricelli's letter about a vacuum in his newly discovered barometer which began the whole story of the development of vacuum techniques that is still in progress. With Galileo and Torricelli's ideas Borelli clarified the hydraulic movement in caves, siphons and pipes.[1658] Borelli drew capillary phenomena and explained the vacuum phenomena in Torricelli's barometer;[1659] he explained Roberval's experiments with a barometer connected in a vacuumed vessel designed in 1648[1660] and Mersenne's weighting of air.[1661] He used the presumption of the smallest particles of air[1662] but preferred to remain within the barometric vacuum experiments of Florence academics without using vacuum pumps. Similarly, in the conclusion of his book, Varignon described the puzzles of vacuum in an open tube filled with fluid unilaterally pressed with a finger of a brave experimenter[1663] as he was not yet aware of the harmfulness of the Idrija mercury.

Sumitomo acquired the first two of the three volumes of Viennese physics of the Piarist Dalham[1664] and Scarella's Bolognese discussion of magnets.[1665] Both books were less popular and perhaps nearly unknown in Beijing of Hallerstein's days. On the other hand, Sumitomo's library had an important Priestley's history of electricity in the German edition of 1769,[1666] Cavallo's experiments with electricity in a slightly later also German edition of 1782,[1667] Volta's Letters on Flammable Marsh Gases (1778),[1668] Nollet's electrical research in the French and Italian editions (1754, 1755).[1669] Florian Dalham de St. Theresa (* 1713 Vienna; † 1795 Salzburg) was a monk of the order of the Piarists, who at that time replaced the Jesuits at professorial positions in Central Europe including Habsburgian monarchy. Dalham courageously used the atomistic approach to prove the existence of a vacuum[1670] by giving the reader a sketch of Guericke's experiment with hemispheres[1671] and the Torricellian barometer.[1672] He also used Boyle's pump, but preferred the Dutch version of Musschenbroek and 'sGravesande double-barrelled design with two pistons;[1673] he used them for many experiments[1674] all the way to Papin's pot at high pressure.[1675] Finally, he afforded some data about the electricity[1676] and explained William Watson's (1715 London-1787 London) measurements of speed from 1748[1677] and Bose's discussion of

electric light.[1678] In doing so, he used a friction electric spindle without a Leyden jar, which was required for the perfect *erikateru*. As it was usual for Piarists and other opponents of Jesuits, Dalham preferred Newton's model of gravity[1679] than the more difficult and complex Bošković’s ideas. Luckily, Dalham still swore on the French version of the blades of the ship propelled by the power of a pair of horses[1680] instead of the later steam turbine experiments. He dedicated a special chapter to the puzzles of vacuum needed for the gunning of ballistic missiles.[1681]

The Netherlands-Japanese or Netherlands-Viennese-Ljubljana transmission of Dutch electrostatic and vacuum techniques were faster than the Chinese Jesuits whose resources were brought by the Jesuits from Paris and Lisbon to the Beijing French and Hallerstein Portuguese missions. The same applies to Erekiteru's electrostatic generators (エレキ, エレキテル), which were quickly beloved by the Japanese during the era of chamberlain (sobashū) Tanomi Okutsugu (田沼意次, * 1719; † 1788), who became senior counselor (Rōjū) in 1769.[1682] With his interventions he marked the era between 1760 and 1786. The Erekiterus are very popular among the modern Japanese children and web is full of them. In 1765, the botanist Gotō Rishun (後藤梨春, * 1696; † 1771) described the *erekiteru* in his book Orandabanashi (紅毛 談, Kōmōdan, The Tales of the Netherlands), and in 1768 and 1771 the Dutchmen introduced to shogun an enhanced Guericke's rotating electrostatic generator of John Dollond's son-in-law Jesse Ramsden (* 6/10/1735 Halifax; † 5/11/1800 Brighton). Ramsden developed the device after Hauksbee's replacement of the Guericke’s sulfide ball[1683] with glass ball. He put it on sale in London in 1766, so the glass-disk version ribbed with four brushes quickly reached the networks of the Japanese Shogun in Edo, today's Tokyo.

Gennai’s student was the expert on Rangaku Morishima Chūryō (Katsurgawa Hosai, courtesy name Shinra Bansō or Nisei Fūrai Sanjin in the meaning of the second Fūtai Sanjin, 森島中良, * 1754; † 1810?). In 1787 in his Dutch diversities (Kōmō zatsuwa, 紅毛 雑 話), Morishima Chūryō offered a detailed explanation of the composition and functioning of the electrostatic machine, although Morishima Chūryō was primarily a writer of popular fiction. In 1798 in Naniwa (Osaka), Akisato Ritō (秋里籬島, worked 1780-1814) and Takehara Shunchōsai (竹原春朝斉, † 1800) in his fantastic narrative Settsū meisho zue (折津名所圖繪, Famous places in the Settsu province) published by Kawachiya Tasuke (浪花, 河内屋大助), described Hikida’s store in the Fushima section of Osaka, where the trader exhibited an *erekiteru* designed by the artist Ōe among his Chinese and Korean offerings. They painted another guest who wrote his notes with the

In 1776 **Hiraga Gennai** (平賀源内, nicknamed Fūrai Sanjin, 風来山人, * 1728/29; † 1779) successfully assembled an electrostatic device with the Leyden jar in a wooden box about two decades after Hallerstein and Benjamin Franklin got their electrostatic machines from London. Gennai's precious machine so profoundly marked the Japanese that even today the modern Japanese are cheerfully driving it under Gennai's name, looking forward to its sparking in the air or vacuum. In the 1760s, Gennai helped to exploit the Chichibu mine west of the city Chichibu in the Prefecture of Saitama (埼玉県, Saitama-ken), and then assisted in the development of the coal mine Akita in the same prefecture in 1773/1774. He thus connected with the mining techniques of the family company Sumitomo, but he was particularly aware of the troublesome vacuum pumping of underground mining waters that were best handled by the European inventions of steam engines. Gennai contacted the Dutch and the Japanese interpreters of Dutchlanguage in 1764, by borrowing important books from Johnston's inventory of animals, Dodonaeus’ herbarium, or George Eberhard Rumphius’ (* 1627; † 1702 Ambon) book on fossils from Indonesia D'Amboinsche Rariteitkamer published in Amsterdam by F. Halmi in 1705. The inventor Gennai, in many respects, embodies the modern sparkling Japanese spirit, while the fine television shows were recorded about his actions.

Western script.[1684] At that time, the private trade of skippers and crews of Dutch ships visiting Nagasaki brought numerous books to Japan. Those prints described geography, medicine, pharmacy,[1685] as well as vacuum techniques. Yoshio Kōzaemon studied Dutch books and asked Dutch doctors about their procedures, so through his translations he became a recognized expert in astronomy, geography and botany. He was appointed interpreter in 1742, and then got that nice duty a dozen times more.[1686]

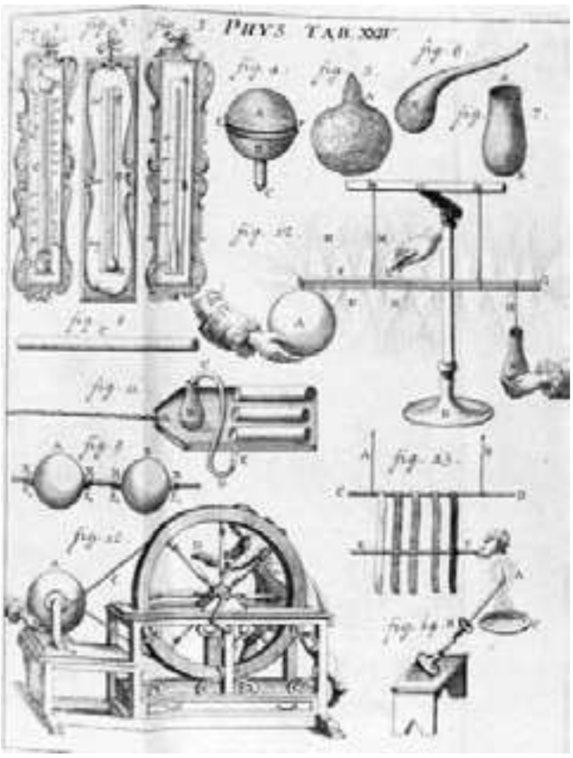

Figure 14-12: Erekiteru in Dalham Physics from the Sumitomo's Library (Dalham, 1753, pics 10-12 on table 24).

In 1788 Hashimoto Sōkichi (橋本 宗 吉, * 1763 Osaka; † 1836) began studying with Ōtsuki Genryō. He founded his private academy Shikandō in 1801.[1687] There Hashimoto later taught, cured and published the famous book Static electricity generated in the Netherlands (1811) under the protection of Hazama Shigomi (間 重, * 1756; † 1816) from the Astronomical Office and the Tenmongata Observatory (天文 方). Hazama Shigetomi was an important financier and former student of astronomer-physician Asada Gōryū (麻田 剛立, 1734-1799) in Osaka merchant academy *Kaitokudō* (懐徳堂). Their studies of physics called the investigation of basic things (*kyūrigaku*, 窮 理学) followed the example of Neo-Confucian China. They added their first steps in chemistry called seimigaku (舎 密 学) by the misspelled term from the Dutch word for chemistry "*Scheikunde*".[1688] In 1811, Hashimoto Muneyoshi published the first Japanese electrical manual under the title Foundations of Erekiteru as the Dutch know it (Orhan Shisei Erekiteru Kyūri-Gen). Hoashi Banri (帆 足 萬里, * 1778; † 1852) wrote about the Laws of Nature (窮 理 通, Kyūri-Tsū) in 1810, using as many as thirteen Dutch books. The Japanese researchers of electrostatics and vacuum techniques have called their electrostatic generator an "erekiteru" (today also denki, fuka) as part of physics (today: butsuri, butsurigaku), or physical sciences (today called "rigaku"), or natural sciences with physiology called "kyūrigaku", or chemistry called "semigaku" (today: chemisutori, chemisutori, kagaku). The Japanese borrowed European (Dutch) names for barometer and chemistry, but not for watches or physics.

Hashimoto Sokichi supported the ideas of Benjamin Franklin and developed the erekiteru in the busy city of Osaka in 1811,[1689] where, under the influence of Sumitomo, every sixth of the 300,000 inhabitants dealt with copper reselling in 1685.[1690] Nearly two-thirds of the annual production of 6,000 tons of Sumitomo's copper was exported to China in 1697 for the manufacturing of coins.[1691] Of course, the entrepreneur Sumitomo did not avoid even the direct exchange of goods, and he also acquired a lot of Chinese books or the books of Chinese Jesuits, although such reading was officially not allowed before 1720. Of course, the prohibition of ordinary folks does not apply to the wealthy.

In any case, Osaka became the center of modern Japanese electric and vacuum experiments, so Sokichi built his electric device in 1813 under the name of Static Electricity (Erekiteru yakusetsu). In doing so, he mainly relied on Dutch sources in connection with Musschenbroek's Leyden jar

before the Japanese in the mid-19th century found out that the Dutchmen were, nevertheless, not the leading European scientists compared to the English, the French, or the Germans. The French revolutionaries temporarily occupied the Netherlands which convinced the Japanese that the Dutchmen might not be so powerful as they imagined. Tachu Horiguchi undertook static electricity a little later in 1814.[1692] Sakuma Shōzan (佐 久 間 象山, Zōzan, * 1811 Shinshu; † 1864) used Japanese domestic *erekiteru* for electric shocks with the induction flow of 1860,[1693] like Ingenhousz and Franklin imagined in their time.

The Japanese fell in love with vacuum pumps a bit after they endorsed erekiteru, although they had previously looked at their paintings in Winkler's or Martin's books, while Keill did not publish any proper pictures. Philipp Franz Balthazar von Siebold (* 1796 Wurzburg; † 1866 Munich) brought some vacuum pumps and a galvanic device in 1823, and the first Japanese vacuum pump was assembled at New Year's Eve in 1820. Siebold tried to smuggle the map of Japan and other secrets;[1694] the values of Dutch translations called rangaku were diminished when Siebold was arrested. He had to sail out of Nagasaki just before the new year of 1829 and returned only after the attack of Commodore Perry in 1853.[1695] Hasashige Tanaka (田中 久 重, * 1799 Kurume; † 1881) put together a flying machine and a pump for his air rifle and munjitō as "eternal light" in the forerunner of a company which his son-on-law later developed. That company got its name Toshiba officially designated only in 1978.[1696]

The Japanese have published their own description of the vacuum pump barely in the book of Rinsō Aochi (青 地 林宗, * 1775; † 1833) called Atmospheric Observations (気 海 観 ī, Kikai Kanran), and soon after that in 1834, in nine volumes of Udagawa Shinsai (宇田 川 榛 齋, * 1769; † 1832), who proved the use of air for breathing or burning and calculated the density of air. Udagawa Shinsai collaborated with Ogata Kōan (* 1810; † 1863) and Shinsai Udagawa's son-in-law Udagawa Yōan (宇田 川 榕 菴, * 1798; † 1846), who succeeded him in assembling the first Japanese Voltaic battery in 1831. He published The initial principles of chemistry (舎 密 開 宗, Seimi Kaisō) in 1840, based on William Henry's Elements of Experimental Chemistry (1799) with the Dutch adaptations of the Lavoisier system.[1697]

Motoki Ryōi (本木庄太夫良意, 1624–1697) translated the Dutch edition of Johann Remmelin's (* 1583 Ulm; † 1632 Augsburg) Pinax mocrocosmographicus (1667, Amsterdam: Paul Mathias)[1698] and thus paved the way of his heir Motoki Ryōei (Yoshinaga, 本木 良永, 1735–1794), who was already the third generation of the same family of interpreters Motoki. He translated the Dutch botanic in 1771 following the order of Hiraga Gennai. Then Motoki Ryōei translated astronomy (1773/74-1788), and in 1792 a further clarification of the barometer (Oranda kōshōgi fukai) which was strongly vacuum-based. The student of Tadao Shizuki[1699] named Baba Sajurō (Sadayoshi, 馬 場 佐 十郎, * 1787; † 1822 Edo) was the leading Dutch language teacher and official of the Astronomical Department's bansho wage goyō. In 1810, the Motoki's book was expanded into a Translated Handbook for the Barometer (Senkitō yakusetsu), also called Barometoru tenki keigi. In 1817, Baba published Taisei jiki zusetsu as Illustrated explanations of the Western clock and Garasu seihōshūsetsu (Complete explanation of glass manufacturing processes).[1700]

On the other shore of Yellow sea Hallerstein read the books of the Dutch vacuum researcher Huygens, mostly the Horologium oscillatorum in the first Paris edition of 1673; his neighbors at the French Jesuit station afforded a former copy of the Lyon Jesuit college.[1701] Despite direct connections with Dutch vacuumists, Motoki Ryōei preferred to translate the book by Johann Adams senior (* 1709; † 1773 London), the maker of vacuum mathematical devices at the court of King George III (1738-1820). Of course, Motoki Ryōei used the Dutch version because he did not know English

language. Although Motoki Ryōei did not add newly invented ideas, he also commented the works of Benjamin Martin (* 1704 Worplesdon; † 1782 London) and Johann Heinrich Winkler (Winckler, * 1703 Wingendorf near Lauban; † 1770 Leipzig). Winkler's Electricity (1744/45) influenced the Stična Cistercians. Winkler's Anfangsgründe der Physik (1754) was used by Motoki Ryōei in the Dutch translation (1768). It was also purchased by the cousin of Hallerstein's mother Erberg for higher studies in Ljubljana in 1755. Winkler was Christian Wolff's fan and he took over Wolff's Department of Philosophy at the University of Leipzig in 1739. Unfortunately, he did not afford any index in his physics textbook. After the introductory mathematical part, he described the Torricellian Barometer in the variations of Rohault, Wolff, Musschenbroek and the like,[1702] but did not deal with Guericke's vacuum experiments, which Winkler preferred to describe in his book on Electricity six years later.[1703] Winkler described Musschenbroek's experiments with a mercury thermometer.[1704] Motoki Ryoei used Benjamin Martin's part Philosophical Grammar (1735) designed for the teens in the Dutch translation of the later famous historian Jan Wagenaar (* 1709; † 1773) addressed as the Filosofische Onderwijzer (1744 Amsterdam), which Hallerstein's uncle Erberg read in the Italian translation of 1769.

Žiga Zois had the other Benjamin Martin's works on a vacuum pump, on a steam engine and optics. After the introductory part,[1705] Martin mostly excelled in final fourth part of his work entitled Of Hypotheses, of Experiments, of various Instruments for that purpose their Use.[1706] There he described the vacuum pumps, but only in later editions he added Hauksbee's achievements with the image of Hauksbee's pneumatic device, namely the vacuum pump.[1707] In Japan, the edition of 1735 did not have the first three paintings from the reprint published in 1755.[1708] Martin explained the philosophical background of vacuum and electricity[1709] in the introduction, but did not publish the image of erekiteru because he saved the treatment of static electricity for his other books. In all editions of his Philosophical Grammar book, Martin divided his dialogues between student A and teacher B in the in four parts, where Aerology[1710] figured as a third part with the Theory of the Atmosphere or the Air in the first four chapters.[1711] Both Martin's speakers admired Boyle's vacuum pump[1712] in Roberval's Parisian performance under Pascal's influence.[1713] Martin added Keill's calculations,[1714] the latest 'sGravesande's and other experiments.[1715] In the first edition, which was used by Motoki Ryoei, there were no images of a double-piston pump[1716] or long footnotes below the line, which even exceeded the length of the original text in the fifth edition of 1755. The pages dedicated to the vacuum were those where Martin most notably added footnotes and additional sketches after the first edition, which clearly shows how rapidly vacuum technology developed during Hallerstein's youth.

Shizuki Tadao (志 筑 忠雄, Chūhirō Nakano, Ryūho, * 1760 Nagasaki; † 1806) due to physical weakness soon retired as a rangaku interpreter in Nagasaki.[1717] He relied on Chinese sources in his Copernican theory from 1759 and 1766, and between 1782-1802 he translated a somewhat outdated book of John Keill (* 1671 Edinburgh; † 1721 Oxford). In 1798, he first published the second part of Keill's Introductiones ad veram Astronomiam as the New Text of Transient (Calendar) phenomena (Rekishō Shinsho, 暦 象 新 書) and communicated the following two parts on physics and circular motion in 1800 and 1802,[1718] although the physical part was the first in the original Keil's design.

Perhaps the poor translator Shizuki Tadao had a bit more trouble with that part. The first two volumes were first written in classical Chinese language, but in the end, all three volumes were published in Japanese language.[1719] During his studies at

Motoki Ryoei's class, Shizuki Tadao quickly found out that he could choose the more modern records of Benjamin Martin or Winkler instead of Keill's data[1720] for his translation. Keill illustrated hydraulic vessels,[1721] experiments with ships,[1722] slopes of cannon shots;[1723] but he did not afford to present any vacuum pumps or electrostatic experiments. He finished the physical part of his work with the centrifugal power of the virtuous Huygens,[1724] whom the translator Shizuki Tadao probably also knew from other Dutch sources. In the Milan edition of 1742, Keill's work was extremely popular among the Ljubljana and Novo Mesto Franciscans; Žiga Zois used the Parisian edition of 1746. Hallerstein himself, however, preferred the 'sGravesande's Leyden Edition published in 1725.[1725]

14.5.5 Conclusion

Hallerstein's role in Beijing's electrical and vacuum experiments is not as clear as his publications in astronomy, cartography or Chinese demographics. Many of these studies were designed as joint works under the auspices of the imperial court of Qing dynasty.[1726] Since the Carniolan Hallerstein was a leading Jesuit scientist in Beijing, none of the electrical or vacuum investigations could have been carried out without his participations. Here we first presented the Beijing-based Jesuit Electrophorus as the fundament of the later Voltaic inventions, which are the foundation of modern vacuum science and electrical engineering. Carniolan Jesuit Hallerstein was undoubtedly a blessing for Chinese science and technology, but the Chinese lost their Jesuits shortly before the Opium Wars so that Hallerstein's knowledge could not help them in defense anymore. The beginnings of Hallerstein's vacuum and electrotechnical research were indeed bright and enabled later developments of dynamos and electric bulbs[1727] after the Jesuit technical heritage was destroyed at the Imperial Summer Palace.[1728]

The Chinese people liked to imagine cyclical historical developments, while the Japanese have always preferred a linear arrow of time. The Chinese and Japanese approaches to our western science were and still are basically different. While the Chinese would like to see that all the European knowledge has evolved from ancient Chinese inventions, the Japanese prefer the opposite extreme and try to sell themselves as mere emulators of Western or Chinese achievements. In fact, the Japanese have received so many Nobel Prizes in the last decade, but the Japanese tried to diminish their merits as some Japanese winners are exploring in the United States anyway. The reality, of course, is different. The overlapping Jesuit-Chinese merit of Hallerstein's days made possible Volta's discovery of the battery as the basis of electrodynamics, while the Japanese-Dutch rangaku association was also instrumental after the Dutch Musschenbroek's discovery of the Leyden jar and the improvements in the vacuum technique that enabled the Japanese erekiteru as a design unusual for European researchers. The electrophorus of Hallerstein's Jesuits may have been the latest Jesuitical achievement in Beijing. It has been upgraded by Europeans over time and returned to China in the form of a completed electrical engineering. In today's globalized world, something similar cannot be easily repeated. London's exports of Leyden jars to Franklin's Philadelphia also returned to Europe as boomerangs with lightning rods and other Franklin achievements, although we still do not know what kind of improvements of electrostatic and vacuum devices may have been designed in the then Ljubljana or in Edo (Tokyo) except for erekiteru. In any case, the needy Needham believed that the Japanese and the Chinese would develop similar Westernized science even without European intervention, but we, together with Nakayama, endorsed the opposite view.[1729] There are many different possibilities of economies, cultures, languages and all other human endeavors, therefore the humans could also develop different kinds of sciences if they have a chance to avoid the globalization and uniform approach towards the seemingly unique truths.

The readings define the modern man. The attractive weighty wisdom determined the approaches of Hallerstein more than anyone else, as accomplished more than all other scientists of

his generations. He achieved no less than the position of the leading scholar of the heavenly empire. Hallerstein's role in Beijing's electricity exploration is by no means as clear as his leading role in the Chinese astronomy, cartography or demographics. His many research projects were often a social project under the auspices of the Chinese imperial Qing Dynasty.[1730] In this study, for the first time in depth, we presented his share of the invention of the electrophorus, which was the foundation of Volta's later successes. Above all, we presented the bookshelf from which Hallerstein pumped up his enviable knowledge.

In any case, Hallerstein was Slovenian language speaker and worth of the all money available. A Chinese national disaster in the 19th century might have rotated differently if anyone could continue Hallerstein's transfer of knowledge from Europe to the Chinese court (and back). But there was no such hero around, and the shame of defeat in the Opium Wars (1839-1841) was the reflection of the deep technical backlog of the Chinese in decades after Hallerstein's death. On the other hand, the creative transmitters of knowhow of Hallerstein's sort made the world a global unit and prevented any possible successful development of other non-European types of sciences and technology at the Far East.[1731] The world became one, but we could hardly judge if it became the best of all possible worlds in Leibniz's sense.

15 Pumping Vacuum for Full Enlightenment

15.1 Vacuum Pumps as Standard Experimental Tools for Enlightenment

It is hard to decide if we the Westerners borrowed more for the Far Easterners or vice versa, especially after the modern global success of the Chinese knowhow in the Anthropocene. In any case, the period of European enlightenment with Hallerstein at the top Beijing scientific positions was decisive for the technological modernizations of the world we still live in.

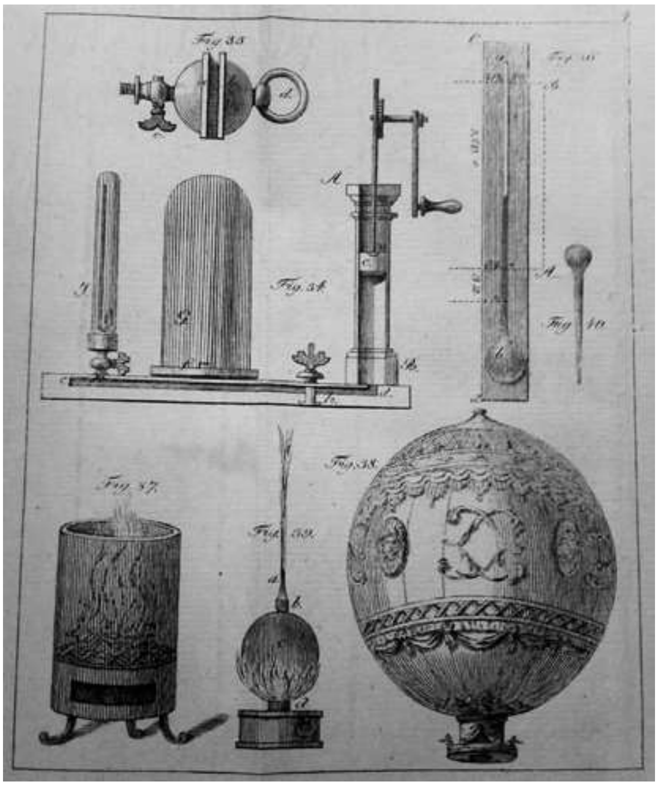

Figure 15-1: Vacuum pumps in the Ebert's book for youth held by the Ljubljana Franciscans' library (Ebert, 1804, table 5, with the permission of Prof. Dr. Miran Špelič, OFM).

The enlightenment technological modernizations were based on British steam engines which reversed the techniques of vacuum pumps to achieve higher instead of lower pressures. Hallerstein and his collaborators presented the heavy vacuum pumps to the Chinese emperor, but they failed to do the came with even heavier Savary and Thomas Newcomen's pre-Watt steam engines also because those machines were rare in Hallerstein's native Europe. The failure of Hallerstein's Jesuitical transfer of steamboats knowhow to Beijing might be decisive for later Chinese humiliated defeats in Opium wars, because the Chinese effectively missed few decades of westernized modernizations of the techniques including vacuum pumps and steam engines accelerated during the Napoleonic wars.

15.2 Enlightenment Vacuum Pumps among Slovenes

The export of vacuum devices to the Far East was just one aspect of globalization of sciences expanded across the oceans. The similar spread simultaneously carried exported western novelties into the Russian or Habsburgian milieu of Peter the Great and the emperor Leopold I. Both passed their thrones to the able females like Katherine the Great and Maria Theresia, who finally succeeded in

Figure 15-2: Text and pictures in the Ebert's book for youth held by the Ljubljana Franciscans' library (Ebert, 1804, 61 and the table of paintings, with the permission of Prof. Dr. Miran Špelič, OFM).

modernization and westernization of their local sciences based on vacuum tools. Both empires and even the Chinese realm the Jesuits as their transmitters, but at least in Habsburgian monarchy the other monks were also instrumental in spreading the novelties, including Franciscans and Cistercians. As secularization and needs for state employed engineers grew, there were also many technical experts outside the monastic orders, especially in the Carniolan Idrija mercury mine.
The first cousin of Hallerstein's mother and once removed uncle of Jožef Kalasanc Erberg, a Jesuit

professor of mathematics and physics Bernard Ferdinand Erberg, brought to Ljubljana the first documented vacuum devices whose inventory is available to us. In a modern way he equipped the new Ljubljana higher education physics cabinet and filled it with his 54 new experimental devices in 1755, with which he emphasized the research of vacuum. The winning horses of the Jesuit vacuumists of that time were of course Lana’s balloons.

Johann Jakob Ebert (* 1737; † 1805) published many natural historical textbooks,[1732] read by Carniolan barons Erberg and their neighboring Franciscans. In 1768 Ebert became the domestic teacher of the children of Russian minister Teplov in Petersburg. From 1747, Grigory Nikolaevich Teplov (Григорий Николаевич Теплов, * 1717; † 1779) led the Petersburg Academy on behalf of its president, Kirill Grigoevich count Razumovsky (Разумовский, 1728-1803). The widowed Teplov married Razumovsky’s first cousin and brought Katarina to the Russian throne in 1761/1762. He argued with Lomonosov and provided the Russian translation of Christian Wolff’s works, which paved the way for later Gruber's influence on Petersburg academics. In 1769, Ebert became a professor of basic mathematics in Wittenberg, and he took over the mathematical chair there in 1784. This was already the time when the thinking of the vacuum was greatly influenced by Bošković's physics.

15.3 Bošković's Vacuum

15.3.1 Introduction

The movement in the vacuum was the toughest nut of Aristotle's physics, which prevailed in Europe and in the Arabic countries for almost exactly two millennia. Despite the convincing experiments of Torricelli, Guericke, Boyle and Pascal, even the thinkers of the highest level as Descartes or Leibniz were unable to save themselves from the tangled rows of movements in an empty space. Bošković was the first to succeed in the long-awaited explanation of the vacuum as a mixture of Jesuitical Aristotelian traditions, Newton's physics and Leibniz's nature which does not allow jumps. Bošković designed the vacuum as a home for a multitude of indivisible point centers of forces without dimensions, ancestors of modern atoms or even elementary particles. After his three or more visits to Ljubljana, Bošković's physics became the foundation of Ljubljana's lectures of physics, as well as the core of teaching in the whole of Europe for at least three generations, involving Bošković's Viennese friend Karl Scherffer, Scherffer's student Gabriel Gruber, Gruber's student Jurij Vega, Vega’s student – and so on down to J. Stefan’s student Boltzmann, who explicitly praised Bošković.

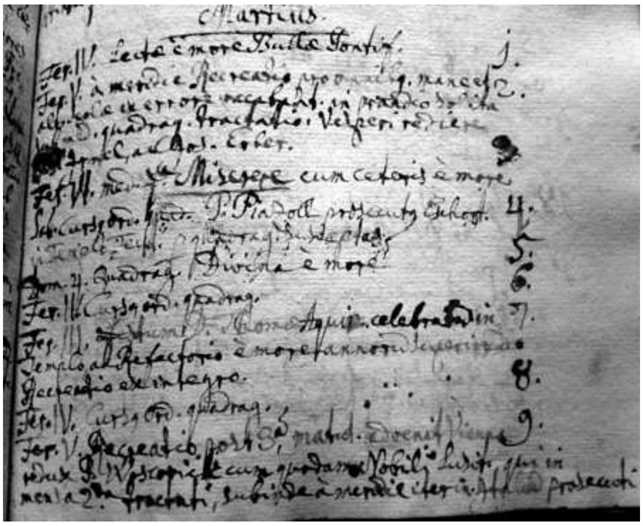

Figure 15-3: Bernard Ferdinand Erberg’s note in the Jesuitical diary of Bošković's overnight stay at the Jesuit of Ljubljana on March 9, 1758 (Erberg, 1758, 1742r)

Figure 15-4 Memorial plaque on Bošković's house in Dubrovnik (photographed by the author in 2012)

The theoretical solution to Aristotle's controversy has inflicted so many thinkers subjected to religious dogmas that they have not seen another

[1732] Wilde-1486, NUK-8405, Lind, 1992, 373 .

way out, except for the repugnant assumptions about an impossible vacuum, which, however, can be created by the Almighty God. Bošković saved them from this kind of problems, but at the same time the scope of his merits was also great at the experimental level. We will describe two of them related to the vacuum techniques of those days: measurement of the speed of light in an empty space or in the water to resolve the dispute between the defenders of the particle and wave nature of light, and the exploration of the vacuum in the solar system as the basis for a flight with a vacuum balloon.

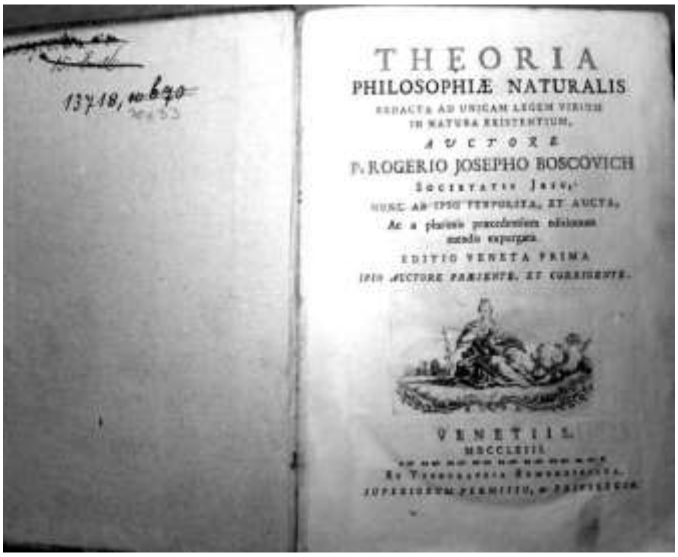

Figure 15-5: Venetian edition of the main Bošković's work (1763) at Ljubljana Franciscans' library (courtesy of Prof. Dr. Miran Špelič, OFM).

15.3.2 *Bošković's Water-Filled Telescope*

Newton was convinced that light consists of particles. Huygens and Euler preferred waves, while Descartes preferred a pressure between the light and the observer. Bošković admired Newton, although he occasionally doubted the scope of his gravitational law. To decipher the basic dispute of the then optics, as a teacher of mathematics in the Pavia and then at the Milan courthouse (palatine) school, Bošković suggested measuring with telescopes in 1768. In one occasion, he intended to fill the hose if a telescope with water, while Bošković's other suggestion was to observe the star through a vacuum or air. He described his ideas to his friend Lalande (1773),[1733] a Parisian freemasonic astronomer. Of course, Lalande immediately published Bošković's advice in a textbook printed in 1781.

Bošković assumed that he would observe the change in the angle of the aberration of a star by measurements through the telescope with an empty tube and with a tube full of water. James Bradley (* 1693; † 1762) first observed aberration in London as a small ellipse, described by the image of a vertically observed star during the Earth's elliptical journey around the Sun in 1725 and 1728. The ellipse is reflection of the Earth's own paths. The imaginary Bošković concluded that such an ellipse should increase when viewed through a telescope tube filled with water. The curious Jesuit knew that the speed of light waves decreased in water and thus increased aberrations. On the contrary to aberrations, the speed of particles of light would grow in water. Thus, he wanted to kill two birds with one stone: to confirm Copernicus's circulation of the Earth, and to decide on the controversy between the particles and the waves of light.

For the sake of disputes in Brera in Milan, Bošković could not arrange his experiment among the Italian virtuosi. He described it again in his collected works in 1785,[1734] just before his death. In 1788 and 1790, the British promoter of Bošković's ideas, the Scotman John Robison (* 1733, Boghall at Glasgow; † 30. 1. 1805, Edinburgh), found that Bošković's comparison between water and vacuum telescope would provide evidence of the absolute motion of the Earth; he expected failure, therefore nothing promising with the presumed same result for both telescopes. In 1782, the similar thoughts appeared to Robison's friend, a Glasgow practical astronomy assistant Patrick Wilson (* 1743; † 1811).[1735] Soon, their skepticism influenced Fresnel across the Channel in 1818. Bošković's device was barely tested by the director of Cambridge Observatory Georg Biddell Airy (* 1801; † 1892) on the star BY Draconis in March and in autumn of 1871.[1736] On his own merits, it was lucky that Bošković himself did not measure something like that because Robinson–prophesied perfectly correctly. The Airy did not measure any difference in the measurements through an empty and water-filled telescope, which would surely cause the impatient

[1733] Tomić, 2005, 263.

[1734] Tomić, 2005, 268.

[1735] Wilson, 1782, 58.

[1736] Airy, 1871–1872, 37.

Bošković to rage. Airy was already a special freak, because he ignored the newly discovered Neptune, and he disliked Faraday's ideas; the queen herself quit four times the propositions to bring angry Airy to the knighthood until she finally recognized his undeniable scientific merit in July 1872. Airy's many surprising measurements became one of the foundations of the physical world's reforms in Einstein's theory of relativity,[1737] which Airy no longer experienced as he died soon enough; he certainly would have disliked Einstein's ideas after he could not digest even Faraday's field theory.

15.3.3 Dubrovnik Natives on Lana Terzi's Vacuum Balloons

Bošković's vacuum telescope, of course, was not his only contribution to researching the vacuum. Bošković's Roman student and noble Dubrovnik cousin Brno Džamanjić (Bernardi Zamagna, Zamanja, * 1735, Dubrovnik; † 1820, Dubrovnik) initially became the Jesuit following Bošković's example but preferred to join the Dominicans after a ban on the Jesuit order. Like Benedikt Stay, Bošković and their cousin Rajmund Kunić (Cunich), their pupil Džamanjić liked to use his pen for Latin hexameters devoted to science. He heard a lot from Bošković about their religious co-brother Lana Terzi of Brescia, who had planned a flight with a vacuum balloon a century ago, without having enough money for such a feat. Džamanjić even more attuned to his heart Bošković's vision of the vacuum in space and the empty spaces which separate point centers of forces. Thus, Džamanjić published a Latin song about Lana's ship only a decade before the success of paper makers named Brothers Montgolfier.[1738] They were members of Lalande's Parisian Masonic Lodge of the Nine Sisters. The famous brother (not sisters) indeed ascended a similar but not completely empty device. Montgolfier's success, supported by the Freemasonry exclamations of Benjamin Franklin, if not the king himself and other Parisian observers, has greatly increased the popularity of Džamanjić' poems about two passengers on a flight around the globe, often reprinted by enthusiastic publishers of later generations. Dedalus's legend became flesh, even if until this day still without the vacuum of Lana Terzi.

Figure 15-9: Physics of the Lana in the list of Ljubljana Librarian Wilde in 1800 (Wilde, 1803, page 125, No. 1529)

Džamanjić conceived the flight of two courageous travelers, who surveyed the world on the Lana's vacuum ship. He first drew their adventures and then described them in two books, to which he finally added elegies on other topics. He mentioned Francesco Zanotti (* 1692; † 1777)[1739] as the secretary of the Bologna Institute, and brother of astronomer Eustachio Zanotti. With the maker of the vacuum balloon Lana Terzi, Džamanjić linked the verses to Johann Christoph Sturm of the Altdorf University, who supplemented the ideas of Lana Terzi in 1675.[1740] Džamanjić summarized the achievements of professor of mathematics in Pisa and Rome Borelli. Giovanni Alfonso Borelli (* 1608 Naples; † 1679 the school of Piarists in

Rome) used to be the disciple of Galileo's student Benedetto Castelli. Borelli was known as one of the leading researchers of flights. Borelli refused to imitate the birds because of the evidently weaker human muscles, and he also challenged the stability of the Lana's vessel under vacuum spheres. History has proved him right in both cases.

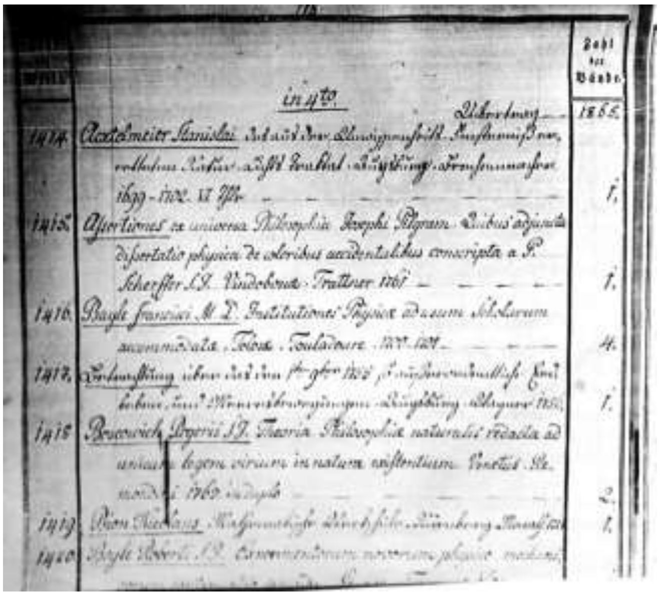

Figure 15-12: Bošković's book in the list of Ljubljana lyceum librarian Wilde in 1800 (Wilde, 1803, page 118).

Figure 15-13: Vacuum devices of the Carniolan agricultural society in the Ambschell's census of 1785 (Ambschell, 1785)

Džamanjić was interested in the opinions of Newton[1741] and Bošković about the composition of the Lunar atmosphere,[1742] as well as Bošković's model of the northern lights (Aurora borealis).[1743] He described Bošković's planned tour for the observations of Venus's passage over solar disc in California in 1769 with Kunić's song of praise; unfortunately, Bošković's trip has failed, since the Spanish owners of California forbade any visits of Jesuitical Bošković's religious co-brothers. Džamanjić continued the report on Bošković's disease in Istanbul,[1744] where Bošković again tried without a luck to experience the passage of Venus: as a monk he might have a lot of problem with goddess Venus anyway. Of course, Džamanjić refused an outdated fear of an empty, called horror vacui.[1745] He was assisted by the opinions of French monk Mersenne and Duns Scotus.[1746] As a real air-vacuum seaman, Džamanjić's passengers used Harrison's watch to accurately determine the position of their vacuumed vessel;[1747] they did not forget to take compass and maps with them, and they were particularly interested in the vertical distribution of clouds. It was a real problem there, as nobody knew for sure how the clouds interact with each other. Džamanjić has linked the story of his ballooning heroes under four vacuum balloons with fashion pioneering vaccination against smallpox after the poor bride of Emperor Joseph II passed away at the court of his mother Maria Theresa.[1748] Basically, Džamanjić referred to the English manufacturer of vacuum devices Benjamin Martin, Copernicus and the French thinker of the infinities of the worlds, Bernard le Bovier de Fontenelle (* 1657; † 1757).[1749]

15.3.4 Conclusion

The vacuum technique of Bošković's days was welcomed at the Jesuit physics lessons in the schools of Catholic countries, including those in the white city of Ljubljana. The operation of vacuum pumps was clearly effective, and Aristotle, Descartes, or Leibniz did not rightly question the durability of empty spaces, although the totally void spaces were still beyond any experimental reach. The facts did not fit in with the theory, and Hegel's "so much worse for the facts" was without chances because the brave Hegel was born only many years later. Bošković was the first to discover the Ljubljana and other Jesuit's best ways, according to which the vacuum can be

incorporated into Aristotle's doctrine using point centers of forces that led Bošković's heirs to a vacuum telescope and to a well-conceived vacuum balloon. While the first idea has been tested after a century as it has experienced its epilogue in Victorian Airy's England, the other is still waiting for new inventors of modern graphene-like materials that could successfully resist high pressure differences along the surface of the vacuum balloon. It may be waiting in vain, but nothing can be said for sure without a gypsy's divination, as the funny Italians say: if it is not true, it is at least well-founded (se non è vero è ben trovato).

15.4 Ljubljana Native's Vacuum Books in Brussels (On the 300th Anniversary of the Birth of Janez Karl Philip Kobencl)

15.4.1 Introduction

Among the many people of Ljubljana, who at various times and in various circumstances excelled themselves in Brussels, the greatest star was Bošković's most trusted best friend, Count Janez Karl Filip Kobencl. Janez Karl Filip Kobencl was born in the middle of July's heat three centuries ago in the recently built Ljubljana Kobencl's palace; at Novi trg 4 it is now used by the ZRC SAZU. His success will serve well for his descendants as an example of how a learned member of a small nation from a relatively small city should be established in the greater world. Kobencl, on the contrary of many of his Carniolan colleagues has proudly proclaimed himself as a Slovene, at least for the attractions of his student matriculations. Many scientists and researchers of vacuum technologies of their time, especially Ruđer Bošković and Janez Krstnik Paccassi, enjoyed the friendly support of the mighty Kobencl.

15.4.2 Kobencl and Coronini for Bošković

The Kobencl and Coronini families were closely linked. The nephew of the Brussels minister Count Janez Karl Filip Kobencl, the son of his older half-sister Kassandra Kobencl was the Gorizia native Rudolf Antonio Maria Coronini (* 1731, Gorizia; † 1781, Gorizia). Until 1752, he studied at the ten years previously established elite Viennese Theresianum. His professor of mathematics was Erasmus Frölich; after Frölich passed away, his prefecture of library was taken over by the physicist and vacuum researcher Joseph (Jacobus) Khell von Khellburg. Khell's books, full of sketches of vacuum experiments, were also extremely popular in Ljubljana. In 1756, Rudolf Coronini participated in geometric measurements to determine the boundary between the Habsburg Monarchy and Venice following Bošković's methods just before the first visits of Bošković in Gorizia and Ljubljana; Rudolf Coronini and colleagues compiled a map of Gorizia and Trieste, which was reprinted after Bošković's visits, in 1759. In 1772, a student from Gradišča (Gradisca d'Isonzo) Girolamo Pisanelli bound his examinations at higher Jesuit studies in Gorizia with a book of Rudolf Coronini which was first published in Vienna in 1769. Frölich's student of mathematics, the former Jesuit Johann Michael Denis, was assisted by the experienced Jesuit Andreas Friz (* 1711; † 1790, Gorizia) in his Latin poetry compiled for Coronini's Viennese edition. On 8 September 1780 Rudolf Coronini founded the Accademia degli Arcadi Romano-Sonziaci to become its member with the academic name Lebanio Crissanteo. The other distinguished academicians were Peter Anton Codelli as the ancestor of the later Ljubljana inventor of the vacuum elements of television, the former Jesuit students and Roman Arcadian member Giuseppe Coletti and the president of the academy Rudolf Coronini's uncle Guido Kobencl. Of course, the older uncle of Rudolf Coronini, Guido's brother Janez Karl Filip Kobenzl, kept Rudolf Coronini's works in his Brussels library.

Rudolf's sister Ludovica Coronini married Rudolf Strassoldo de Villanova; their brother, Ernesto Felice Coronini, taught philosophy with physics and modern vacuum techniques at Jesuit high schools in Gorizia. According to the legend, their ancestor Cipriano Coronini (Giovanni, (1500–1597) met Ignacio de Loyola in Rome, and he with his descendants helped Kobencl to settle the Jesuits in Gorizia and other places in 1615.

15.4.3 Technique of Guido Kobencl, Younger Brother of Brussels Minister Janez Karl Filip Kobencl

In 1747, Guido Kobencl moved from Ljubljana to Gorizia, where his older half-sisters Kassandra and Maria Elizabeth were richly married to the Counts Coronini and Edling. Guido, as the first president, helped to establish the Accademia degli Arcadi Romano-Sonziaci in 1780, which immediately became the official branch of the Roman Arkadians, founded a centuray earlier in honor of the Swedish Queen Kristina. The secretary of the Gorizia branch of the Academy was Giuseppe de Coletti (* 1744, Rome; † January 1815, Trieste) from the Florentine family, a former soldier and a printer. On 2 July 1784, Coletti began to issue Osservatore Triestino; he kept his editorship afloat throughout Napoleon's era until he calmed down forever. The brother of Gabriel Gruber's assistant the Jesuit Jožef Jakob Maffei was a Trieste patrician Karel Maffei. At the end of 1784, Karel Maffei became a member of the Trieste branch of the *Accademia degli Arcadi Triestini* under Coletti's leadership.

Guido Kobencl has widely contacted several scientists. In 1753 Bianchini wrote to him about the underground flow of the Karst river Timavo; in the meantime, he rightly emphasized the "Guido Kobencl's knowledge of the sciences of physics and mathematics".[1750] In a second letter to Guido Kobencl, Bianchini described the spring and underground flow of Timavo in Videm (Udine) on February 4, 1754. As early as in September 1602, the Devin Servite monk Pietro Imperati described Timavo as linked to the River Recca in a message sent to the Bolognese naturalist Ulisse Aldrovandi. Bianchini reported to Kobencl about the underground voids resembling vacuums; besides the caves around Timavo, he mentioned Nile and other famous rivers. At first, Bianchini felt that the river under the Kobencl's Predjama Castle was connected by the underground flow to Timavo; he carefully explored the karst caves to find an underground water connection with Cerknica Lake.

Figure 15-15: Guido(n) Kobencl (Guodobald Cobenzl, * 1716; † 1797), the younger brother of Janez Karl Filip Kobencl

Bianchini visited numerous caves in the Primorska region and finally found that only the river (Recca) flows underground into the river Timavo, which Gruber assumed after him.[1751] Gruber realized that the drinking water of Timavo gets a strange taste when it blends with the earth on its underground paths between the coast and the sea.[1752] He also sent the letter to Count Kobencl in Gorizia. Gruber thoroughly examined the water regime of the Planinsko polje and the entire Inner Carniola (Notranjska) region, since it was of fundamental importance for his Ljubljana canal; he personally examined Cerknica and on that occasion described the Idrija mine.[1753]

[1750] Bianchini, 1754 *Osservazioni*, pp. 81.

[1751] Tavagnutti, 2000 *Giovanni Fortunato Bianchini*; Gruber, *Briefe hydrographischen*, pp. 157.

[1752] Gruber, 1781 *Briefe hydrographischen*, pp. 157–158.

[1753] Gruber, 1781 *Briefe hydrographischen*, pp. 35; Korošec, 1967 *Beseda dve o Steinbergovem*, pp. 18.

On June 3, 1754, a friend of Gvido’s brother Janez Karl Filip, Ruđer Bošković, wrote to Bianchini about his ten-year exploration of the Rimini port. At the same time, Bošković sent to Bianchini his 75-page long discussion on the Lunar atmosphere entitled De Lunae Atmosphaera and printed in the previous year.[1754] Among Bianchini's friends was also the researcher of Slovenian karst, the Anglican Bishop of Derry in Ireland, Hervey.[1755]

15.4.4 Kobencl Supports Sciences in Brussels

Janez Karl Filip Kobencl studied at the University of Leyden during the late glory of the rector Boerhaave; near the University there was a famous Janez Karl Filip Kobencl studied at the University of Leyden during the late glory of the rector Boerhaave; near the University there was a famous workshop of Flemish brothers Musschenboek who, at that time, perhaps with the only exception of London, produced the best vacuum pumps and other devices worldwide. Janez Karl Philip Kobencl could not help himself, and he often went to see Musschenboek's headquarters.

Later, Janez Karl Filip Kobencl studied at the university in Würzburg; of course, he neglected moist kinds of the official exams and took over his studies in the style of the noblemen more as socializing until he became the suiter of Emperor Charles VI in 1730. As a real bon-vivant, he educated himself during his travels up to 1733. His carefree era was interrupted by his Viennese marriage with Marie-Thérèse de Palffy Erdödy (* 1719; † 25 December 1771), the daughter of the Countess Marie Margarethe Stubenberg (* 1694 Graz; † 28. 5. 1724) and Count Karl Paul III Palffy Erdödy (* 1697; † 1774) who became a Field Marshal on 5 July 1754. Marie Margarethe Stubenberg (* 1694) was the great granddaughter of the first cousin of the Protestant poet Johann Wilhelm Count Stubenberg (* 1619) who provided the first German translations of F. Bacon’s books with a little help of the vacuumist Janez Vajkard prince Auersperg (* 1615), the owner of Gottschee manor. Johann Wilhelm Count Stubenberg was also a relative of Gera (Geria, Gerra) married to the baron Androcha, the owner of manor Kostel by Gottschee.

[1754] Marković, *Ruđe Bošković*, pp. 665.
[1755] Shaw, 2001 *Bishop Hervey*, pp. 286.

Figure 15-16: Janez Karl Filip Kobencl[1756]

Janez Karl Filip Kobencl owned the castles of Prošek, Štanjel (St. Daniel), Jama, Ribnica, Planina, Šteberg, Logatec, Lože by Vipava (Leitenburg), Isernica, Sivigliano and Flambruzzo near Rivignano, halfway between Trieste and Venice, and others; for the tastes of the Hungarian reputation of his wife, he also carried the great cross of the order of St. Saint Etienne. According to the Emperor's Order (1751/59), he became a knight of the Golden Fleece together with the Parisian Ambassador Georg Adam Starhemberg;[1757] the same prestigious Argonautic Golden Fleece titles later belonged to Janez Karl Philip Kobencl's son since 1798 and nephew since 1792. In 1650, the early Golden Fleece order member became the first Prince Janez Vajkard Auersperg, the famous pioneer of Guericke’s vacuum technique; he was followed by his heirs.

In 1738, Janez Karl Filip Kobencl became the authorized minister of Lorraine, the hereditary land of the husband of Maria Theresa, Franz of Lorraine, who was raised and tutored by the father of Janez Karl Filipe Kobencl. The tutorship did not prevent the Brussels quarrels among the emperor

[1756] Villermont, *Le comte de Cobenzl.*
[1757] Sorgeloos, 1984 *Charles de Cobenzl*, pp. 126; Villermont, 1925 *Le comte de Cobenzl*, pp. 251, 252, 254, 277.

Franz's brother Karl and the son of the emperor Franz's tutor, Janez Karl Filip Kobencl.

Janez Karl Filip Kobencl became the first known Slovene freemason; he joined the lodge Zur Sonne in Bayreuth in 1741[1758] a decade after the reception of the freemason Franz of Lorraine in The Hague. The freemasonry was important part of vacuum research, since John Théophile Désaguliers (1683-1744) was among the most important researchers of new vacuum techniques: he was also the editor of the leading scientific journal of the London Philosophical Transactions and the leading freemason.

Janez Karl Filip Kobencl certainly inherited several books from his father, but he bought most of his collection himself. One of his favorite booksellers was the Normandy native Charles Fontaine (* 1724; † 1802), who founded the bookshop in Mannheim in 1742. Kobencl also bought books from Johann-Franz Varrentrapp (* 1706; † 1786), who established his bookshop in Frankfurt on Maine in 1731 and submitted 291 books to Kobencl between 14 January 1747 and 18 December 1752, including 130 books in German language.

Figure 15-17 Janez Karl Filip Kobencl's bust sculpted by of the Marseilles native Jean-Philippe-Augustin Ollivier (* 1739; † 1788) in Brussels

Janez Karl Filip Kobencl has hourly spread ~~of~~ his influence among the educators in Brussels, and his words also had a lot of power in the imperial court of Vienna. On 29 May 1767, Nény transferred to Kobencl the desire of the Antwerp printer, Jan Baptiste Verdussen III (* 1698; † 1773), that Kobencl should acquire the Jesuit Brussels library because of the expected ban of the Jesuits. The library was the most beautiful in the world, decorated by numerous discussions about vacuum techniques. Verdussen knew very well what was going on, since, with many incunabula, he kept paintings of Peter Paul Rubens and Antoine van Dyck. He was also a member of the Kobenz-based Brussels Literary Society, a later Imperial-Royal Academy. Kobencl immediately wrote back and accepted the offer as he really wished to acquire a nice picture of Antoine van Dyck.

15.4.5 Brussels Books

Janez Karl Filip Kobencl bought books for his home at the Mastaing Hotel in Brussels in numerous stores of booksellers from close ones and far Janez Karl Filip Kobencl bought books for his home at the Mastaing Hotel in Brussels from numerous European booksellers close and far. On 22 March 1758, Michael Lambert recommended to Kobencl the Journal des Sçavants, the oldest European academic newspaper, which also brought some scientific -technical news. In Strasbourg, Kobencl bought books of Jean-Geoffroy Bauer († 1783), and in Vienna his bookseller was the royal imperial freemasonic printmaker Johann Thomas Trattner (1717 Jormansforf in Burgerland-1798). Kobencl amused himself with the Journal Encyclopédique, the Mercure de France, the Gazette Britannique and the Gazette de France; in fact, Kobencl's secretaries read that stuff for him. The canon Pierre Wouters (* 1702; † 1792), the royal librarian in Brussels between 1754 and 1768, bought books from sale for Kobencl, while Kobencl himself attended the Paris sales of the late marchioness de Pompadour (Jeanne Antoinette Poisson, * 1721; † 15 April 1764) and of the Jesuit library from the Saint-Paul-Saint-Louis Church on Saint-Antoine Road in the Marais district after the expulsion of the Jesuits from France in November 1764. In 1760, Kobencl intended to obtain the books of the impoverished Scottish Parisian researcher and a member of the Parisian Academy since 1750, Michel Adanson (* 1727, Aix-en-

[1758] Košir, *Brat Vega*, pp. 105.

Provence; † 1806) after his return from a five-year research in Senegal. His nephew, Kassandra's son Coronini, also brought the books on Kobencl's behalf. Janez Karl Filip Kobencl did not hire his own professional librarians-freemasons because his nephew Janez Filip Kobencl and his young secretary Gottfried Baron van Swieten (* 29. 10. 1733, Leiden; † 29. 3. 1803, Vienna) managed the catalogues for him. Gottfried Baron van Swieten was a son of physician of Maria Theresa Gerhard van Swieten, who was replaced by the freemason Jan Ingenhousz, researcher of Fontana's gettering of vacuumed vessels and balloons. Between 1755 and 1757, since October 1757 under the control of Janez Karl Filip Kobencl (John Charles Philip), Gottfried served in Brussels in accordance with the courts' order. Gottfried later became the leading Habsburg diplomat dealing with the musicians and scientists, including the freemason Mozart and professor Balthasar Hacquet of Ljubljana; Mozart taught one of Kobencl's daughters to play piano. Janez Karl Filip Kobencl did not have the habit of writing or reading, but young secretaries preferred to do that for him, as he hired four or five secretaries together all the times.[1759]

Figure 15-18: Joseph Wright of Derby (* 1734; † 1797): The presentation of a bird's suffocating experiment in a vacuumed vessel of 1768. The type of depicted pump still raises a dust (oil on canvas, with the permission of National Gallery, London). The picture followed the style of the industrial revolution, which was promoted by the Ljubljana-native Janez Karl Filip Kobencl in his home gallery, one of the best in the world for decades.

Figure 15-19: Arthur Devis (* 1712; † 1787) painted John Bacon, his family and pneumatic instruments maker Stephen Davenport's (* 1701) table vacuum pump designed in 1737 (oil on canvas in 1742/43, with the courtesy of the Yale Center for British Art in New Haven, Conn.)

Figure 15-20: Stephen Davenport's Business card with a vacuum pump in the foreground issued in 1721.

Karl Janez Filip Kobencl's nephew-secretary Janez Filip Kobencl (* 1741) compiled one of the catalogs of Karl Janez Filip Kobencl's (* 1712) library after he studied under supervision of Viennese Piarists. His exam was crowned by Bošković's praise and there was some hot chocolate involved. Before 1739, Karl Janez Filip Kobencl's stuff compiled the first of the two library catalogs finished during his lifetime on ninety-four folio pages between today's lost covers.

[1759] Sorgeloos,1984 *Charles de Cobenzl*, p. 125; Villermont, *Le comte de Cobenzl*, p. 7, 8, 22, 88–89, 186, 216–217, 221.

Another author's catalog was created in 1761/62 on 149 folios. Each note had an Arabic number between 1 and 2000[1760] referring to the third catalog with a chronology of purchases, which is not in the record today. Janez Karl Filip Kobencl restored the library of the Duke of Burgundy (Bourgogne) in 1755, and in 1769 he strongly supported the establishment of the Société littéraire in Brussels, which became the Imperial Royal Academy of Sciences and Arts after his death, on December 16, 1772, with the help of a librarian in Leuven and later Bishop of Antwerp, Cornelius Franciscus Nelisa uit Mechelen (* 1736; † 1798).

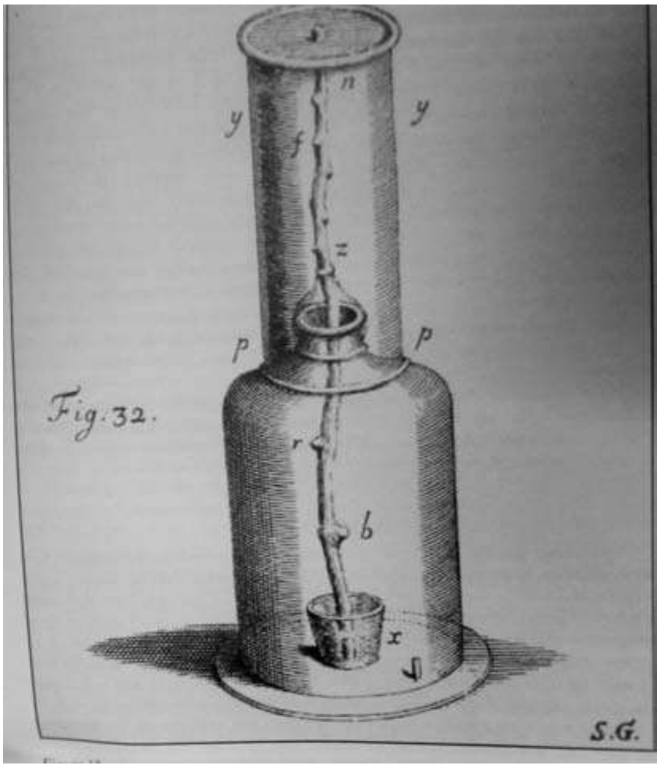

Figure 15-21: Vacuum container of English preacher Stephen Hales (1677; † 1761). On a plate that has a connection to a vacuum pump, a glassy vacuumed vessel is installed, in which Hales tested the permeability of the crust of a plant in a vacuum.*

After the death of John Charles Philip Kobencll, the curator of his estate, Nicolas-Joseph Sanchez baron d'Aguilar (1739-1822), lawyer of the Brabant, listed the deceased's library along with birds, barometers, thermoscopes, hydrometric devices, a pump and thirty-six portraits of the English royal family. The sale of Kobencl's books was entrusted to the librarian Joseph Ermens (* 1736; † 1805), who compiled a sales catalog separated in five professional fields including theology, law, science of arts, literature and history in February 1770. The sale was conducted on June 21, 1771 under the direction of the printer Henri Vleminckx. Samuel Paterson (* 1728; † 1802) published the English sales catalog of Kobencl's books in London next year, mixed with the legacies of other Dutch collectors; this was only partly an English translation of the Brussels offer, and later the prices of individual books were manually added in Paterson's printed text. Ermens has deployed 2821 books into ten expert groups. He collected nine incunabula and 80 editions from the 16th century. Around sixty books in the library of Janez Karl Philip Kobencl or 3.75% of the entire library were dedicated to mathematical–sciences with vacuum techniques included. Kobencl collected six books with mathematical content, three about astronomy, seven on physics, one on chemistry alone, one on anthropology, seven on general science, one on botany, three on zoology, twenty-three or twenty-two on medicine, four on mechanics or engineering, eleven on agriculture. four on the domestic economy and twenty-eight on military sciences.[1761]

The Brussels's political rival of Charles Philip Kobencl, the brother of Emperor Karl of Lorraine, went a bit deeper into technical sciences. He acquired 34 books on mathematics, 17 for astronomy, 38 about physics, 60 on alchemy-chemistry, 22 for geology, 25 on mechanical tools and engineering.[1762] Karl of Lorraine received 36 books about science from the Mariemont's library in 1777, which provided 7.37% of all books which Karl's owned then. Karl had 47 books about sciences in the times of his death in 1780, which was 9.45% of them all. He had ten books of Hungarian writers, but only one of American, Bohemian, Chinese, Persian or Arabic authors. At the census upon his death in 1780, Karl of Lorraine had the books of Sigaud de la Fond, Jacques Rohault and Pulian. In Brussels Karl of Lorraine read about a physics of vacuum; he read the chemistry of Nicolas Lemery and Pierre Joseph Macquer, two copies of Diderot's Encyclopedia, the work of Valmont de Bomar on natural science, the books of Duhamel du Monceau, de Condamine, the French Jesuit Jean-Baptiste Du

[1760] Sorgeloos, 1984 *Charles de Cobenzl*, p. 126–127; *Bibliothèque Royale, cabinet des Manuscripts*, manuscripta no. 20.922 in 20.919.

[1761] Sorgeloos, 1984 *Charles de Cobenzl*, p. 192–193, 199.

Halde (1674-1743) and the similar ones, which were also read by Žiga Zois in Ljubljana. Lemery, Condamine and Diderot were not missed in the library of Janez Karl Filip Kobencl either. Karl of Lorraine had a relatively large useful collection of 255 manuscripts, including drawings of electrical appliances in connection with vacuum techniques, chemistry and porcelain production, various mysterious writings including medical and chemical manuscripts of Paracelsus.[1763] Karl used to read Nurnberg based natural science journal Délices Physiques (1766/67) produced under the pen of George Wolfgang Knorr, which Kobenzl also read. Karl used the South American La Metallurgie of Alvarez Alonz Barba in the Paris edition of 1750 and the Jesuit Jean Paulus' Descriptio d'une machine astronomique, printed in Point-à-Mousson in 1762.[1764] Jean Paulus arrived in Brussels in 1763 as a watchman of Karl of Larraine and an engineer; he used modern vacuum techniques. He created Karl's clock and made another astronomical watch for the Brussels city's needs.

On 14 April 1759 the fee-thinker Janez Karl Filip Kobencl regretted the prohibition of Parisian Diderot's Encyclopedia as the continuation of Londoner work of Ephraim Chambers. Kobencl corresponded with Voltaire through bookshop Johann-Franz Varrentrap; Kobencl and his wife were a true Voltaire's admirers. They collected forty-one Voltaire's works and thirteen books about him. In 1759, Kobencl praised the book Candide ou l'optimisme issued anonymously in the same year of 1759. There Kobencl recognized the Voltaire's pen. He also had Voltaire's Elémens de la philosophie de Newton, mis à la portée de tout le monde, M. de Voltaire, printed in Amsterdam by J. Desbordes in 1738. Voltaire's essay on the nature of heat Essai sur la nature de feu, et sur sa propagation (1737), written for the prize competition of the Parisian Academy in 1739, was not published in Voltaire's collected works from 1739 and 1748, but only in 1757/58 at Cramer's office in Geneva; Kobencl bought it there. Kobencl also read the economic works of Bošković's friend the physiocrat Victor de Riquetti Marquis de Mirabeau published in 1761 and 1768. Among the summaries of the exact sciences, Kobencl loved Pierre-André d'Héguerty count Magnières's (1700-1763) Remarques sur plusieurs de commerce et de navigation from 1757. He was particularly interested in Buffon's Histoire naturelle in the Paris edition of 1749 and in Hamburg's first German translation of 1750. Réaumur's friend, the former Oratorian priest Joseph-Adrien Lelarge de Lignac (1697 Poiters-1762) immediately after the translation of Buffon's book into German language in Hamburg in 1751 published devastating critique of Condillac and Buffon entitled: Lettres à un Américan sur l'Histoire naturelle, générale et particulière de M. Buffon. Kobencl, of course, immediately bought the item. René Antoine Ferchault de Réaumur also criticized the encyclopaedia of Diderot and d'Alembert as the pure plagiarizing, which was certainly not entirely true. The freemason Benjamin Franklin supported Buffon's side.

Kobencl also read the Parisian Dictionnaire raisonné universel d'histoire naturelle of 1764, written by the pen of Jacques-Christophe Valamont de Bomare (* 1731; † 1807). Kobencl also kept the fifth edition of the Parisian Elémens des mathématiques, perhaps acquired already during Kobencl's youthful journeys. That Bernard Lamy's book was published by the Parisian widow Delaulne in 1731. In the same year under the similar title the fans of Jesuit Pierre Varignon (* 1654, Caen; † 23 December 1722, Paris) posthumously published Varignon's mathematics in Parisian offices of Brunet. In 1688 Varignon became the member of the Geometric Department of the Parisian academy and professor of philosophy at the Collège de France where he promoted his invention of U-tube manometer capable of measuring rarefaction in gases.

The second Amsterdam edition of Lamy's mathematics from 1682 was also kept by Baron Erberg in Ljubljana and later in Dol. At the age of eighteen, Lamy began studying in Paris. Four years later, while he was learning rhetoric (last year of lower studies), Malebranche met him and remained his friend until his death. In 1671 and 1672, Lamy taught philosophy at a college in Saumur and then in Angers. In Angers he defended then still banned Cartesian philosophy against vacuum, therfore the king Louis XIV has removed him in 1676. After four years of exile, he continued his teachings in Grenoble. In 1679 he published a mechanics with the rule for summing forces in a parallelogram, which was at the same time described by

[1763] Sorgeloos, 1984 *Charles de Lorraine*, p. 830.
[1764] Sorgeloos, 1984 *Charles de Lorraine*, p. 825, 827–828, 830, 832; Kobencl & Paterson, *A catalogue*, p. 88.

Varignon. Lamy's book was so popular that it was reprinted in 1687 at the time of the publication of Newton's Principles. In 1685, Lamy supplemented his mathematical textbook with geometry. The following year he was granted permission to return to Paris, but because of theological contradictions he left for Pascal's Rouen in 1690. There he published a paper on the perspective in 1701.[1765] After his death, Lamy's mathematical-physical works were published in Amsterdam in 1734.

Janez Karl Filip Kobencl kept Jean Hellot's French translation of the work of the German Christopher-André Schlüter De la Fonte des Mines des fonderies, des grillages, des fourneaux de fonte, affinage, de raffinage, des fabriques de vitriol, de potasse, etc., printed in Paris between 1750 and 1753, which he had been using to advance the technology and economy of the Habsburg Netherlands. He also acquired a very influential Haller's Elementa physiologia corporis humani (Lausanne, 1757-1766). For a general overview of novelty in science and vacuum techniques, Kobencl afforded the simple parts of *Le Spectacle de la nature, ou Entretiens sur les specificités de l'Histoire naturelle qui ont paru les plus propres à rendre les jeunes gens curieux et à leur former l'esprit*, printed in Amsterdam in 1743. It was first published in 1732 while Zois acquired the later edition of 1752. Kobencl also had the mythological astronomy *Histoire du ciel* (Paris 1740) which Carli used in Italian translation *Istoria del cielo*, while Zois acquired *La mécanique des langues, et l'art de les enseigner* printed in 1751. All those three successful books were written by priest Noel Antoine Pluche (* 13. 11. 1688 Rems; † 19/11/1761 Paris), a professor of rhetoric and a school rector in Rems. Pluche was never really a Newtonian; he preferred Abbé Joseph Privat de Molières' compromise between Newtonian physics and Cartesian vortices, while in fact Pluche criticized both, Newton and Descartes.

[1765] Cantor & Cajori, 1908, 4: 603.

Kobencl had at least two Leibniz's books, as well as works by Christian Wolff.[1766] The contemporaries used them for teaching physics and vacuum techniques everywhere in the empire including Ljubljana.

Among the most important works on early vacuum techniques obtained by the Ljubljana native Janez Karl Filip Kobencl, was the work of Denis Papin[1767] issued in the time immediately after Papin's work in the position of director of experiments at the Venetian Accademia publicca di Science, a public academy, which Kobencl knew well. The Venetian academics acted on the model of the Royal Society of London, and mainly dealt with Boyle's vacuum experiments, in which Papin himself had a good share. Upon Kobencl's death, Papin's book was estimated to relatively low value. It was worth 1 florin and 8 coins (kreuzers). It brought many novelties from the then vacuum technique.

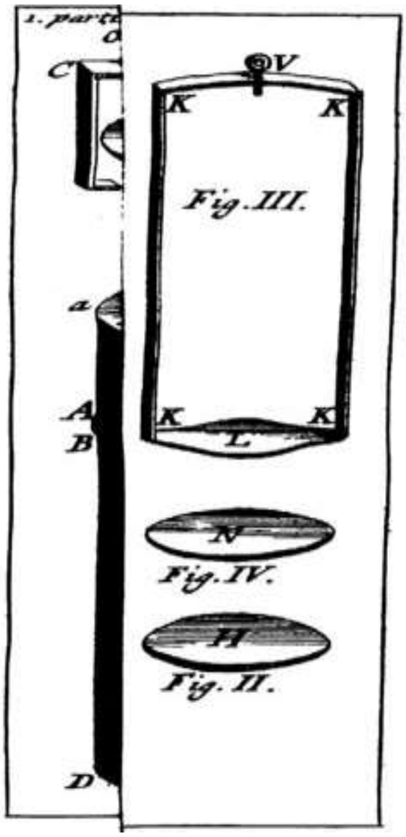

Figure 15-24: The Papin's container staged at the end of the first part of his 1688 book. It was used by Papin's reader Kobencl to host his famous guests.

Figure 15-25: Denis Papin (* 1647; † 1712) in the best days

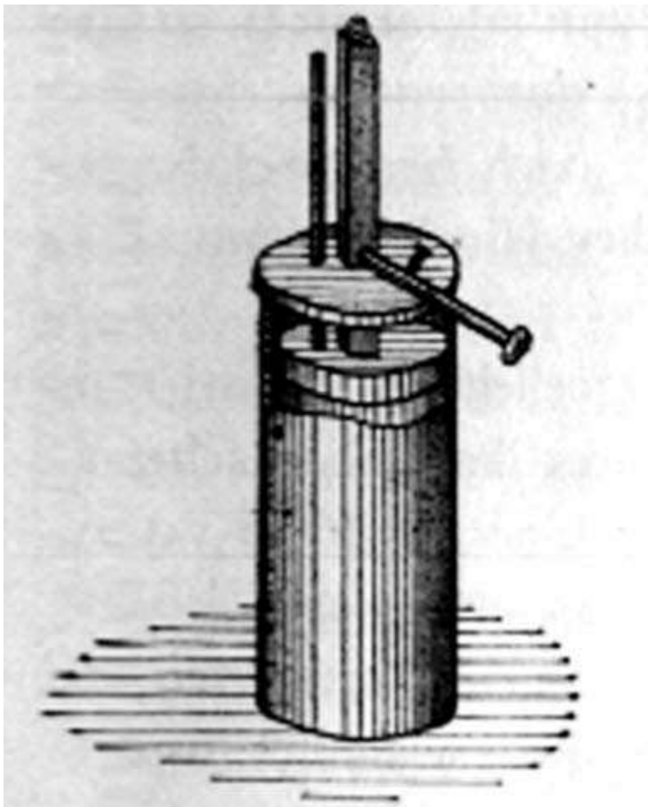

Figure 15-26: Papin's high-pressure cooker

Janez Karl Filip Kobencl obtained the book Gründlichen Nachricht von dem in dem Inner-Crain gelegenen Cirknitzer See of Franc Anton von Steinberg (* 1684, Kalec near Zagorje in the

[1766] Sorgeloos, 1984 *Charles de Cobenzl*, pp. 150–151, 156.
[1767] Kobencl & Paterson, 1772, 76, under no. 1848.

Karst; † 1765, Ljubljana), published in Ljubljana by Ana Elizabeth, the widow of Reichardt in 1758, on 235 pages with 34 copper plates. The book was distributed by Kobencl among friends. The Kobencl's catalogs mention as many as twenty-five copies of Steinberg's work, and one of them was given to Kobencl's co-worker, Nény. In the bookstore advertisement of the newspaper Wochentliches Kundschaftsblatt, Ljubljana's Promberger published one page with twelve new books he offered; among them was the booklet on the Lake Cerknica of Franz Steinberg for 1 fl. The provincial Governor Janez Gašper Kobencl encouraged Steinberg's work already between 1718/20; that is why Steinberg dedicated the book to Janez Gašper's son, Janez Karl Filip Kobencl, together with the seven pages of praise, and in 1761, Janez Karl Kobencl allowed the publication of a shortened translation at the Royal Press Office in Brussels under the title Le lac merveilleux ou description du lac de Czirknitz en Carniole, et des ses principales singularités Phisiques. Tirés de l'allemand de Steinberg. The work was dedicated to the Countess Kobencl on fifty-nine pages with a copperplate. At the same time the French translation and the reprint of the German edition were published in The Hague and in Graz. The Graz version differs from the Ljubljana redaction only by the publisher.

Steinbergs and Kobencls were ancient Inland cousins, although Steinberg's father was financially damaged by the loss of money invested in the breeding of Lipizzaner horses, so he had to sell his manor in Kalc and move to Cerknica Marof when Francis Anton Steinberg was only three years old. Steinberg's early textbook was N. Bion's masterpiece full of sets of measuring devices for vacuum and related experiments,[1768] with which Steinberg checked the operation of his inventions for the mine in Idrija. After his schoolings in Ljubljana, Steinberg studied mechanics, and he began to learn the modern vacuum techniques. Between 1712 and 1724 he was an official of the Imperial Court Chamber and the mining commission, then he became the investigator of forests, roads, and sea in Rijeka (Fiume) and later the supervisor of regional roads in Carniola. Between 1724 and 1747 he was the manager of the mine in Idrija, where he enriched the mining collection with many utensils based on modern vacuum and watchmaking techniques; for many years Idrija was an unique capital of vacuum research because of the uses of Idrija mercury in barometers. Unfortunately, Steinberg did not understand well Scopoli, a physician who believed in the doctrine of phlogiston theory until the end of his days.

Janez Karl Filip Kobencl did not only help Carniolan writers. He even paid for the printing of the historical book by Robert Macquéreau de Valenciennes, edited by the Hebraist and bibliographer Jean-Noël Paquot (* 1722; † 1803) with a reference to Kobencl's name in the introduction. The nephew of John Karl Philip Kobencl, the Count Janez Philip Kobencl, aroused similar great ambition; he paid for the German translation of Euler's Latin papers on comets from 1744, which was translated by a jurist, diplomat, architect, astronomer, vacuumist and mathematician Janez Krstnik baron Paccassi. Paccassi collaborated with Gruber's teacher, Karl Scherffer and Abraham Gotthelph Kästner, whose

[1768] Korošec, 1967 *Beseda dve o Steinbergovem*, p. 16; Sevnik, 1988 *Steinberg*, pp. 458.

book Gabriel Gruber used during his lectures in Ljubljana. Paccassi was accepted into the Berlin Academy of Sciences just like Euler and Lambert; he also closely cooperated with them. Janez Baptist Paccassi translated the legal documents of French Finance Minister Jacques Necker (* 1732; † 1804) in Vienna in 1781. He was a descendant of court architect of Schönbrunn, Nikolai Frančišek Leonard Paccassi (Nikolaus Franz Leonhard, * 1716, Viennese Neustadt; † 1790, Vienna), who became a member of the Viennese Academy of Arts in 1768 and baron on 15. 7. 1769. The stonecutters Paccassi rose to European fame through their work for local Gorizia magnates including Coronini.

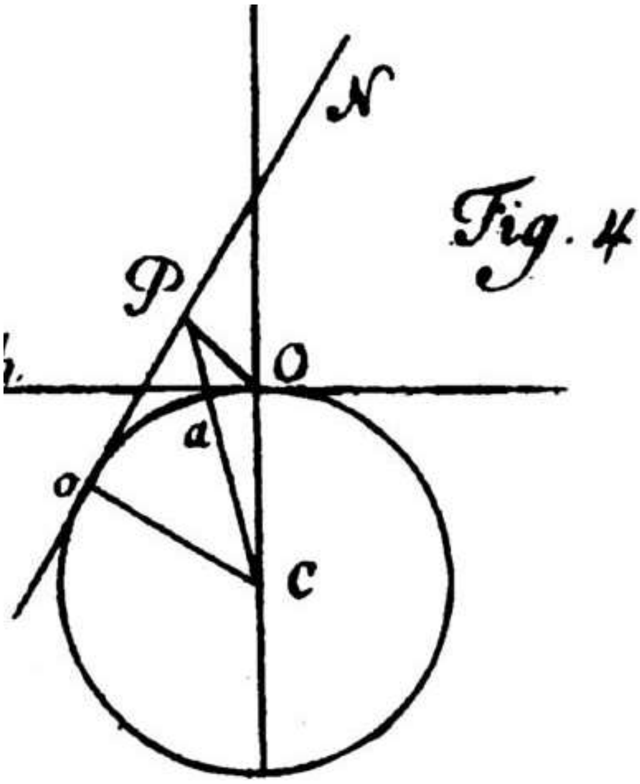

Figure 15-28: A picture at the end of Paccassi's Book of Navigation which discussed the filled and vacuum balloons

In 1784, immediately after the first French experiments by Montgolfier brothers, Janez Baptist Baron Paccassi published mathematical calculations of the possibility of directing flights with balloons; he judged them as impracticable, due to the thickened wall of the balloon, rejected the idea of the Jesuit Lana Terzi on a vacuum aircraft.[1769] He was thinking of an elliptical balloon and checked the resistance by the Euler's equations of mechanics. He calculated a curvilinear movement of a balloon caused by changing of the external pressure along the path of the lifted balloon at the border of vacuum measured by a mercury barometer; in this case, the vacuum was formed above the column of Idrija mercury. By his first approximation he ignored influences of the gravity of adjacent planets according to the calculations of geologist Barthélmium Faujas de Saint-Fond (Barthélémy); he used Saint-Fond's French description of Montgolfier's flight, which was also read by Žiga Zois in Ljubljana, Faujas de Saint-Fond criticized the bad German translation of Franz Übelacker since Faujas de Saint-Fond was certain that Übelacker did not master modern mathematical and vacuum techniques.[1770] Janez Baptist Baron Paccassi also applied for the prize competition of the Parisian Academy focused on the piloting of balloons. Already during the printing of his book, he heard about the filling of balloons with carbon dioxide developed by the then vacuum researchers; the novelty was immediately offered to readers in his appendix.[1771]

The Kobencl family name without male heirs disappeared on the southern slopes of the Alps well over two centuries ago. Perhaps in their last two generations, a similar mistake has been made as in the last two generations of the Counts of Celje three and a half centuries earlier: they wanted to grasp as much political power as possible while forgetting all about the centuries of Habsburg wisdom: the power is retained with as many children as possible. Like the old Celje family, Kobencl's genus became extinct as they spent to much time in political intrigues instead of producing their own children, but by no means before they were magnificently written in the golden letters in the history of Slovenian diplomacy. In their time Celje rulers built their power on the accumulation of profitable manors, while Kobencl played on modern techniques, Freemasonry associations and on a high society of the Viennese policy itself. In contrast to the Celje rulers or the Auerspergs, the Count Kobencl never received the honor of prince, but they certainly did not regret that on the eve of Napoleon's abolition of the Holy Roman Empire of the Germanic nation with all its princes included. While the weapons of the Celje magnates were sables, the Auersperg

swore to their good governance at the Lower Carniola (Dolenjska) region or the Sudeten region, and to vacuum experiments under Guericke's auspices. Besides their Inner Carniola and Littoral manors Kobencl's toolkit was mostly advanced up in the salons of the then social cream, where famous books about new vacuum techniques and other puzzles of the modern era were read and discussed.

15.5 Gian Rinaldo Carli - First Professor of Technical Sciences from the Area of Present-day Slovenia

15.5.1 Introduction

The Carniolan Count Kobencl can be placed along the side of the Count of Carli, who established themselves not far away from the state border in Venetian Koper. The high school, now known as the Gian Rinaldi Carli Gymnasium in Koper, was founded as Collegio dei Nobili in 1612 by Corpo de Nobili as a body of the Council of the City of Koper (Consiglio comunale). It was the first lay school in Koper; its initial purpose was to oppose Protestants in the spirit of the Tridentine Council during the awkward time after the devastating wave of violence called the Uskok War or the war for Gradisca (Gradišča); the fights ruined in Istria between 1615 and 1617 and impeded the functioning of the school along with infectious diseases, so that uninterrupted teaching operations began only in 1675.[1772] The Somaschi fathers used the help of monks from other Catholic orders to administer their school in Koper. In 1676, Vincent Ferra from the Koper Dominican monastery taught the logic and philosophy in Koper. Immediately after the construction of the college building, between 1684 and 1687, mathematics and chemistry were taught in Koper by Franciscan trainee Michel Angelo Fardella (* 1650, Trapani, Sicily; † 2. 1. 1718, Naples). After entering the third Franciscan order (Order of Penance of Saint Francis) after three years of teaching became a priest in the year 1665. He studied in Messina with Giovanni Alfonso Borelli~~o~~ (* 1608; † 1679), a student of Benedetto Castelli and Galileo, who knew well then available vacuum techniques. Fardella taught mathematics and theology in Rome after 1676. Between 1678 and 1680 he became a Cartesian opponent of the vacuum after talks with D. Cassini, Spinoza's critic Pierre Sylvain Régis (* 1632; † 1707), Antoine Arnaud, Nicolas Malebranche and Bernard Lamy. In 1680, he returned to Rome for his second time as a lecturer in the mathematics instead of the recently deceased vacuum researcher Kircher. He then responded to the invitation and in April 1681 began teaching the philosophy in Modena, where since 1679 he worked with Micheal Angelo's half-brother Tomasso Fardella († 1694), a tutor of the marquess Bonifacio Rangoni, the first president of the Academy of Dissonanti established in Modena in 1683. Michel Angelo lectured on logic and mathematics in Modena in 1681/82; in 1682/83 he taught physics with chemistry and geometry, and in 1683/84 metaphysics, that is, the entire three-year course of philosophy. In 1683, he went back to Rome, where he published Conclusiones (ad) mathematicae and polemized with Jesuit Giovanni Francesco Vanni about the experiments; in Rome he also published *Restitutee ac methodicae philosophiae et matheseos principie, and utiliores assertiones*. There in his *Prolusio* (introduction) he defended 222 scientific theses, arranged in seventeen sections, including astronomy, physics and the pneumatics as the knowhow about gases and vacuum. In 1684, with half-brother Tommaso, he went to Koper, where Franciscan trainee Michel Angelo taught for three years as a public lecturer in philosophy (physics and mathematics), while lawyer Tommaso Fardella was the rector in Koper between 1685 and 1689.[1773]

In 1685, Michel Angelo Fardella visited Rome, where he unsuccessfully tried to get the chair at a mathematical department of Sapienza University. Vitale Giordani (* 1633; † 1711) got that prosperous chair as he was also a friend of Borelli, one of the founders of the Florentine Accademia del Cimento in 1657, Michel Angelo Fardella taught in Venice between 1687 and 1709, where the commander of the city Fletre by Belluno northwest of Venice Almora Dolfin (Almorò) hosted him and his half-brother Tomasso Fardella. In Venice, in 1689, Michel Angelo Fardella as Cartesian had his hardest times with a local inquisition. He taught Astronomy and Philosophy in Padua as a unique predecessor of Gian Rinaldo Carli between 1693 and 1709, after becoming a secular priest. Between 1709 and 1713 Michel

[1772] Žitko, 1994, 127–128.

[1773] Pusterla, 1891, 41.

Angelo Fardella was in Barcelona, and then returned to Italy. He was in contact with the opponents of the vacuum Leibniz after their meeting in Rome in 1690; this prompted Michel Angelo Fardella to reject the genuine criticism of Cartesians provided by the Matteo Giorgio in Genova 1695 and 1698. In 1691 Michel Angelo Fardella communicated two Natural Historic scientific books in Venice in Girolamo Albrizzi's (Albritus) edition, and in the following year he published the third one in Amsterdam in the office of Paolo Antonio Sanzonio. In 1698, Girolamo Albrizzi published anti-Cartesian views provided in the letters of Matteo Giorgio, Michel Angelo Fardella, and the physician of the pope Innocent XII (1615-1700) Luca Tozzi (1638 Frignano–1717 Napoli) in *La filosofia cartesiana impugnata in alcuni principi dal dot: Matteo Giorgi genovese, e difesa dal signor abbate Michel'Angelo Fardella professore d'astronomia, e Meteore nello Studio di Padova Consacrata all'illustrissimo monsignor Luca Tozzi medico di Sua Santità in Venezia*.

In 1986, in Naples Michel Angelo Fardella's fans reprinted his scientific opinions and letters against the Scholastics.[1774] The modern edition surely means that Fardella's ideas, developed in Koper, still have a notable echo.

The count Gian Rinaldi Carli was born two years after Fardella's death. A century after the founding of the Collegium of Nobles, Carli studied there. Differently from Fardella, he preferred Newton to Descartes. Carli was one of the most prominent erudite of Koper which is why his name is today used for the gymnasium with an Italian learning language in Koper. Another interesting feature is in the Gian Rinaldo Carli's networks: although his knowledge covered other major centers of northern Italy, he remained present in Koper himself as a not always quite successful entrepreneur, but above all a scientist, lover and collector of (good) books. There was already a lot of ink spent on Carli's work in various fields of humanities and economics. Here we describe his research on chemistry, physics and related fields which became his first love after he barely left the student bench and began to lecture on the newly established chairs for nautical sciences, ship architecture and astronomy with geography in Padua.[1775] Quite early, Carli accepted new scientific achievements of his times, including modern vacuum pumps. He read the books of Keill, who was among the first to teach Newton's physics. The work of these famous men was already known to Carli in Istria, after Halley befriended Valvasor; between 1701 and 1703, Halley drove across Trieste, Istria and Kvarner, searching for suitable ports for the planned disembarkation of the English and Dutch Navy assisting Habsburg Emperor during the War of the Spanish Succession. In 1718 Halley assumed that the stars had changed their positions from the Argonauts' era.[1776] The young Halley once published Newton's Principles with his own money. Newton's work, and with it many other stars of contemporary science, could not wish for a better recommendation than offered by Halley. He was the captain of the English navy and a visitor of all kinds of fairs in Trieste, Rijeka or Istria, although he finally preferred to fortify Bakar Bay for the planned disembarkation. Thus, Newton's achievements after Halley's mediation in Istria have been well-known for two decades before Carli's birth. Nevertheless, Carli was honored as the first to writer about modern physics, chemistry and vacuum techniques among the Istrian people; so, Carli was one of the first modern researchers not only south of the Alps, but also throughout the Continental Europe outside France.

15.5.2 Vacuum Techniques by Paduan Professor Carli

Less than three years after the end of his happy Paduan student days, Carli took up a newly established chair for the theory of nautical sciences and and shipbuilding at the University of Padua with a salary of 300 florins on 21 April 1745.
Marquess Scipione Maffei and Giovanni Poleni (* 1683; † 1761) have rearranged Paduan studies of mathematics with physics and chemistry and astronomy in Padua; At the suggestion of Giovanni Poleni, Jacopo Stellini and Marc Foscarini, the young twenty-five-year-old Carli was appointed professor at the newly established department. An aid to Carli's academic prestige was his publication, which made Carl's lectures interesting for the school of the Venetian arsenal. At the time of Carli's lecturing the university of Padua founded a chair for natural sciences (1734), experimental philosophy (1738) and the basis of

[1774] Fardella, 1691, 1695, 1986.
[1775] Del Negro, 1997, 153, 156.
[1776] Hoskin, 1978, 239.

geometry (1741); the latter worked only until 1751.[1777]

Because he was so very young, Carli probably did not fully absorb his so-called academic duties,[1778] but nevertheless he took his scientific position in extreme seriousness; and consequently he published two of his most important books devoted to mathematical and natural sciences related to vacuum and magnetism.

As a new professor of mathematical and naturalistic technical (exact) sciences at the prestigious Paduan chair, Carli emphasized, of course, the areas of knowledge that he most praised. Particularly important was the use of magnets in compasses, tidal studies, the elimination of inaccuracies in clocks and the knowledge of the movements of the compass.[1779]

Carli used the measurements of magnets of Thomas Savery's relative Servington Savery (* 1669; † 1744 Shilstone in Devonshire) published in 1730 in London's Phil. Trans. At the same time, he read the famous work of vacuum researcher Pieter Musschenbroeck De Magnete,[1780] which was also extremely popular in Ljubljana. Carli praised the works of Bernard Zendrini, a professor of mathematics from Venice, who compiled his own compass in 1714. According to Zendrini's example, Carli also designed his own version of compass in Padua.[1781]

15.5.3 Carli and Tartini

The Piran native Tartini corresponded with Koper native Carli. Tartini praised Bošković as the greatest mathematician in Europe. At the same time, Tartini corresponded with other important mathematicians of his time, although some of them were not friendly to him, nor to Bošković. Among the recipients of Tartini's letters were: G. Riccati, F. Algarotti, Jacquier, Le Seur, Lalande, d'Alembert, Beccaria, Nollet, and Euler. French professor of mathematics Le Seur of Parma and Jacquier from the La Sapienza University in Rome were close associates of Bošković; they became famous with the commentary translated of Newton's Principles, published in 1739 and 1742. Tartini also shared the common friend Lalande with Italian defenders of Bošković; Tartini contributed greatly to the acceptance of Bošković's concept of the world and of the vacuum in northern Italy, which was short-lived. Carli was a genuine Tartini's friend, but Bošković was, nevertheless, Carli's political opponent during Carli's efforts to limit the Jesuit influence on high schools in Milano and Pavia.

15.5.4 Electricity

The modern science has already successfully attacked magic in the era of Carli. The Inquisition was also involved in the dispute as it penalized by the Lombard laws. Carli resolutely opposed magic and the beliefs in witches already as a student; his opinion was later aggravated against Kabbalists, Pythagoreans and Astrology. On 5 October 1743, Carli wrote to Tartarotti on artificial memory, a very popular topic of the then scholars. Girolamo Tartarotti noted his ideas in an annex to the collection of one hundred thirty-four magic observations; followed by the addition and letter of Congress (Congresso Notturno delle Lammie), which were exchanged mainly by Clemente Baroni Cavalcabò (1726 Sacco in Trentino–1796 Sacco) and the Abbot Tartarotti from Rovereto in Trentino between April 1750 and April 2nd, 1751. In the first letter on 18 June 1749, Ludovico Antonio Muratori in Modena criticized the letter of Paduan professor Carli, sent to Tartarotti in 1749 and published in the documents of the Congress; Carli rejected the supposedly wrong doctrine of legendary mages from the time of Jesus's birth. On 8 July 1751, the Abbot Tartarotti dedicated his book to Francesco Giuseppe de Rosmini in Rovereto. Already in the introduction, he refused Carli's adverse opinion of the diabolic magic, which they discussed during the congress in 1749.

S. Maffei and Tartarotti exchanged views with their companion Bartholomew Melchior; their thinking was in many respects based on the still popular Del Rio's instructions to judges in witch-hunt processes. The Jesuit Del Rio strongly opposed magic; as the Dean of the Theological Faculty in Graz, he lectured on the Old Testament between 1600 and 1603. The work of Rio was read

Table 15-1: Important scholars and writers whom Carli quoted in his book on the Argonauts in 1745

Name	Year of publication, title of the book, place of publication	page of Carli's quote
Cornelius Agrippa		50
Peter Apian		44
Aratus, Solensis (Ἄρατος ὁ Σολεύς; c. 315 BC/310 BC Soli in Cilicia of today's Turkey – 240) as a Greek didactic poet. Hi), the antique writer	1589, *Phænomen. in Astron. Vet. Script. (*Astronomica veterum scripta isagogica Graeca & Latina*) Heidelberg: Offic.* Sanctandreus	28
Archimedes		56
Niccolo Bion	*Traité de la construction et des principaux usages des instruments*	55
Count Buffon	1749, *Historie naturelle, Paris*	XIII
	Libro de' Cavalieri erranti nicknamed *Tavola ritonda*	12
Philipp von Zesen (Filip Caesio, * 1619; † 1689)	1662, *Cœlum Astronomico-poeticum, sive, Mythologicum stellarum fixarum,* Amsterdam: Bleu	4, 7, 19, 29
Natale Conti	1612, *Mythologia*, Geneva	7, 53
Abbot Antonio Conti	1726, *Réponse aux observat. sur la Chronolog. de M. Newton e Lettre de M. au sujet, d'un petit écrit intitulée Réponse ec.*, Paris	
Vicenzo Coronelli (* 1650; OFM, 1665; † 1718), geographer of the Venetian Serenissima	1693, *Epitome Cosmografica* ..., Köln: Poleti	34
Aesop		41
Valerio Flacco (Flaccus)		18, 74, 77, 89
John Flamsteed	1725, *Historia Cœlestis Britanica,* London	29
Alberto Fortis	1771, *Saggio D'Osservazioni Sopra l'isola di Cherso ed Ossero*, Venezia: Gaspare Storti	(Carli, 1785a, 70, 74)
Pierre Gassendi		54
Halley		XIII, 47
Herodotus	*Epistola; Rursum in Chersonesum (in Crimea)*	18, 19, 76
Hipparchus		51, 94; (Carli, 1785a, 78)
Hippocrates		43
Philippe de la Hire	1735, *Tables astronomiques*, Paris	46
Homer		22, 86
Gaius Julius Hyginus (1st century)	1642 or 1670, *Poeticon astronomicon.* Leyden/Amsterdam	42
Keill		46
Athanasius Kircher	*Museo Collegio Romano*	81
S. Maffei		XI; (Carli, 1785a, 77)
Count Giammaria Mazzucchelli	1737, *Notizie Istoriche e critiche intorno ad Archimede*, Brescia: Rizzardi	56–57
Mela Pomponius		77, 84, 86

Giovan Francesco Pico Mirandola		50
Newton	1728, *La chronologie des anciens royaumes corrigée*, Paris	42, 45, 46, 51, 53, 57, 59, 60, 61, 140, 281
Abraham Ortelius	*Argonautica.* Antwerp	49, 79
Dionigi Petavio	1710, *Rationarum Temporum*, Leyden (reprints: 1720, Köln: SJ (NUK-25288); 1741, Verona: Berni (NUK-72356); Astrology in his work: 1627, *Opus de Doctrina Temporum*, Paris	42, 281
Paduan professor Alessandro Piccolomini (* 1508, Siena; † 1578)	*Della sfera del mondo*, Venezia (first printed atlas of stars published in 1540)	54
Gajus Pliny Secundus, senior (* 23/24)	*Naturalis historiae libri XXXVII* with astronomy in second and geography in third book (Pliny, 2009, 24)	82, 85
Plutarch	*De musica*	53
Giovanni Poleni		29
Eusèbe Renaudot (* 1613; † 1679)	1736, *De l'origine de la sphère*, Paris	54
Joseph Justus Scaliger, Leyden professor of literature	1680, *Propers. Luog Traiect. Rhen.*	88
Johann Scheffer	1654, *De militia navali*, Uppsala	19, 23
Janez Ludvik Schönleben	1681, *Annal. Carniolae*, Ljubljana	79
Sesto Empirico	1569, *Advers. Mathemat.*, Paris; 1718, *Non ligna admirantes.* Leipzig	45, 50, 57
Étienne Souciet		XIII, 46, 47
Strabon	1705, *Geografia*, Leyden	4, 55, 64, 82, 89; (Carli, 1785a, 80)
Brooke Taylor		46
Marcus Vitruvius Pollio		50, 53
Giannantonio Volpi, professor of literature in Padua		19

in Stična and elsewhere in the Slovene lands. The Cistercian, Janez Krstnik David Radio, wrote in 1776 his own ex libris "Ad Usum" into Tartarotti's report on Congresso Notturno delle Lammie. Carli's friend S. Maffei published on magic in 1750 and 1754.[1782]

After his academic problems in Padua Carli dealt with numismatics from a historical point of view, which soon led him to money and economy. By the mediation of Kaunitz and Firmian Carli got a high-ranking Milanese job. Although he was a contributor of the famous newspaper Il Caffè, for his different Koper native basic feelings, Carli soon came into conflict with the editor of Il Caffè Pietro Verri. Their quarrels also reflected the opposite views promoted by the administrations of Kaunitz and Firmian. In the high-profile L'uomo libero, which Carli finished in the spring of 1776, Carli, as Habsburg politician, rejected Rousseau and Verri. The first edition had a fictional place of printing put in Lyon; afterwards, that Carli's masterpiece went through numerous editions.

Initially, Carli concealed his authorship to escape the quarrel. Similarly, in 1780, he attributed the wrong place of publication named "Cosmopoli" to his Lettere Americane, where he recounted again with Rousseau, later Parisian Mayor-Astronomer Jean-Sylvain Bailly (1736; † 1793) and Buffon. In 1792, in his Della diseguaglianza fisica, Carli

[1782] Trampus, 1997, 143–145, 147, 148, 150; Maffei, Tartarotti, Melchior, Cavalcabò, 1751, 1, 2, 46, 106, 225–268; Trampus, 2004, 8; Mlinarič, 1995, 787, 795, 796, 934 completely rejected the French Revolution. Between 1784 and 1793, Carli released his collected works in which he changed many of his two decades older ideas. In 1797 in Venice, Carli's L'uomo libero was reedited in such funny way that the former Carli's defense of absolutism suddenly transformed into an opposite defense of the Republicans.[1783]

In the ninth volume of his collected works, in 1785, Carli also reprinted his letters about witchcraft under the title Dissertazione epistolare sopra la magia e stregheria, published by the Tartarotti's Congress of Notturno delle Lamie in 1749.

Carli knew the research of blood and arteries, explored by the Paduan student Harvey and Haller in their experiments on adapted veins of the dead folks. Carli was interested in the experiments of the priest Felice Fontana, who directed Ingenhousz to the discovery of photosynthesis. Fontana's research of the getters opened a new page of vacuum technique.

Carli rhetorically wondered what gravity used to be before the works of Galileo, the weight of the air before Torricelli's vacuum experiments, the optical theory before Newton, the transpirations before Koper native Santorio or the blood circulation before Harvey? Carli believed that the theory of caloric designed by Adair Crawford explained the blood circulation. Carli admired experiments with distillation and burning of the vacuum researchers Boyle, Boerhaave and Hales. Like light, the heat, blood circulation, or even life itself are also dependent on motion. If we stop the movement, nothing is left to the vitalism theory of the blood circulation of the Modesta university professor knight Michel Rosa (* 1731; † 1812), explained in his five letters sent to Carli and published in 1781. In 1783, the Professor Scopoli of Pavia, a former Idrija doctor, translated Macquer's chemical dictionary by defending phlogiston, which allegedly could describe Crawford's theory very well; of course, everyone with Carli included was eagerly awaiting new contributions by Knight Rosa.[1784]

Carli published his discussion of Della memoria artificiale about then very popular topics of artificial remembrance on 22 March 1793 with Abbot Bettinelli from the Academy of the City of Mantova. Next year it was reprinted in the 19th volume of Carli's collected works. Carli there recalled the ancient Francis Bacon's thoughts on artificial memory. He also knew the views of Christian Wolff from 1738. He was interested in the opinions published by Gassendi, Plato, Epicurus, Locke, Locke's defender Abbot Étienne Bonnot de Condillac (* 1715; † 1780) and Pascal.[1785]

Carli was aware that the animal's electricity travels through the body (Carli, 1794, 19: 68-69) By discussing the works of the professors of Volta and Galvani, Carli compared the electrical effects of Leyden jar with a heart stroke in his *Opuscoli scelti di Milano*; the cardiac stroke seemed to him to be very like a blow from the Leyden jar. He assumed that most of the body movements were due to electrical phenomena and are therefore influenced by external and internal weather phenomena, which Carli linked to the bad habit of the current doctors, prone to excessive leakage of the blood of their patients. Leibniz attributed a lot of movements to the vibrations undetectable by experiments of those days. They resembled the vibrations of the bell. On 6 October 1792, Carli's association between animal electricity and heartbeat was published by the secretary of the Società patriotica di Milano Amoretti under the title Sopra l'elettricità animale, e l'apoplesia. Carli was interested in Galvani's research of animal electricity, published in 1791. Carli also used Volta's discoveries in Pavia and the publication of Giuseppe Gardini at the Mantua Academy in 1788. Carli was aware that Aristotle and Pliny had already been researching animals that produce electricity; he particularly emphasized Maffei's experience described in 1731. He electrified a 64-year-old woman before the publication of Franklin's theory. Maffei was interested in the properties of phosphorus in connection with animal electricity.[1786]

In a tenth part of his collected works, Carli published his researches on the Argonauts, and in 11th-14th parts of his collected works Carli republished his Lettere Americane. Dr. Hooke published An Essay towards a Maschinel account

[1783] Trampus, 2006, 465–466, 473, 475; Costa, 1997, 206.

[1784] Carli, 1782, 101, 215, 216, 234, 248, 250–251, 257, 258; Stancovich, 1829, 371; Carli, 13. 6. 1782, 265–266.

[1785] Stancovich, 1829, 381; Carli, 1794, 19: 3, 29, 45, 46, 48, 64–65.

[1786] Carli, 1794, 19: 73, 76, 395, 396, 399, 400, 404; Bossi, 1797, 239; Carli, 1794, 19: 395; Stancovich, 1829, 382.

of memory; Carli surely had in mind Robert Hooke, who really presented in front of the Royal Society on June 21, 1681. Hooke lectured on mechanically conceived artistic memory under the title An Hypothetical Explication of Memory; how the Organs made use of the Mind in its Operation may be mechanically understood, which was printed after Hooke's death in 1705. Malebranche, the knight Rosa, Volta and Galvani also thought of similar problems.[1787]

15.5.5 *Upgrading the Education of Chemistry and Related Sciences in Lombardy*

Carli, together with his friend Botanist Vitalian Carli, together with his friend the botanist Vitalian Donati (* 1717, Padova; † 1762), explored the cave called Grotta Santa at St. Servol (Sveta jama by Socerb Castle) with a nearby underground "church" not far from Carli's native Koper. Carli examined those stalagmites and stalactites again later in his Lettere Americane. He discussed the phosphorescence of the sea by ideas of the French Nollet, whose prominent electrical experiments opposed Franklin's ideas. Carli commented Maupertuis' works and the book of Vitaliano Donati published under the title Della Storia Naturale Marina dell Adriatico: Saggio in Venice at the office Francesco Storti in 1750.[1788]

Luigi Giusti (* 1709, Venice, 1766), the Viennese minister of Italian affairs (segretario del dispaccio nel Dipartimento d'Italia a Vienna), proposed Carli as a president of the Magistrata Camerale de Milano in 1760 which was profoundly reformed in those days. In 1765, Carli in Vienna assumed the duty of Commendatore di S. Nazaro, and on 20 November 1765, with the appointment dated 10 December 1765, he became president of the Supremo Consiglio di pubblica economia and later the president of the new Chamber of Commerce (1771- 1780). Among his associates were Pietro Verri (1728-1797) and young Milan patrician Angelo Maria Meraviglia Mantegazza († 1766), who died within three months. After the lectures in Padua and the death of the Venetian doge Foscarini, the Venetian authorities somewhat resented Carli. Therefore, during next decades, he operated under the Hapsburg Squad in Milan in leading administrative and economic positions. He also became dean of studies (Decano del Tribunale degli Studi) in Milan. At the same time, on 24 November 1765, under the chairmanship of Count Karl Joseph Firmian (* 1718; † 1782, Milan), they established the *Deputazione degli Studi per il riordino degli studi superiori*, whose members included later vice-presidente del Consiglio di Governo della Lombardia Austriaca the physician Niccolò Pecci, the historian Michele Daverio, Giuseppe Pecis (1716 Milan–1799 Cinisello) and Milan professor of medicine reformer of female obstetric Giuseppe Cicognini. Under their authority were both the Pavia University and the Milanese Scuole Palatine, which had four Chairs of Civilian Institutions, Rhetoric, Greek and Mathematics. They also had a chair for philosophy with chemistry and since 1753 for urban and provincial law. Carli also took over the duties of Regio Ducal Magistrato camerale. He therefore created a plan for the study of engineers based on modern vacuum techniques of steam engines and the reform of Italian public schools, of course all those under the Habsburg administration. On 10 September 1767, Carli was appointed the emperor's personal adviser in Vienna. From June 1764 until May 1766, Pietro Verri, together with his brother Alessandro Verri and Marquis Cesare Beccario in Milan at the office of P. Pizzolato published the famous magazine Il Caffè: o sia, Brevi e varj discorsi già distribuiti in fogli periodici. In Il Caffè, they also published the articles contributed by Baillou, and Bošković under the title Estratto del Trattato astronomico del sig. de La Lande on 1. 4. 1765 in folio (number) 31 (Bošković, 1765 344-349)[1789] Gian Rinaldo Carli wrote Sulla Patria degli Italiani and Giuseppe Colpani also published there. In 1766 Paolo Frisi published in Il Caffè his sufficiently modern essay on Galileo's theory of tides *Saggio sul Galileo and Degl'influssi lunari*.[1790] The philosopher-jurist Cesare Beccaria published in the journal Il Caffè the foundations of the mathematical political economy with the *Tentativo analytico su i contrabbandi* (Beccaria, 1764/1766, 173-175).[1791] The basic and advanced mathematics were taught

[1789] Gian Rinaldo Carli wrote Sulla Patria degli Italiani and Giuseppe Colpani also published there.

[1790] Bošković, 344-349; Frisi, 1765/66, 2: 27-44, 291-195.

[1791] The teachers of the Milanese Palatine School were still strongly inclined to theology, despite the three engineering chairs, among which one was led by the Barnabite monk Paolo Frisi with his lectures on mechanics, hydraulics and architecture began in 1763.

by the Jesuits Francesco Luini (Luino, * 1740; † 1792) and Bošković from the Breda Observatory. D'Alembert and Diderot's friend Frisi was a strong anti-clerical recruiter in serious disputes with the Jesuits. In 1767, the bishop Carlo Battista Barletti (* 1735, Roccage in Allessandria province; † 1800) arrived in Milan; with Carli's support he excelled by his experiments with electricity in favor of Beccaria and Franklin.[1792] The Giunta degli Studi asked for amendments, among which Carli and son of Luigi Giusti, Pietro Paolo Giusti, collected the best ideas for the reform of the Faculty of Philosophy in the form of comments in 1767 and 1768. Both agreed that the physics of cosmological systems of the Franciscan professor Felice Marzari in Pavia should cease as it was obsolete; Marzari still insisted on Euclid and Aristotle and not on modern vacuum techniques. Marzari was probably a relative of a younger Natural historian Giovanni Battista Marzari (1755-1827).

Carli and Giusti focused their proposals on both Milan and Pavia schools and to the provincial gymnasiums, but they were not yet able to determine the real significance of physics lessons. According to Carli, cosmology should be taught as a history of science and no more as a prelude to many possible explanations of the structure of the world; the existence and essence of Aristotle's bodies should be replaced by modern mechanics.

In his proposals on 30 January 1767 and on July 21, 1770, Carli wanted to change only part of the mathematics-related studies based on his mathematical and engineering experiences of Padua. Pure mathematics should contain algebra and infinitesimal calculus; followed by a hydraulic engine data for civil engineers. The applied mathematics must use an infinitesimal calculus in astronomy and cartography, whereupon the lecture would be about the architecture and military machines. To the pure and applied medieval mathematics Carli added its third part containing Newton's physics lessons. Carli defended Newton's definition of mechanics, including the laws of motion and gravity, or questions about light, fire, and sound that were at the edge of the then research possibilities and only weakly verified by experiments. Carli's ideal professor of experimental or circus-oriented physics with attractive vacuum experiments was supposed to coordinate his lessons under supervision of the professor of pure mathematics on a weekly basis: experiments were still more eye-catching exhibitions than a regular part of the lesson at that time. Carli's Newtonian philosophy of nature was still a part of general physics about the structure of matter while in the particular-experimental part of physics Carli noted all about the substances of heat, electricity, or light. Giusti even more furiously criticized Marzari's outdated science and represented a more medical reforming compared to Carli's engineering. Carli avoided separation of the physics of the inanimate world from natural science and chemistry, while Giusti incorporated into physics the physiology of the human body for the teaching of doctors. Carli's mode of teaching prevailed in France and Piedmont, while in Lombardy the medical tradition was at least equally strong and there were no domestic military-mathematical experienced teachers who could promote Carli's Newtonian vacuum novelties.

In 1771 in Florence Carli published his Nuovo Metodo per le scuole pubbliche d'Italia. He proposed the teachings of mathematics and geometry at Lyceum, lectures of astronomy at the academy, the curses of general and experimental-vacuum physics at universities, including the lectures of botany and medicine without specialization in mathematics.[1793] In the reprint from 1774 in Lucca Carli tried to repair the vacancies within the higher education that occurred when the Jesuits were abolished in the previous year.

15.5.6 Carli and Bošković

Carli's work on both sides of the Venetian-Habsburg border shows us a respectable enlightener guy who was openly accepted by the rulers of both sides of the border of Venetian Serenissima or Habsburgian eagle. Carli was not just an enthusiastic supporter of Newton; his approval was also welcomed by contemporary followers of Newton's thought, such as the American Freemason Benjamin Franklin, and to a much lesser extent Franklin's friend, Croatian Jesuit Ruđer Bošković, who, as a former Jesuit, did not fit in with Carl's novelties. Probably through

[1793] Brambilla, 2000, 67; Brambilla, 1987, 346; Stancovich, 1829, 365–366; Carli, 1784-1794Delle opere, Tomo XVII.

the Carli's academic library of Koper, Bošković's astronomical work came to the library of the Koper collegium of noblemen. Shortly before Carli's appointment in Milan, on 30 April 1763, Ruđer Bošković was elected as head of the mathematical department of the University of Habsburg Pavia. The successful transition of Bošković from the Papal Rome to the Habsburg Pavia was of utmost importance for physics and vacuum technology in the Habsburg hereditary countries, which adapted to Bošković's science hourly. Immediately upon his appearance as the professor at the University of Pavia under the Habsburg administration, Bošković recommended the purchase of books of Belidor, Wolff, Lacaille and Jacquier, which the Jesuits of Ljubljana also had. In 1645, Riccioli and Grimaldi unequivocally measured the distance between Modena and Bologna; Bošković nevertheless appreciated the Jesuit Riccioli's books and in 1764 commissioned the purchase of his works for the University of Pavia.[1794]

Carli was the fan of Bošković's friend Franklin, the pioneer of electricity research. That is why Carli wrote the letter in the foreword to the Italian reprint of his Letters of Americans from 1781 to the Freemason Benjamin Franklin, and all Carli's collection of letters was printed by another Freemason, Lorenzo Manini of Cremona. The first unpaged letter on six pages was addressed to Franklin, followed by the introduction of the historian-archaeologist Camaldolese monk of Hermitic-Benedictine provenience Isidor Blanchi (1733 Cremona-1807). Carli mentioned the famous Parisian scholars the Ecuador meridian measurer Charles Marie de La Condamine (1701-1774) and Count Buffon. Carli knew the confusions about the famous Parisian academician Count Buffon data regarding the age of the Earth; Franklin worked closely with Buffon's fraction of Parisian Academy at various commissions of the Parisian Academy, including the refusal of the Mesmer's Science. Carli read American travelogues of Italian and other writers before he wrote his American letters.[1795]

15.5.7 Carli's Books

In 1757, after inheriting his father's wealth, Carli In 1757, after inheriting his father's wealth, Carli got a house in Koper and a nearby property in Cerej (Carlisburg, Žburga). His heritage prompted him to set up his own company through the wealthy legacy of his wife, Paola Rubbi (* 1724; † 1749), who died after two years of their marriage. The sad widower Carli added the family name Rubbi to his own. In 1761, with large hopes he opened the Koper spinning mill. Unfortunately, in business, too many followed the fashion principles that did not pay special attention in the real economy. A lot of noblemen in Koper participated in Carli's company, because he worked with a lot of energy and exported his products through the port of Trieste even to the Netherlands,[1796] whose Catholic parts within the limits of today's Belgium and Luxembourg has been under the Habsburg Administration already for half a century.

They did not only successfully develop spinning mills in Venetia of that time, but also in the neighboring Habsburg lands of Carniola or Styria; they were closely associated with spinning schools, which, according to the Habsburg patent from the end of 1765, enabled the exploitation of a cheap teenaged labor force. Carli certainly knew that interesting way to socialize education and business, but this time his luck turned his back just in front of his domestic Koper threshold. In 1764, Carli decided to sell his own already completely impoverished factory to neighboring company of Francesco de'Mori and associates in an emergency. In sales, the poor Carli lost 640,000 lire in 1770 according to the amount he initially put into the start of the new company. The accident was also a lucky one, since he turned from the entrepreneur to a scientist again. Under the auspices of the Academy of Revivals in Koper, Gian Rinaldo Carli and Girolamo Gravisi opened a library for Koper erudite in 1760. By their mutual correspondence we learn how both Koper native scholars personally took care of the management of the book collection, which was one of the first public libraries in the today's Slovene territory, established over half of a century after the Library of the Academy of Operosorum in Ljubljana. Carli worked in the academy between 1757 and 1760, with the help of his brother Girolamo Carli,

[1796] Darovec, 2004, 144, 148, 150.

Table 15-2: Significant scientists whom Carli quoted in his American letters in 1781

Name	Year of publication, title of the book, place of publication	Page of Carli's quote
Pater José de Acosta (* 1540; SJ; † 1600)		245
Francesco Algarotti	1737, *Newtonismo per le dame*; (1764–1765. *Opere*. Livorno: Catellini (NUK-2148)	(Carli, Albònico, 1988, 60)

Girolamo Gravisi and Giuseppe Gravisi; Gravisi's family later contributed greatly to the purchase of vacuum teaching aids for gymnasium in Koper. When the Koper Academy of Risorti was dissolved after fruitful work between 1646 and 1807, its library went to the Collegio dei Nobili of the Piarists in Koper, as Carli wanted in his time. Today there is still a large part of their books in the protection of modern Koper gymnasium with the Italian language of learning, which is named after Carli. Carli and his colleagues collected about 6,000 volumes,[1798] including Carli's Paper on Magnetic Declination (1747) and numerous descriptions of vacuum techniques.

15.5.8 Conclusion

Gian Rinaldo Carli belongs among the most established scholar of his era. He used Newton's work, printed in his boyish years, and in the Lombardy school reform he successfully advocated Newtonian physics, vacuum techniques and modern mathematics with an infinitesimal calculus. Despite rejecting Jesuitical curricula in mathematics classes, Carli co-operated with Bošković's friend Franklin, as Franklin's new American world freely attracted him. Indeed, Carli's natural historian's works were limited to his early age, but at the same time they corresponded to the extremely fruitful spirit of the then enlightenment.

The grammar school Gian Rinaldo Carli in Koper changed many names in four centuries of development. Pedagogical successes and the physics-astronomical skills of Carli brushed as the appropriate name of Koper school, and, ultimately, due to the great visibility of the gymnasium museum, especially the Museo Scolastico vacuum tools; it may even store some device that served the student Carli three centuries ago.

15.6 Ljubljana Teaching Aids Upon the Suppression of the Jesuit Society

Carli grew up in the areas of today's Slovenia to establish his plans in the cosmopolitan Milan; while many Carniolan guys travelled even further. The exceptional efficiency of Carniola-related missionaries in China was the fruit of their formidable skills, developed in domestic laboratories equipped with vacuum devices. Many circumstances have contributed to the funny facts that for the earliest period of the Ljubljana teaching of vacuum techniques we have more data on used experimental devices than on textbooks. On the other hand, many books can still be found today, while there are much more problems with the old devices for the vacuum experiments, although it would be fine to find the Ljubljana Vacuum Pump, now in the honorable age of the half of millennia. If the ancient vacuum devices may still be available today, it is extremely difficult to prove how old they should be.

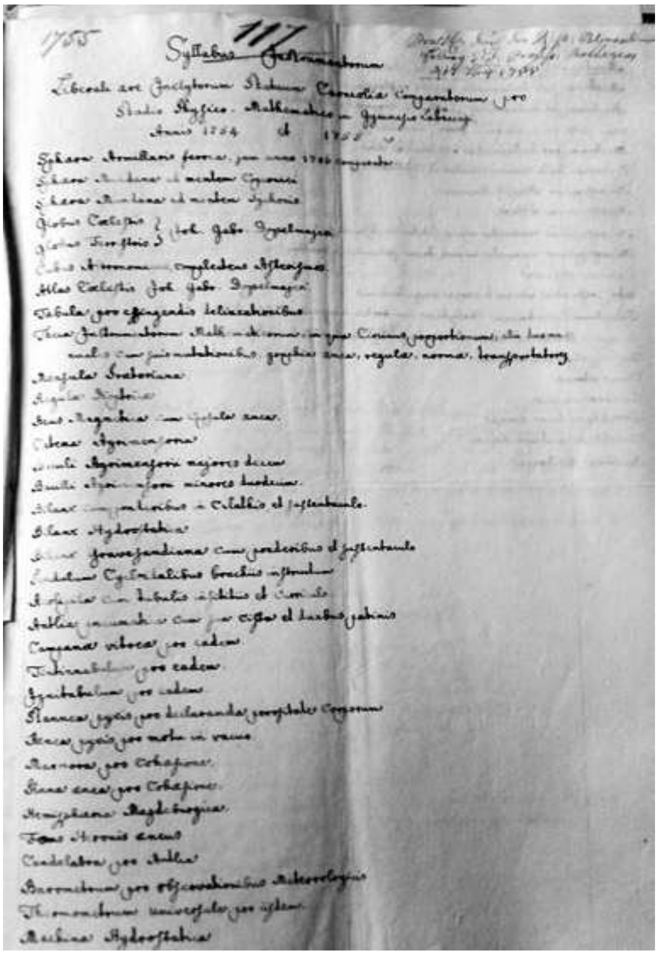

Figure 15-29: Bernard Ferdinand Erberg's inventory of the year 1755 made for the Jesuits of Ljubljana, which finally eliminated the long-standing pressure of Empress Maria Theresa for these modern purchases. First page (Archive of the Republic of Slovenia, SI_AS 6, Representative and Chamber for Carniola in Ljubljana (1747-1763), fasc. 40, box 121, Erberg, 1755 (Photographed by the author with the permission of the Archives)).

[1798] Šorn, 1984, 113, 116–117; Schmidt, 1963, 156, 158–159; Darovec, 2004, 151; Marković, 1996, 79, 80, 82, 85, 87, 90; Žitko, 1997, 69.

The difference in the attitude of school administrators to books or vacuum devices originates on the one hand from the method of procurement: in 1755, according to the plan of the Jesuit professor Bernard Ferdinand Erberg (* 1718 Ljubljana; SJ; † 1773 Krems), he acquired fifty-four instruments at one time at a relatively high costs, while his books were mostly bought individually. On the other hand, books usually have their years of issues printed. The school librarians are also interested in dated ownership entries in them, while any kind of dating of school vacuum and other devices has never been customary noted on tools themselves: at the very least, we have just some data about their purchases in catalogs.

Figure 15-30: Bernard Ferdinand Erberg's inventory of 1755 made for the Jesuits of Ljubljana to finally fulfil the long-standing wishes of Empress Maria Theresa who ordered these modern purchases. The last page being the second page (Archives of the Republic of Slovenia, AS 6, Representative and Chamber for Carniola in Ljubljana (1747-1763), fascicle 40, box 121, I map) (Photography by the author with the permission of the Archives)).

The oldest comprehensive source for studying the teaching of physics and mathematics at the Jesuit College in Ljubljana is Erberg's Purchase List, dated on 17 September 1755. It was followed by a list of all physical facilities in Ljubljana with Ambschell's signatures from 1779 and 1785. There are also some G. Gruber's acquisitions, A. Gruber and B. Schaller's catalogues. Kersnik's catalog from 1811 is also available in Ljubljana. By comparing the censuses and other data on vacuum experimental devices, we can assess the progress and direction of the development of experimental teaching of vacuum techniques at higher schools in Ljubljana.

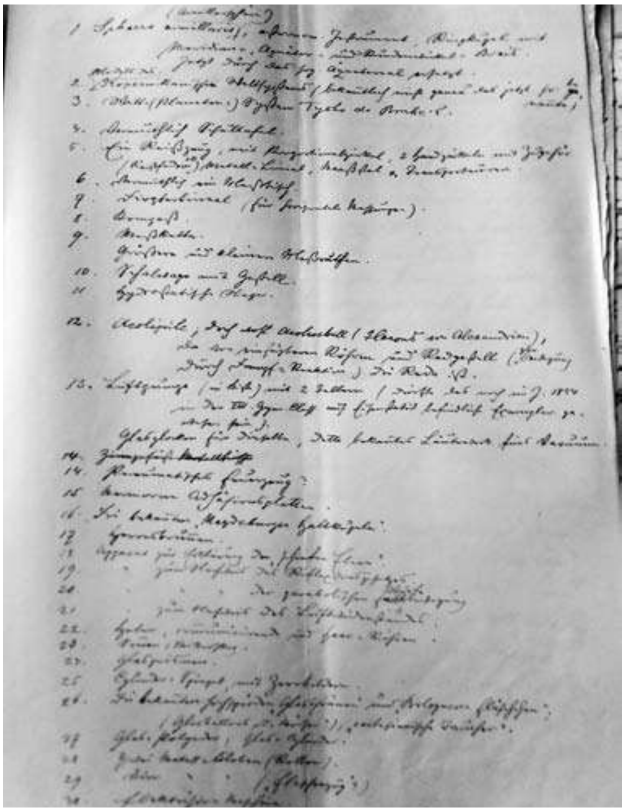

Figure 15-31: Peternel's inventory of Bernard Ferdinand Erber's devices from the year 1755 at the Ljubljana higher schools between 1850 and 1860 (Archives of the Republic of Slovenia, AS 6, Representative and Chamber for Carniola in Ljubljana (1747-1763), fasc. 40, box 121, I map, (Photography by the author with the permission of the Archives

15.6.1 Erberg

The Jesuits of Ljubljana may have hoped that they would not be forced in setting up a higher-level experimental cabinet, but that was not the case. Finally, on 17 September 1755, the baron Bernard Ferdinand Erberg compiled a list of fifty-four

unnumbered instruments for physics and mathematics studies at the Ljubljana semi-university School; a century and a half later Müllner, accidentally listed only 51 tools.[1799] In course of the vacuum experiments, this started the modern physics in Ljubljana and, of course, it is still developing there.

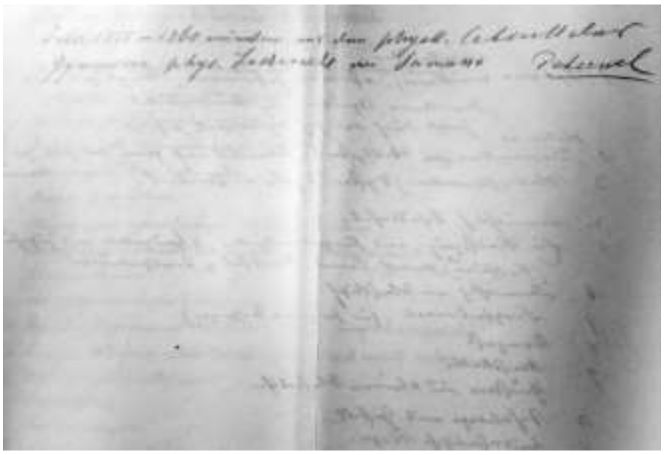

Figure 15-32: An explanation of Professor Mihael Peternel at the list of the then century old Bernard Ferdinand Erberg's devices from 1755 at Ljubljana higher schools (Archives of the Republic of Slovenia, AS 6, Representative and Chamber of Carniola in Ljubljana (1747-1763), fasc. 40, box 121, I map, (Photography by the author with the permission of the Archive))

15.6.2 *Gruber's School Tools in 1768*

On 26 October 1767, in Ljubljana at the founding general assembly, the foundation stone was laid for the Society for Agriculture and Useful Arts under the auspices of the then Provincial Governor the Count Heinrich Auersperg . On his mother's side he was a great grandson of the first vacuum vacuum researcher the Prince Janez Vajkard Auersperg. The Society was nicknamed Agricultural Society, although it was officially functioning under that name barely after the re-establishment following the Napoleon's fall. The patron of the Society was the respective provincial chief of Carniola; since 1769 the society was directly subordinate to the Provincial Governing Council. Until 1773, the first president of the Society was the councilor of the Provincial Governing Council, the commissar Josip Brigido von Brezovica (* 1736, Trieste; † 1817, Vienna). During the first two years of his term, his secretary (Schriftführer) was dr. Valentin von Modesti (1767-1769), the first permanent secretary of society (Sekretär) was Brigido's protege Hacquet from 1778 until the society lost its state support in 1787. Few months after Ž. Zois passed away, Janez Nepomuk Buset became the first president of the renewed Agricultural society in 1821.[1800]

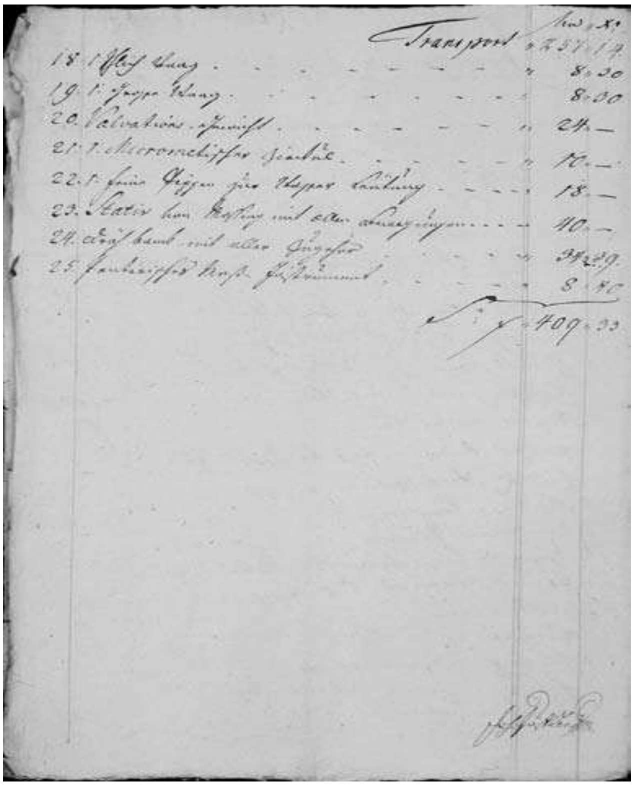

Figure 15-33: Gruber's acquisition of books and devices on August 31, 1768 (AS 33, Provincial Government, Convolute 455, Technical Unit 182) (Photographed by the author with the permission of the Archives)

An important part of the Society's activities was its support of the local secondary education, as the Society established Gruber's Chair of Mechanics in 1768, and in 1771 it established a chair for agriculture in the framework of Jesuitical philosophical studies. There Janez Nepomuk Giel taught. Gabriel Gruber was employed and probably also the first Ljubljana experimental physicist, Franc Mühlpaher (Mühllbacher, Mühlbacher, Millbacher, * 16. 10. 1744, Ljubljana; SJ 18. 10. 1760 Vienna; † 1826, Stanisławow (Ivano-Frankivsk) in today's Ukraine).

1799 Müllner, Die Realistischen, p. 171–172; Schmidt, Zgodovina, p. 303; SI_AS 6, Reprezentanca in komora za Kranjsko v Ljubljani (Chamber and representation , 1747–1763), fasc. 40, box 121, I map 17. 9. 1755.

30. universal thermometer for Meteorological observation	/	meteorology (heat)
36. Device for demonstrating air resistance	21. Device for proof of air resistance	mechanics
37. Siphon, communicating vessels and capillaries	22. Siphon, communicating vessels and capillaries	mechanics of liquids

On 20 April 1774, at a meeting of the Society Board they decided that three of society's members would travel through Carniola, collect material for the political history of the country, list the local natural resources, propose their exploitation and

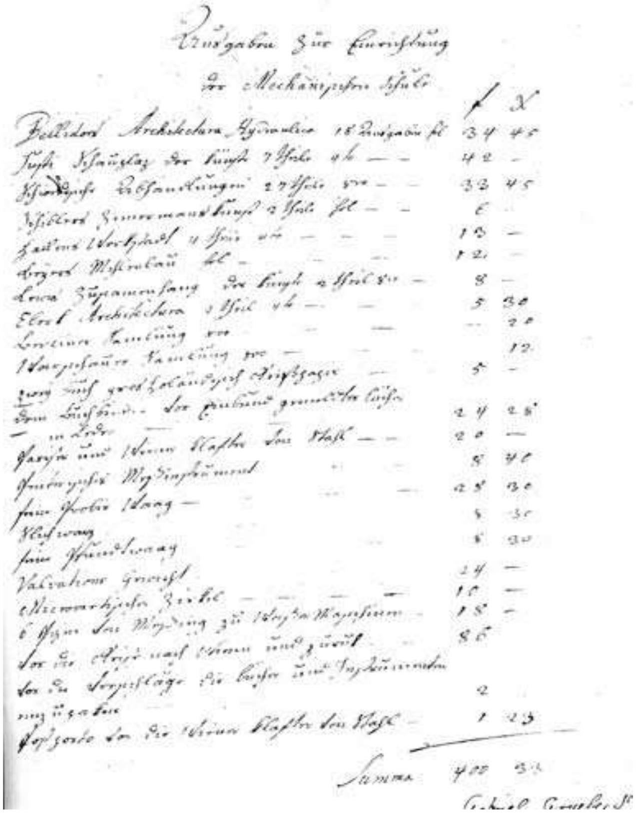

Figure 15-34: Gruber purchases of books and appliances on 28. 9. 1768 (AS 33, Regional Government, Convolute 455, Technical Unit 182) (Photographed by the author with the permission of the Archives))

multiplication. Among the three designated travelers were: Giehl, Mühlbacher and Hacquet, a member of the society since 1772;[1801] their findings were later used by Linhart. On the initiative of the Society for Agriculture and Useful Arts, the new Department of Agriculture was approved in 1771; on 7. 5. 1774 Giehl received a (renewed) permission to teach after a ban on the Jesuit society. The students of theology and philosophy did not like to attend those additional agricultural school lessons, whole the farmers, of course, did not go to Ljubljana to listen to lectures about their own craft.[1802] On 19 September 1774, at the same time with Giehl, the Carniolan agricultural society hired for the lectures about the experimental physics another former Jesuit Mühlbacher, who, however, is rarely found on subsequent lists of lyceum lecturers in Ljubljana because of the financial distress of his Ljubljana school patrons.[1803]

Table 15-4: Costs for instruction tools which Gruber proposed in the summer or autumn in 1768: »Inventory or determination of the use of books, devices, machines and models for the operation of Mechanical School of Agricultural Society established by the highest authority. Listed by the professor Gabrijel Gruber on 31 August 1768« (AS 33, Provincial government, convolute 455, technical unit 182) and again in the pamphlet on 28. 9. 1768: "Expenditure for Mechanical School Equipment" (AS 33, Provincial Government, Convolute 455, Technical Unit 182). The numbered tools listed in August are here presented as bold, and the editions of the September are in italics. In September instead of the original twenty-five expenditures for the total amount of 409 florins 33 kreuzers, Gruber proposed only twenty-three supplies for a total of 9 florins less, therefore, for only 400 florins 33 kreuzers. We list only devices that were also useful for vacuum experiments.

15. = **17**. 28 florins (fl) 30 kreuzers (kr) Precise scales for experiments
16. = **18** 8 florins (fl) 30 kreuzers (kr) Scales from lead
17. = **19** 8 fl 30 kr High precision scales for measuring with one-pound weights
18. = **20**. Comparative calibration for weights
19. = **21**. 10 fl Micrometer compass (drawing tool)
22. = *20*. 18 fl Brass faucet for water turbine
21. 86 fl Journey to Vienna and back
22. 2 fl Bookcase and tools
23. 40 fl brass stand with all the necessary equipment
13 = **25**. 8 fl 40 kr Prussian measuring devices (perhaps in conjunction with the Berlin Academy)

From 8 April 1769 to January 1785, Gabrijel Gruber was head of the Department of Drawing, Geometry, Mechanics (Engineering, Low Construction, Mapping and Special Naval Shipbuilding) and hydraulics. After Gruber's

[1801] Bufon, 1971 Naravoslovje, p. 52; Wilde, 1860 Haupttabelle, pp. 68.

departure from Ljubljana in January 1785, Gruber's pupil Jožef Marija Šemerl acted as the head of his Chair of Drawing, Geometry, Mechanics and Hydraulics. The lectures had to cease after the the emperor suspended his financial support of Carniolan Society for Agriculture and Useful Arts (Agricultural Society) in 1787.[1804] The Sunday German language lectures at the craft school were conducted by Gruber himself, and after his departure the school was taken over by Šemerl. Gruber also offered awards for the most talented students with the Carniolan Agricultural and Useful Arts Society's money. In 1787 the school was abolished because of the lack of state support inside the centralised milieu of Josephine reforms.

Table 15-5: Costs for instruction which Gruber proposed in the summer or autumn in 1768: »Inventory or determination of the use of books, devices, machines and models for conducting business from the highest point of the established Mechanical School at the Agricultural Society, composed by the professor Gabrijel Gruber on 31 August 1768« (AS 33, Provincial government, convolute 455, technical unit 182) and again in the pamphlet on 28. 9. 1768: "Expenditure for Mechanical School Equipment" (AS 33, Provincial Government, Convolute 455, Technical Unit 182). The numbered ones in August are presented as bold, and the editions of the September are in italics, when instead of the original twenty-five expenditures for the total amount of 409 florins 33 kreuzers, Gruber proposed only twenty-three supplies for a total of 9 florins less, therefore, only 400 florins 33 kreuzers. We show only devices that were also useful for vacuum experiments.

15. = **17**. 28 florins (fl) 30 kreuzers (kr) Precise scales for experiments

22. 2 fl Bookcase and tools
23. 40 fl brass stand with all the necessary equipment
13 = **25**. 8 fl 40 kr Prussian measuring devices (perhaps in conjunction with the Berlin Academy)

In addition to the Department of Mechanics and Hydraulics on the Lyceum, Gruber continued his teachings at the craft school after 1773. It seems that Erberg and Gruber sought to modernize their devices to acquire new scales, which was in the spirit of Lavoisier's progress in chemistry and vacuum techniques. Since 1755, three scales have been used on the Ljubljana College, among them s'Gravesande's and hydrostatic. Precise weighing in the Lavoisier's Parisian Laboratory made it possible to advance the technique in the coming decades.

The brass pipe for the water turbine was the ancestor of the device of the same name, which Georg von Reichenbach assembled in Augsburg in 1821. In 1770 Gruber certainly needed it also for his restoration of a hydraulic machine for lifting water from the Sava River to the water supply for the city of Kranj north of Ljubljana.[1805] The micrometer core for astronomical observations was catalogued on March 28th, 1779. It was a precision micrometer needed for astronomical of measurements whose acquisition was planned in connection with the previously printed examinations of John Baptist Pogrietschnig's students Franc Ksaver Karpe and Franz Svetic, bind to Asclepi's paper on micrometer objective lenses in Ljubljana in 1768. Gruber used that modern device for astronomical observations needed for navigation.

15.6.3 Ambschell's Devices in 1779 and 1785

It is difficult to estimate how much the fire affected the former Jesuit vacuum and other devices physical and mathematical curricula in Ljubljana in the summer of 1774. Only relatively comprehensive censuses from 1755, 1779 and 1785 are available with some intermediate footnotes and one inventory of purchases for each year between March 1781 and March 1, 1782. While Anton Ambschell (* 1751, Györ; † 1821, Bratislava) on 28 January 1779 and on 7

[1804] Serše, 2000 *Začetki obrtnega šolstva*, pp. 42.

[1805] Žontar, 1982 Zgodovina mesta Kranja, p. 206, 238, 278, 297, 454, 458.

November 1785 made brief descriptions of the seventy or sixty-six devices with notes on their utility. However, on 22 July 1779, for now unknown reasons he only noted the first

Table 15-6: Three preserved catalogs, marked italics (oblique), bold and normal.

First list of 28. 1. 1799 (*seventy devices*): "Inspection or inventory of personally audited available physical machines and devices with notes on their condition in Ljubljana on 28. 1. (1779)« with Ambschell's signature (ARS, AS 7, Regional Governance for Carniola, Rubrica Publico Politica, Litera S, Numero 19, volume 6, box 72, Acta de ann. 1778)
Second catalog of **22. 7. 1779 (thirty-five devices**), of which just before the 18th device the record of their industrywas noted as Hydrostatic: "22. July 1779, the listed physical equipment in use, as well as examples of the necessary machines, etc." (ARS, AS 7, Regional Governance for Carniola, Rubrica Publico Politica, Litera S, Numero 19, volume 6, box 72, Acta de ann. 1778)
Third list provided on 7. 11. 1785 (106 devices: 26 statics and mechanics + 19 hydrostatics-hydrodynamics + 8 gases + 7 heat + 21 optics + 13 electrics + 2 astronomy + 10 miscellaneous). It contained once Jesuitical and later acquired physical devices in the list produced on the handover of the recently dismissed Ljubljana Professor Ambschell and the representative of the Ljubljana Kreisamt (mayor's office) Galle, with the mark of the usability of devices. It is preserved in four copies, written by different hands: "The inventory of physical machines found at the physical (cabinet) in Ljubljana on 7. 11. 1785", AS 533, KKD (= Carniolan agricultural society) / Copies, Statute / 1780-1820, unpaged). Figures before the devices were taken from the appropriate census. The numbering in both censuses in 1779 is continuous, and in 1785 there was a separate numbering for each of eight branches of physics. The same devices are separated by semicolons for different censuses. Only the instruments associated with the vacuum techniques of those days are shown.

35 tools for statics, mechanics, hydrodynamics devices and aerodynamics with a vacuum technique listed on eight pages. The end of the census of July 22, 1779 did not closely follow the division into physics chapters. Any continuation of the missing descriptions of devices to show experiments related to optics, electricity, heat, astronomy and diversity has not been maintained; the supposedly lost part of the document certainly included the certificate of the responsible person, so that without complete evidence, the missing signature could be attributed to professor Ambschell only with a high probability. Therefore, the lists of individual devices and their operation of 22 July 1779 are much more extensive and detailed than other preserved material.

15.6.3.1 Devices for the Display of Static and Mechanical Phenomena

3: **Scales with weights of 10, 5, 4, 3, 2 1, ½ and ¼ pounds** (in modern measures from 5 kg to 140 g), five items for each weight; 2: lead and brass weights: 4 weights of 5 pounds, 4 pounds, 3 pounds and 2 pounds. Six weights for a pound and two pounds. Ten weights per quarter of pound and two weights per eighth part of pound.

1: *Libra with two large and small bowls, medium well received, good*. November 7, 1785: 3: Another large scale with two large and two small attachments, bad.

4. Weight for 1 pound in the form of a truncated cone; 4: Single pound insert, broken

5. **Small weights for the ounce (28.35 g), half ounce, gran (0.82 g) and their parts required in hydrostatics and in air-related experiments**

5: Small balance with bell and 5 lead weights, conditionally useful

2: **Sensitive balance for experiments**. 6: ... with a brass attachment and a wooden scraper, good

8. **Simple movable and stationary wheels with clamps for propelling multiple saw blades and other devices**

13. Linked axles for the stampers in a mill

4.2 Hydrostatic and hydraulics experimental tools

1 Fountain with one water supply, two pipes, a large brass pipe and a large collector of 4 feet, good

2: To the above belong 3 hermetically sealed tubes ~~of~~ 5 ft long, good

3: To that (fountain) belong 4 utensils, namely: carousel, lamp, tail and snow meter, good

7: *lead model for fountain, new, good*; 4: lead model for fountain

5: The same cylinder connected to the cone along the common base, good

8: *Heron's fountain, usable, repaired*; 6: Hermes' (sic!) Fountain, good

9: *(Kircher's) flowing fountain, picked up, broken*; 7: good

10: Another well, broken; 8: Reverse siphon, good

11: *Connected vessels, assembled, broken*; 9: good

13: *Two lead (vessels), assume, good*; 18: **Two glass cylinders fitted with movable closures, one with metal;** 10: Two lead water heater, good

12: *Glass bowl or water receiver, new, good*

14: Two sealed tubes with wooden attachment on one side, picked up, good

15: Four siphons, new, good; 11: Two siphons, good

16: Six glass tubes, new, good; 12: 6 glass tubes, good

17: long glass tube, taken over, good; 13: good

18: Lead cylinder, inserted into another, lead, picked up, *good*

14: Brass cylinder in the cylinder also made of brass, by the pan, good

20. Copper water troughs, two of them smaller, on one side with soldered copper conductors along one inch, and the end is approximately 2 to 3 inches at right angles along the circle. The height of the waterbed must be 14 feet. There is a good faucet or cock on the pipe, where the water flows through the open pipe. The pipes include special threads, one larger and the other smaller, in total, there are three or four. One (attachment) is sheet metal with a brass screw under the visible tube with a length of 4 feet and a width of 1 inch, the other is 2 feet long and one inch wide; while the copper (tube) flows into the experimental space where, under the lamp, the water is separated into the constituents (probably its mineral contents, sic!) to collect a lot of such snow (resembling the snow in Hell's pump in Banská Štiavnica).

18: The metallic sheet 5 feet long and 3 feet wide device for twisting waterworks, good

19: Glowing round bell made of brass, good

4.3 Apparatus for displaying air experiments

53: *Vacuum pump that was repaired, but without a large box which does not have its own values, picked up, but not good*; 21. **An upright vacuum pump of alternating (Hauksbee's) *double*-barrelled design. Among the recipients one is small and the other is large, one with a large cock (pipe), under which we can place a barometer; 34. An elongated glass hose (actuator) 4 inches wide and 3 or more feet long, closed with a brass hood. This lid has a suitable pliers in the middle, which can be opened from the outside without moving the board for gravity experiments in a vacuum;**

35. A horizontal still unused vacuum pump, which is like Boyle's vacuum pump under the number 21.

1: (Hauksbee's) double-barrelled vacuum pump, good

22. Glass ball with a large brass cock, which must be firmly attached so that the cock can be screwed onto Boyle's vacuum pump and could exhaust the air through the valve.

23. A similar copper (ball) with a faucet designed to hold 2 or 3 polished balls.

24. Parabolic wooden arch one foot long with the thickness of 3 inches. The inner surface of the bow, which should be half or three quarter of inch wide and 3 inches long. On one side, a cone is attached which, on one side, pours out of wood, so that the sunken arc forms a cone, which appears in the mirror as the focal point of the parabolic mirror; the bow is attached to Cheredon or a tripod.

25. Cheredon or a tripod, with which the fixed arch is raised or lowered

26. Tripod for the observations from all directions, which has an exact base

27. Precise Micrometer

54: *Two Magdeburg hemispheres, good*; 2: Two large Magdeburg hemispheres, good

55: *Gas-meter (Parometer), new, good;* 3: Gas-meter without glass, good

4: Six recipients, three *s* opened at their tops and three closed

5: Another three recipients, the first with a brass tab, the other with a long open wood and a brass tab, a third without a closed brass, are connected altogether with the afore mentioned stand

30. Glass tube, open on both sideswith a diameter 3 inches, one and a half foot long; on both sides there must be two caps of brass in the glass. Each one has a brass orifice, at least 3 cubic feet long, in addition to the sharpness that is screwed onto Boyle's vacuum pump.

6: A spherical ball with a brass pipe, good

7: Copper ball

8: Two small Magdeburg hemispheres

4.4 Devices for displaying experiments with fire

56: **Désaguliers pyrometer, new, good; 1: Désaguliers' fire gauge with the 4 inches long metallic sheet and filter for water, good**

57: Two thermometers, new, good; 2: Two thermometers, one in brass, the other in a wooden box, good

15.6.3.2 Devices for Experiments with Light

32. **A glass didactic game with figures of 8 or 9 inches and a smaller length**. Here Ambschell added a note for maintenance: When purchasing machines, they are cleaned with a cloth in preparation for their first use, and we regularly monitor it carefully to ensure that the durability of used machines is best dealt with. (During holidays), we store them at least until the end of October, so that machines can reduce costs and increase durability.

15.6.3.3 Electricity Display Devices

26: Other (negatively charged) electrostatic spindle from cardboard with leaden conductors, good; 2: Other (negatively charged) electrostatic spindle with leaden conductors
27: *Old spherical electrostatic generator with conductors made of brass, picked, broken*; 3: Old circular electrostatic generator
28: Large and small amplifier with conductors made of brass, polished, broken; 4: Large amplifier made of brass
5: Three other amplifiers with screws, good
29: *Electrophorus on lead base, new, good*; 6: Electrophorus, good
30: *Other amplifier, new, good*; 7: Screw amplifier, good
31: *Two brass and one iron circuit, new, good*; 8: good
32: *Electricity translation tube, new, good*; 9: good
33: *Four bells without their clappers (for ringing under electric current), picked up, good*; 10: good
34: *Rubbing brush (friction in an electrostatic machine), new, good;* 11: good

15.6.3.4 The Author of Inventory and his Devices

On April 28, 1779, only Ambschell was signed under the record of physical devices: "In Ljubljana on January 28, Anton Ambschell, a physics teacher, I certify that all the machines listed are found in the condition together with the things found on the spot." The second part of the inventory with a possible signature of July 22, 1779 was not found. Under all the lists dated 7/11/1785, both former physics physicist Anton Ambschell and Karl Baron Gall, on behalf of the Kresia Office of Ljubljana, were signed under the transshipment inventory in Ljubljana. Only until October 20, 1785, Ambschell was a professor of physics and rector in Ljubljana, and then two years later he was a professor of physics and mechanics in Vienna, after Bishop Herberstein offered him a lecture in Ljubljana on 1 July 1783 after a ban on preaching for complaints students due to too many domestic (familiar) procedures in physics examinations according to Biwald's textbooks.[1806] The next document in the same package dealt with the books of the libraries.

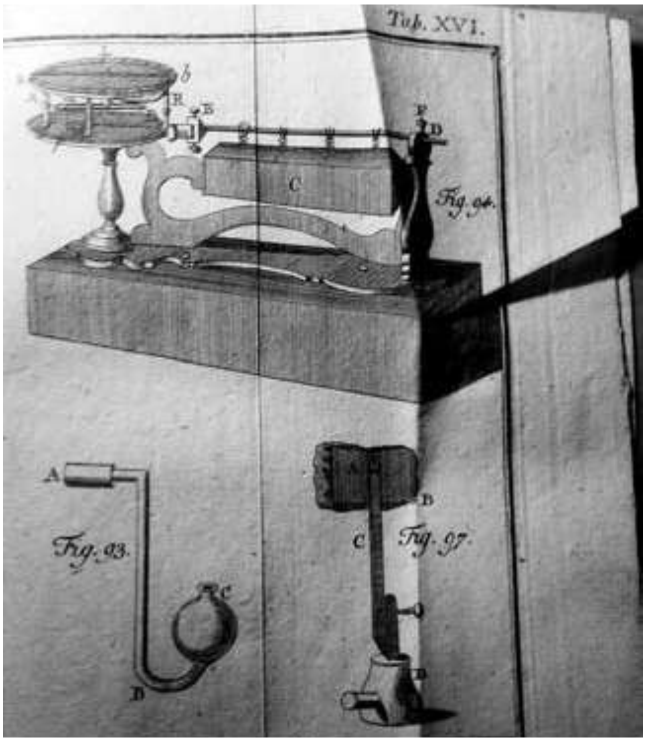

Figure 15-35: Figure 93 with the Drebbel thermometer and Figure 94 with the measurement of the expansion of heated bodies on table 16, described on pages 164 and 171, drawn at the end of the second part of Ambschell's favorite experimental manual Sigaud de la Fonda, published in 1785 (photographed by a writer in Franciscan Library in Ljubljana with the permission of Dr. Miran Špelič OFM).

Of course, the most attractive vacuum pumps were among the devices for gassing. But not just that. Prior to 1779, the residents of Ljubljana were also able to afford the gasometer (Parometer), which in

[1806] SI_AS 7, Deželno Glavarstvo, Ecclesiastica, box 212, Litera A, Numero 8, Volum 1, Ambschell Priesters Beschuldigung / wegen Verschiedener In-Briefen. Acta de annis 1782, 1783.

Table 15-7: Physical (and above all chemistry) experiments with their costs noted in the Ljubljana higher schools between March 1781 and March 1, 1782 (ARS, AS 7, Regional Governance for Carniola, Rubrica Publico Politica, Litera S, Numero 19, Volume 9, Box 73).[1807] Only the devices associated with vacuum techniques are listed.

Inventory number	Price	Name of the tool
5.	1fl 48 kr	2 pounds of yellow wax of 54 kr each
6.	27 kr	Chalk
7.	36 kr	4 pounds of rosin (residue from the distillation of turpentine oil useful for the chemical industry)
8.	5 fl 30 kr	2 ½ pounds of silver per 2 fl 12 kr each
9.	1 fl 9 kr	Smoky HNO_3
10.	48 kr	8 lots of staniol (Tin Foil) per 6 kr each
11.	42 kr	7 lot of turpentine oil
12.	5 fl 40 kr	the second tripod-stative for the mirror glass plate of the electrostatic generator, which was unnecessarily missing in the friction electric collection
13.	4 fl 30 kr	4 ½ measures of wine spirits (ethanol obtained at the distillation of wine sold in a 5-percent to 70-percent solution in the Newtonian period). 1 florins for everyone

1785 was renamed it into the air gauge. Certainly, it was an Ingenhousz or Volta's improvement of the eudiometer for the measurement of the "goodness" of the air according to the invention of Marsilio Landriani (1751; † 1815) in 1775. The f-reemason and imperial physician Jan Ingenhousz (* 1730; † 1799) was fine. In 1769 and 1789, he corresponded with B. Hacquet, who used the Ingenhousz's Eudiometer (euriometer) with sodium nitrite to investigate the cause of auto-burning in high mountains; Hacquet borrowed his school tool, but in the meantime, he also wrote to Idrija pharmacist E. Freyer, although they were not always in their best relations.[1808] The eudiometer has become particularly popular in Volta's electric gun pistol design; two eudiometers for chemical syntheses and one electric gun were also used by Janez Krstnik Kersnik (* 1783; † 1850) in 1811.[1809]

Among the experiments with heat, a pyrometer was compiled in the first place. The English freemason and the editor of the London Royal Society journal Phil. Trans. Désaguliers invented that tool to observe the shrinkage and expansion of metals in temperature changes. Nowadays, a little later invention of the modern pyrometer is attributed to the queen's potter Josiah Wedgwood (* 1730; † 1795). The associate of Birmingham's Lunar Society Wedgwood was accepted as a fellow of the Royal Society right after the publication of his discussion on the pyrometer for temperature testing in pottery baking in the once-day Désaguliers' Philosophical Transactions magazine in 1783.

15.6.3.5 Annual Purchases in 1781/82

An annual grant of the cabinet of physics was 25 florins (fl) under Jesuit guidance between 1763 and 1774. It covered 5 % of the price of the original fifty-four Erberg's orders. Thus, between 25 March 1781 and March 1, 1782, 17 of these chemicals were purchased for 17 consecutive months, with 26 fl 28 kreuzers (kr). The title of the document written on March 1, 1782 was: "A list of the usual annual expenditures of the *Estates General Superior of the State*, given for physical experiments, when this year reached 25 fl and was spent between March 1781 and March 1, 1782". 56 kr was a deficit over the previous year exceeding the 25 fl supplements used under the first item; followed by a list of new acquisitions to point 18. Among other things, they bought six times eight lots of staniol (Tin Foil) for a total of 88 kr under number 10 (the Viennese loth (lot) measured 4 quintiles or 17.5 grams, 0.56 kg = Viennese pound = 32 lots) and under number 9, the spiritum

1809 ZAL, LJU 184, The classical grammar school in Ljubljana, the technical unit 53, the 14th device on pages 8 and 10 respectively, among the devices for heat and electricity (Eudiometer) and the first device on non-aggregated pages 9 and 18 among electrical devices (Pistolletes (sic!) electriques).

nitrians, most likely HNO_3, for 1 fl 8 kr. The most expensive then purchased device for the price of 5 fl 40 kr were the devices for the operation of the electrostatic generator, recorded under number 12, as the only outstanding physical device among the prevailing chemicals. Anton Ambschell, who signed the document on 1 March 1782 in Ljubljana, was also a member of the Viennese University. The total cost of purchases in the amount of 26 guldens 28 kreuzer was confirmed by chamber bookkeeping two and a half weeks later, on March 12, 1782.

15.6.3.6 Destinies of First Physics Experimental School Devices of Ljubljana in Nineteenth Century

The professor of physic Ambschell certainly had the first the word in the purchase of new devices in 1779. It is therefore not surprising that he has thought of many vacuum devices, with which he experimented and published his findings.

In 1811, Kersnik attributed slightly different names to his experimental tools in Ljubljana also because he used French language. The most popular device in Ljubljana was an electrophorus found in the censuses from the years 1779, 1785, and 1811.[1810] During the first experiments with the ancestor of the electrophorus, Augustin Hallerstein of Ljubljana took part in experimenting in Beijing in the 1750s. On 1775 in Como Volta based his research of Beijing data before his assignment to the University of Pavia. He assembled the electrophorus. In 1833, the professor of mathematics in Slovenia, Karl Hummel, published a paper about a simple electrophorus for collecting electric charges with friction[1811] in Baumgartner and Ettingshausen's Viennese magazine; this was the first journal of mathematical science in the monarchy.

In 1833, a chemistry chair for Kersnik was founded at the Surgical-medical department of Lyceum, where Mihael Peternel (* 1808, the Laniše farm in the then parish of Nova Oselica (Neuoslitz); † 1884) later assisted him. Peternel was appointed as the teacher in 1842.[1812] In 1845 Peternel was Kersnik's chemistry assistant,[1813] but he also lectured on the Lyceum on the same subjects of chemistry; there, of course, he carefully examined the vacuum and other physical aids and records of them, and added his, still interesting notes. Between 1853 and 1861, Peternel lectured on chemistry at the lower level Real High school in Ljubljana.

The nationally aware Slovenian Peternel was a longtime professor of chemistry, natural sciences, Slovene language and physics until 1860/61. In 1850 he was also the director of the real school in Ljubljana.

In his Agricultural Chemistry published in Slovenian language, Vertovec used simple words; with them he tried to inform the ignorant reader of the mystery of chemistry, which "educated students learn for many years". From these terms and from those presented by professor Mihael Peternel in the discussion: "Names, designations and properties of chemical elements" in the reports of the Ljubljana Real school in 1862, the Slovene chemical terminology developed. Peternel investigated the impact of electrical discharges on weather conditions under the influence of lower pressures.[1814] Robida added his own terminology in his physics in 1849.

15.6.3.7 Conclusion

In course of the two and a half-century, the Ljubljana physics-mathematical cabinet, with the emphasis on modern vacuum techniques, of course got its updated among the next generations. Due to the lack of technical heritage preservation works, today's vacuum devices are difficult to find, since they were often discarded, as we still do with old bad toasters or with old washing machines. Everything that profoundly tells us about these tangible pillars of learning of the former Ljubljana-based science-oriented youth has been preserved just in some catalogs, which at least partially unravel the patina of the former days. One thing is certain: Ljubljana students, unfortunately only male, have been able to view the basic knowledge of the novelties of vacuum techniques and related sciences in the high school at home without any real delays regarding the then centers of science,

although they may not have been taught by the giant vacuumists of Boyle or Pascal's class.

15.7 Volta’s Relative and His Idrija Pharmacy: Idrija Mercury for Barometers and Thermometers (on the 275th Anniversary of Volta’s Birth)

15.7.1 Introduction

Of course, the Ljubljana vacuum devices were not the only ones in the country. For centuries Idrija was the cradle of technical achievements in Carniola. The Viennese authorities sent the most prominent experts to Idrija. They wished to improve the processes of obtaining and processing Idrija mercury ore. The most prominent leaders of the Idrija mine were Abondio Inzaghi and his great grandson; the latter primarily because of his close relationship with Alessandro Volta.

15.7.2 Abondio Inzaghi and Torricelli

Abundus Maria Inzaghi (Abondio, Abbondio, * Como; † 1691, Graz) was the Councilor of the court chamber and the senior mining supervisor in Idrija under the emperors Ferdinand III and Leopold I and their first minister the prince-vacuumist Janez Vajkard Auersperg. Like the Ptuj based brothers Caccia, he initially dealt with the sale of cloth and moneymaking; Later he moved to Graz, where he became head of the monetary office. He reorganized the production of mercury in Idrija and then controlled the trade of mercury, copper and similar goods.[1815]

Abondio was established in Carniola in parallel with the relative of Galileo Galilei, Roberto Galilei (* 1615, Florence; † 1681, Ljubljana) in the shadow of the mighty Auersperg. While Abondio settled in Graz and Idrija, Roberto led his banking and political affairs from a rented house near the Šuštar (Carpenter) Bridge in Ljubljana, at least after the birth of his oldest son, Bartolome Engelbert Galilei, baptized in the Ljubljana Cathedral on February 11, 1648. According to Robert's perhaps slightly altered claims, Roberto Galilei should have been working in Carniola as early as 1632. At the beginning of Abondio's and Roberto's work in Carniola, the scientific successor of G. Galileo, Evangelista Torricelli (* 1608; † 1647), set up the first vacuum experiment including the Viviani’s initiative with Idrija mercury thermometer in 1643. At the end of 1644, he informed about his success the Parisian monk Marin Mersenne, who was the main distributor of scientific ideas in the then Europe; Mersenne soon became acquainted with Blaise Pascal's novelties. In 1646 Pascal publicly repeated the experiment, and in 1668 he sent his brother-on-law into the hills with a huge mercury barometer, full of Idrija ore. With this, the mercury barometer also became a tool for determining heights. Ten years after Torricelli's beginnings, Otto Guericke developed experiments with a vacuum pump at the initiative of Prince Janez Vajkard Turjaški (Auersperg) in 1654. Using a mercury barometer, Guericke, as mayor of the city of Magdeburg, successfully predicted the upcoming storm, and earned the electoral votes of his fellow citizens and, above all, the sympathies of Magdeburg housewives even if they were not allowed to vote directly.

The imperial deputy for Financial and Military Issues Karl Gottfried, Count Breuner (Brenner), appointed Abondio as the chief inspector of the Idrija mine. With the acquisitions of the manors north of Graz, Abondio joined the Styrian Estates general on 19 August 1658. Abondio Inzaghi introduced the state management and sale of Idrija ore in 1659. He accelerated the export of Idrija mercury through the Amsterdam firm of Johann Deutz (Jean, * 29. 11. 1618; † 1673), a German native of the city of Cologne. The Emperor Leopold raised Abondio into the rank of baron and then into the rank of the count. However, the luck sunk down and soon it began to rummage that Abondio has more profit from the sale of mercury than the state treasury itself.[1816] On 12 December 1667, he was suspended after a scandalous two-year process, like the modern processes in Slovenia. On 3 December 1669, Abondio was finally discharged from the Idrija mine. Even Abondio’s nephew Benedetto Odescalchi (* 1611) was unable to help. In 1674 Benedetto Odescalchi (* 1611 (Como) put the foundation stone of the church next to Abondio's Castle Oberkindberg; he was assisted by Benedetto, although Benedetto two years later became Pope Innocent XI The

investigation against Abondio was led by Wenzel Franc Lobkowitz (Wencel Evzebius, * 20. 1 1609, Prague; † 22 April 1677, Ravdnitz (Roudnitz, Rudnice) near Laba in the district of Letimeritz / Litomerice) who became the mayordomo in 1664. Lobkowitz simultaneously displaced from the Viennese court the first important Carniolan vacuum researcher, Janez Vajkard, Prince of Auersperg. As Auersperg bought a lot of manors near Idrija and had a lot of diplomatic friends in Amsterdam, he knew Abondio very well and their downfalls were certainly related. That was a time of great friction at the Zrinski-Frankopan's conspiracy, which ended with the decapitations of Croatian and Hungarian nobles in the spring of 1671.

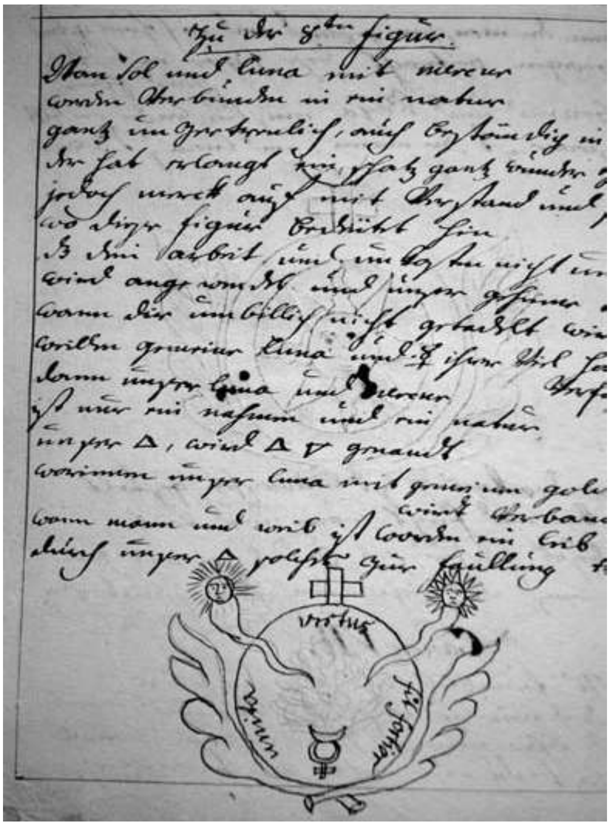

Figure 15-36: Freyer's doubled Sun shining on the fountain spring in Freyer's abundantly illustrated student copy of the book JC Vanderbeeg Das geheime Buch der Weisheit Zur Langen Leben und Vollkommenen Reichtum (1739) (SI_AS 863, p.1)

The only real rival of Idrija mercury was the Spanish mine Almadén, where in 1645 the state also withdrew powers from the powerful bankers Fugger so that the state could take over the administration itself. Early enthusiasm for mercury vacuum barometers greatly contributed to the increased demand for Idrija mercury; although the use of mercury was quantitatively small in barometers compared to the needs for amalgams for the cleaning of silver ore, it was scientifically prestigious to use mercury. As always, an exceptional prestige brings glory and sales. Scientific use of mercury, of course, did not begin with vacuum barometers, because the mercury was all the time a fundamental element of alchemical

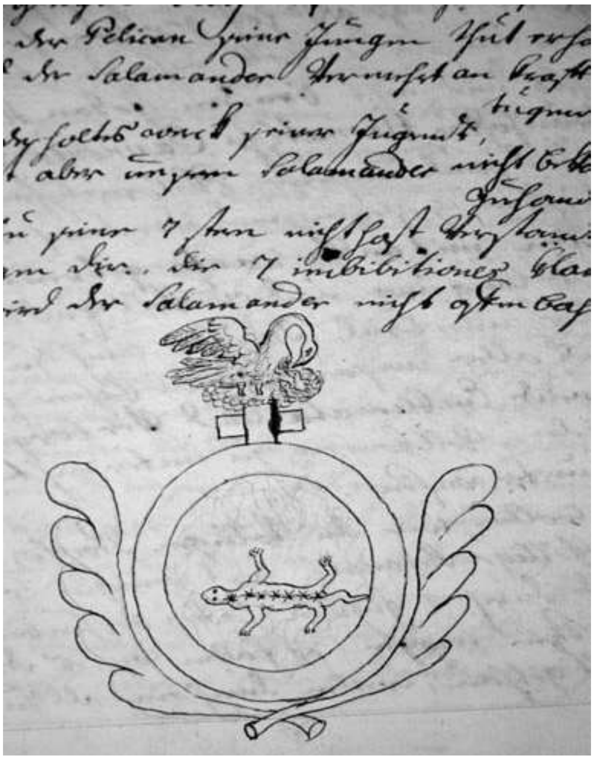

Figure 15-37: Swan above the salamander in Freyer's abundantly illustrated student the copy of JC Vanderbeeg's book Das geheime Buch der Weisheit zur Langen Leben und Vollkommenen Reichtum (1739) (SI_AS 863, p. 1)

transmutations, which were also taken by crowned heads from Emperor Rudolf II (* 1552; † 1612) all the way to Leopold I. The alchemists used vacuum techniques to distill their secrets mostly with fractional vacuum distillation, probably found by the Greek alchemist Padanius Discorides (* about 40; † 90). He was the military surgeon of the strange emperor Nero; he noticed a condensed substance on a lid of a vessel in which he heated mercury in Rome. The fractionation distillation techniques at reduced pressures were then developed by others in pharmacists' alchemy. In Idrija, basically the founder of the pharmacy was a Bohemian chemist Ernest Freyer, the beginner of the most important dynasty of Slovene pharmacists, with his son Karl and his grandson Henrik Feyer.

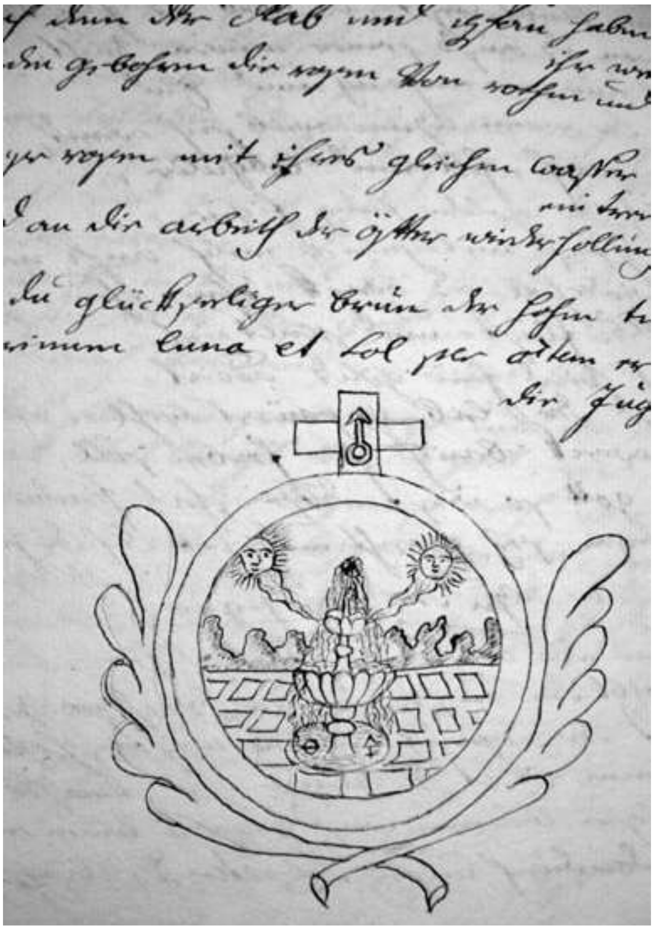

Figure 15-38: Freyer's Sun, sown on the fountain spring in Freyer's abundantly illustrated student copy of the book JC Vanderbeeg Das geheime Buch der Weisheit Zur Langen Leben und Vollkommenen Reichtum (1739) (SI_AS 863, p.1)

Freyer learned vacuum distillations at home at Žatec, the base of the producing of good beer. Between 1751 and 1753, he learned pharmacy skills in the Ljubljana pharmacy of Franz Karl von Weinhardt (Weikhard, Weykhard, * 1703; † 12. 6. 1768, Ljubljana) on Novi trg no. 2 (today Jurčič Square No. 2) who bought the house in 1740. Weinhardt supplied Idrija with vacuum-distilled medicines at Freyer's help during the epidemic of the pagan in 1752. Weinhardt was also successful in the business, since on 14 February 1754, he sued in Ljubljana even the famous sculptor Francesco Robba (* 1698; † 1757) for unpaid medication in the amount of 41 guldens and 33 kreuzers with 6% interest.[1817] Franc Karl Weinhardt also had a house in Čevljarska Street no. 2. He led his pharmacy on today's Jurčič Square no. 2 until 1665, when his son from his marriage with Marija Klara, the doctor Karl Avguštin Weykard (* 24 August 1736, Ljubljana) took over the pharmacy until 1785. Then until September 21, 1844, pharmacist Jožef Filip (Philipp) was the owner of the house.[1818]

Figure 15-39: The title page of JC Vanderbeeg's masterpiece from which Freyer copied and transcribed

Weinhardt's pharmacy had a centuries-old tradition and high-quality vacuum distillation equipment in Ljubljana for production of extracts of medicines. In the southern part of the pharmacy on today's Jurčič square no. 2 a pharmacist Valentin Cirian(i) and his wife Lukrecia worked between 1622 and 1629. From 1652/53 to 1661, the pharmacy was developed by pharmacist Ludovik Hauenstein (Hauenstain) together with his heirs until 1672; he was followed by the doctor of the Irish genus Janez Juri Tosch until 1694, and then by his descendants until 1705. Then the pharmacy was purchased by the pharmacist Janez Peter Sartori and his wife Ana Eleonora, who bought the neighboring northern house of Karl von Samburg (Sameburg) in 1717/18. Both buildings were merged into a single large pharmacy, if their successor Weinhardt did not do the job in 1752. The Northern House also had a pharmacy tradition, since it was operated by pharmacist Vincenc de Agnelatti from

1817 R. Andrejka, Zgodovina kramarskih hišic v Prešernovi ulici, *Kronika*, 1938, *5/1*, 19.

1818 Fabjančič, 1940 Ljubljanski Frankoviči v 16. in 17. stoletju (nadaljevanje). *Kronika*, 1940, *7/2*, 142–150 and 206–214, here pp. 149, 213; Ludwig Schiviz von Schivizhoffen, *Der Adel in der Herzogthum Krain*. Graz, 1905, 76, 202.

17 March 1588 until 1618, followed by his heirs Janez, Jeronim, Vincenc and others until 1645.

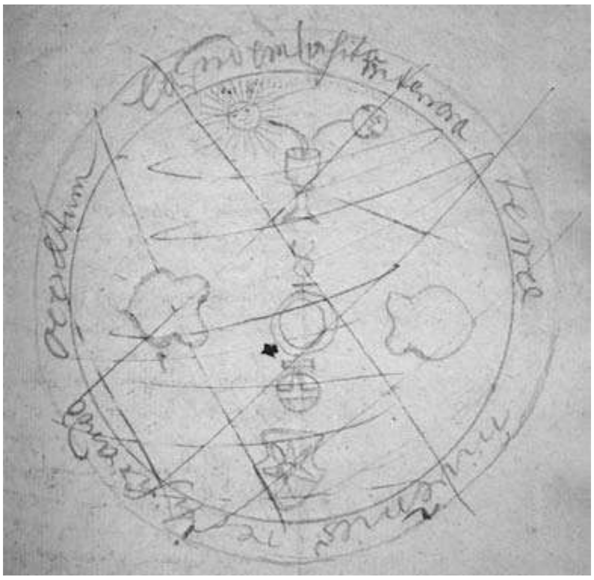

Figure 15-40: Freyer's symbolic sketch of distillation procedures in his manuscript book, dated 1751 in Ljubljana, entitled Curiosity (Curiositam cujus generis seu curiosa na(tur)ae miracula (SI_AS 863 Freyer's legacy box 1).

The pharmacist Janez Peter Sartori and his wife, Ana Eleonora, had several children in Ljubljana. On July 18, 1714, one of their godfathers was Adam von Pettenegkh Pöttickh (* 1640/1645; † 1705). Adam von Pettenegkh Pöttickh was a son of R. Galilei's Ljubljana host John Baptist Petek. Adam von Pettenegkh Pöttickh served as the caretaker of the Military Krajina. On 26 June 1715, he chose his wife, Marija Ana Pettenegkh born Wisethal.[1819] Adam Pettenegkh had a large library of works on medicine, pharmacy, and chemistry, also a silver compass[1820] which was an analog computer, created in the Galileo Galilei's workshop.

Franz Karl Weinhardt took his pharmacy from Ljubljana pharmacist Janez Peter Sartori, a relative of Inzaghi's predecessor on the head of the Idrija mine, Anton Sartori. Sartori took over the Idrija mine in 1754; because he urgently needed a pharmacist, his acquaintance Franc Karl Weinhardt recommended his student Ernest Freyer. With Freyer's arrival, the vacuum distillation procedures became the constant of the Idrija mine. When Anton Sartori died suddenly at the end of 1764, the new Idrija director, Inzaghi, of course inherited Sartori's pharmacist Freyer.

Figure 15-41: Freyer's transcript of Snyder's work, in which the description of a large mercury vacuum barometer was kept under the pen of Ernest's son and assistant Charles Freyer following the letter from the Lithopolitan Academy of Sciences (Swiss Stein am Rhein or Petersburg) mailed in 1787 (Johan Monte Snyder, Universae Medicinae (ed. Berlich), Götz, Frankfurt, Leipzig, 1678. Bind to Joannes de Monte Snyders (Snyder, about 1625-1670), Metamorphosis planetarum: dass ist, Eine wunderbahrliche Veränderung der Planeten, and Metallische Gestalten in ihr erstes Wesen ... (ed. Berlich), Tobias Oehrling, Frankfurt, 1684 (first edition 1663) (SI_AS 863, box 2))

When he took over the administration of the Idrija mine, Franc Janez Count Inzaghi (* 1734; † 1818) developed the perspectives of the use of Idrija mercury for scientific purposes. He was a second cousin of the mother of Alessandro Volta, who, after the ban of the Jesuits, taught in Como (1774) and then in Pavia (1778/79) along with Scopoli. Both cities were then in the same Habsburg state together with Carniola; sharing their same Habsburgian fatherland enabled the rapid acquisition of Volta's inventions in Ljubljana and Idrija and the hourly dispatch of Idrija mercury for barometers and other vacuum devices to the Volta's Laboratory. Volta's father had been a Jesuit for some time, and A. Volta also used the Jesuitical suits during his studies in Jesuitical school. Inzaghi also worked closely with the Jesuits of Ljubljana; he financially supported the publication of Škofja Loka native Martin Prenner's exam theses with the Jesuit professor of physics, Gregor Schöttl. The theses were based on Bošković's science of vacuum and atoms, which was also admired by

[1819] Ivan Vrhovec, Zgodovina šentpetrske fare v Ljubljani, 1903, p. 43; Schiviz, 1905, 43, 51, 55.
[1820] SI_AS 309, Pettenegkh, 23. 1. 1705, fasc. 35, box 85, litera P, pp. 18–31, 100–104.

Volta. They were printed in 1769 in Ljubljana together with a book on the chemical background of the phosphorescence of the Torino professor of experimental physics with chemistry since 1747, Bošković's friend the Piarist Giambattista Beccaria.

Figure 15-42: A writer of these lines during his lecture on Bošković and Volta in formerly Volta's lecture room at the University of Pavia on September 10, 2011

Soon after his invention in the spring of 1777 Volta sent his last publications about the combustible air and his vacuum related invention of pistol and eudiometer to the emperor's brother, Prince Karl of Lorraine. Karl loved the electrical ecperiments as an enthusiastic Bošković friend. Karl's confessor in Brussels was A. Hallerstein's brother, the Jesuit of Carniola Janez Vajkard Hallerstein.[1821] Of course, Karl and Count Kobencl in Brussels were arguing all the time, while the clever polite Bošković knew how to befriend both of those clever guys.

Volta's mother, Mary Maddalena, and the Idrija manager, Franc Janez Inzaghi, were the second cousins and despite the distances they maintained their close contact. Thus, at the end of August 1794 Volta invited Inzaghi in Graz to his wedding without knowing about the death of Franz Anton Inzaghi (* 1719; † 1791), the elder brother of the former Idrija administrator Franc Janez Inzaghi.

On January 10, 1794, Franc Janez Inzaghi congratulated Volta on his brunette bride from Como, Maria Teresa Peregrini.[1822] They married less than two weeks later so that Volta could forget his prolonged affair with the promising Parisian actress.

Figure 15-43: A writer of these lines during coffee-break with Italian scholars after a lecture on Bošković and Volta in front of the rectorate of the University of Pavia on September 9, 2011

Figure 15-44: Volta's pistol, stored today at the university in Pavia.

Franc Janez Inzaghi led the production of Idrija mercury at a time when Volta used mercury in barometers for his experiments with gases, especially in his "physical theater" of the Habsburg University in Pavia, where he joined two years previously employed Scopoli in 1779. Scopoli's and Inzaghi's associations with Idrija naturally smothered supply of mercury for pioneering scientists. In 1784, Volta visited Vienna, and the Habsburg authorities gave him an important amount of Idrija mercury for experiments in the "physical theater", which was roughly completed

[1821] G. Pancaldi, *Volta: Science and Culture in the age of Enlightenment*, 2005, 29, 105, 152, 155; R. W. Home, Volta's English Connection. *Nuova Voltiana*, 2000, *1*, 128–129.

[1822] A.Volta, *Epistolario 1788-1800* (ed. F. Massardi), Bologna, 1952, *3*, 224.

in 1788. In 1790 and 1791, Antonio Cetti (* 1752; † 1835) spent several weeks manufacturing Volta's thermometers, barometers and similar devices filled with Idrija mercury in Pavia. The priest Angelo Bellani (* 1776, Monza; † 1852, Milan) later added others.[1823]

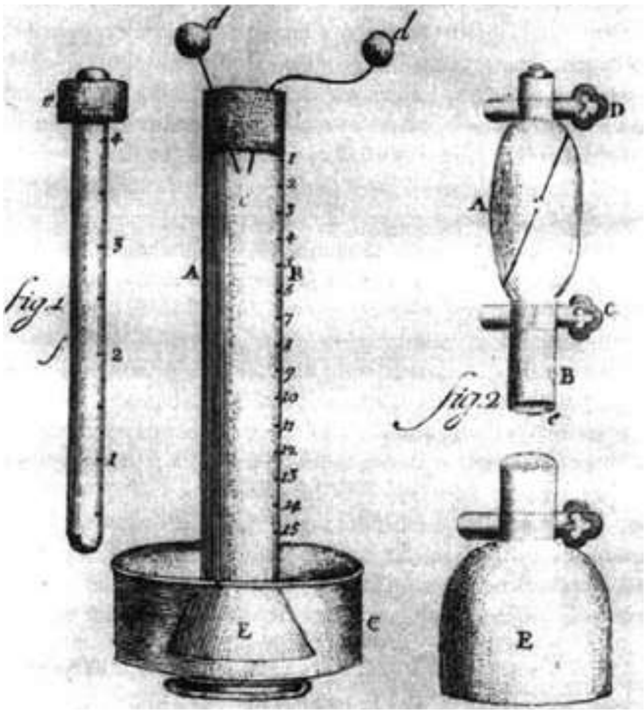

Figure 15-45: Volta's eudiometer, kept today at the University of Pavia

The members of family Inzaghi were highly educated; their technical talent was also inherited by Alessandro Volta (* 1745) by his mother Maria Maddalena Inzaghi, cousin of Idrija manager Franc Janez Nepomuk Inzaghi. In Graz Inzaghi gathered a well equipped library where they wrote their own ideas in their books. Among others, they had the first edition of Valvasor's Glory and Topography, Experimenta nova (1672) of O. Guericke in a joint binding with Coelum Sephiroticum Hebraeorum of J. Chr. Steeba (1679), China of A. Kircher (1771 with Inzaghi's marginal notes and proprietary enrollment), Kircher's Mundus Subterraneus (Inzaghi had edition of 1678) and Magnes sive de Arte Magnetica (1654, with Inzaghi's bookplate).[1824] For Inzaghi's concept of vacuum, Otto von Guericke's book was of the utmost importance with its invention of the vacuum pump and the first meteorological forecasts using a barometer full of Idrija mercury. Similarly, Kircher's not deeply scientifically exact writing about chemistry of the underground and magnets was always interesting.

15.7.3 Idrija Pharmacist

Inzaghi's Idrija pharmacist Ernest Freyer (* 1729 Žatec (Saaz, Satz) near Ohr in the Sudetenland († 1795, Idrija No. 136) worked between 1754 and 1795. Johann Jacob Wecker and his namesake Johan Jakob Becher was among Freyer's most popular writers; Freyer got their semi-alchemical works like De Secretis alchemiae Briefe,[1825] Physica Subterranea Opus Sine Pari (Leipzig: Weidmann, 1738) and Chemische Schriften.[1826] E. Freyer manually copied the book (of Becher's Viennese colleague Wilhelm von Schröder (* 1640, Prešov in Slovakia; † 1688): Nothwendiger Unterricht vom Goldmachen, denken Buccinatoribus oder so sich selbst nennenden foederativ hermeticis auf drei Epistel zur freundlichen Nachricht. The book was published in 1684, and Freyer used a reprint from 1721 on public finances and alchemy titled: Wilhelm Freyh. von Schrödern Fürstliche Schatz- und Rent-Cammer: nebst seinem Tractat vom Goldmachen wie auch vom Ministrissimo or Ober-Staats-Bedienten (Leipzig: T. Fritsch). On 3 April 1661, 6 June 1661, and 9 June 1662, Schröder reported to Gaspar Schott from London on Boyle vacuum pumps and other devices. Schott[1827] as Kircher's pupil published the first printed description of the Guericke's Vacuum Pump. Freyer also transcribed Conspectvs Chemiae Theoretico-Practicae: Tomus ... In Forma Tabvlarvm Repraesentatvs, In Qvibvs Physica, Praesertim Svbterranea, Et Corporvm Natvralivm Principia, Habitvs Inter Se, Proprietates, Vires Et Vsvs, Itemqve Praecipva Chemiae Pharmaceuticals Et Mechanicae Fvndamenta E Dogmatibus Becheri Et Stahlii ... Explicantur ... (Halae Magdeburg: Orphanotropheum, 1730). The work was compiled

by Johann Juncker (* 1679, Londorf; † 1759, Halle) with the help of Juncker's predecessor at the Department of Medicine in Halle, George Ernst Stahl (* 1660, Jena; † 1734, Berlin) based on the reflections of the Viennese alchemist and businessman Johann Joachim Becher (* 1635 Speyer, † 1682 London).

Freyer drew many alchemical symbols to illustrate the joining of elements; he was obviously interested in the eighteen decades old Viennese mercantilists and cameralists Schröder and Becher, and even more so in the modern Scandinavian crystallography and the pharmaceutical botanic edited by the Jesuits in Graz. Freyer continued to cultivate the alchemical traditions there in Carniola and Bohemia a century and half after the alchemistic Rudolf’s court in Prague.

The association with Ljubljana's high society was necessary for 24-year-old E. Freyer to become the temporary leader of the pharmacy in Idrija following the order of Minister G. van Swieten, although on 20. 1. 1755 Janez Anton Scopoli (* 1723; † 1788) through the director Sartori asked the Viennese court to approve his preparation of medicines and the management of a pharmacy with an additional salary of 800 per year. On 20 September 1754, Sartori did not support Scopoli, as the doctors at that time were not supposed to supply their patients with medication because of the huge possible profits involved. C. Weinhardt offered Sartori the equipment and care of a pharmacy at a lower price of 400-500 per year. He also promised to provide an experienced person for the job of pharmacy manager. An unnamed specialist was, of course, Ernest Freyer, who allegedly joined the Carniolan experts of those days as a candidate for the apprenticeship (tironcinium) at Weinhardt’s class Scopoli was not lucky enough to obtain a pharmacy on Freyer's behalf, but they continued to cooperate well; Scopoli, of course, tried to enforce Freyer and Hacquet’s participation in some of Scopoli’s own work, but they tried to avoid that funny honour one after the other. Of course, there was a great social difference between Scopoli and Freyer, and even greater between Scopoli and Inzaghi; their social ranks are well-documented by the notes on godparents for children, since Freyer was not involved in the noble baptisms or weddings. On the other hand, in 1783, Inzaghi's relative Volta described the eudiometer for Scopoli’s extended translation of the Dictionary of Chemistry of Pierre Joseph Macquer, which was surely a great honour for young Volta at that time.

Gregor Schöttl took over the department of physics-chemistry in Ljubljana on 22 October 1768, simultaneous with the arrival of G. Gruber to the College. The following year, Schöttl became a professor of moral theology, a professor of philosophy and confessor. Upon his arrival in Ljubljana, G. Schöttl donated to Jesuit library his books, which included his undated bookplate “In Soc. Bibl. Phil. Coll. Lab. S. J. Dono P. Greg. Schöttl”. Among the donated works was a genealogical survey of the (princely) Counts of the Celje, connected with the examination theses, which were defended by the heritage-canon of Halberstadt and Hildesheim, baron Edmund Brabeck, a student of the second year of physics, mathematics and history under supervision of the professor of physics, numismatist Erasmus Frölich (Fröhlich) at Theresianum. Fröhlich was a member of the Societas incognitorum eruditorum and terris Austriacis, led by Joseph Leopold Baron Petrasch (Petráš, * 1714, Slavonski Brod; † 1772, Neuschloß in Moravia) in Olomouc from 1746 to 1751, together with Gerard van Swieten and professor of mathematics in Olomouc, Joseph Lewald.

In his special physics, Frölich described fire, phosphorescence, underground fire, thermometer, weight of the atmosphere, mercury vacuum barometer, similar siphon, hygroscopic, waterfalls, movement of the compass with reference to Bošković, steam, mist, rain, halo, rainbow, the electrical light and spreading of electricity.

He explained the causes of the heat of the sea and freezing, the types of earths or metals, the motion of a needle in a compass, and in this especially emphasized the opinion of then still young Bošković about magnets. This early mention of Bošković, as the only contemporary writer cited, ranks both Frölich and G. Schöttl among his early advocates. Frölich explained his electricity without any connections to magnetism. He described the attraction, reflection, light, and the spread of electricity.[1828]

[1828] E. Frölich, *Genealogia Sounekiorum comitum Celeiae, et comitum de Heunburg specimina duo conscripta ab Erasmo Froelich, p. J. Mariae Theresiae Augustae dicata: cum sub Augustis eiusdem auspiciis Edmundus Lib. Baro a Brabeck*

G. Schöttl was the advocate of Newtonian science in Bošković's form, which was common-among the Jesuits of his time. He dealt with vacuum and pores in the bodies.[1829] He asked his students whether all the bodies were porous and wished to judge the size and shape of the pores. It was necessary to know the Cartesian, Epicurus, Gassendi, Newton and Leibniz's opinions on pores.

15.7.4 Conclusions

In the territory of today's Slovenia the Idrija mine manager Inzaghi among the first promoted Volta's vacuum novelties as the close relative of Alessandro Volta. He voluntarily supported the prints about Voltaic discoveries promoted by the Jesuits of Ljubljana. In Inzaghi's time, the Jesuits of Ljubljana quickly acquired Voltaic inventions, especially Volta's pistol (eudiometer). Collaboration took place in both directions, especially after Volta's takeover of the chair in Pavia, where the former Idrija physician Scopoli also taught. To renew the lessons at the Volta's Pavia, supported by Emperor Joseph II and the main Lombardian businessman-statesman after 1765, the Koper native Count Gian Rinaldo Carli (* 1720; † 1795), they required a relatively large amount of well-purified Idrija mercury for Volta's thermometers and barometers. Inzaghi's pharmacist Ernest Freyer designed many improvements in the production of Idrija mercury.

15.8 Vacuum Gauges by Tobias Gruber

15.8.1 Introduction

Among many Idrija visitors and explorers of mining vacuum devices, Tobias Gruber was especially distinguished, which we described our other works . Therefore, we prefer to focus on the inventions of T. Gruber's portable vacuum gauges; with them he became very famous, so they were still used on the scientific journeys for a good decade after his death. He could inventively adapt his inventions to the somewhat uncomfortable conditions challenging early explorers of the mountains.

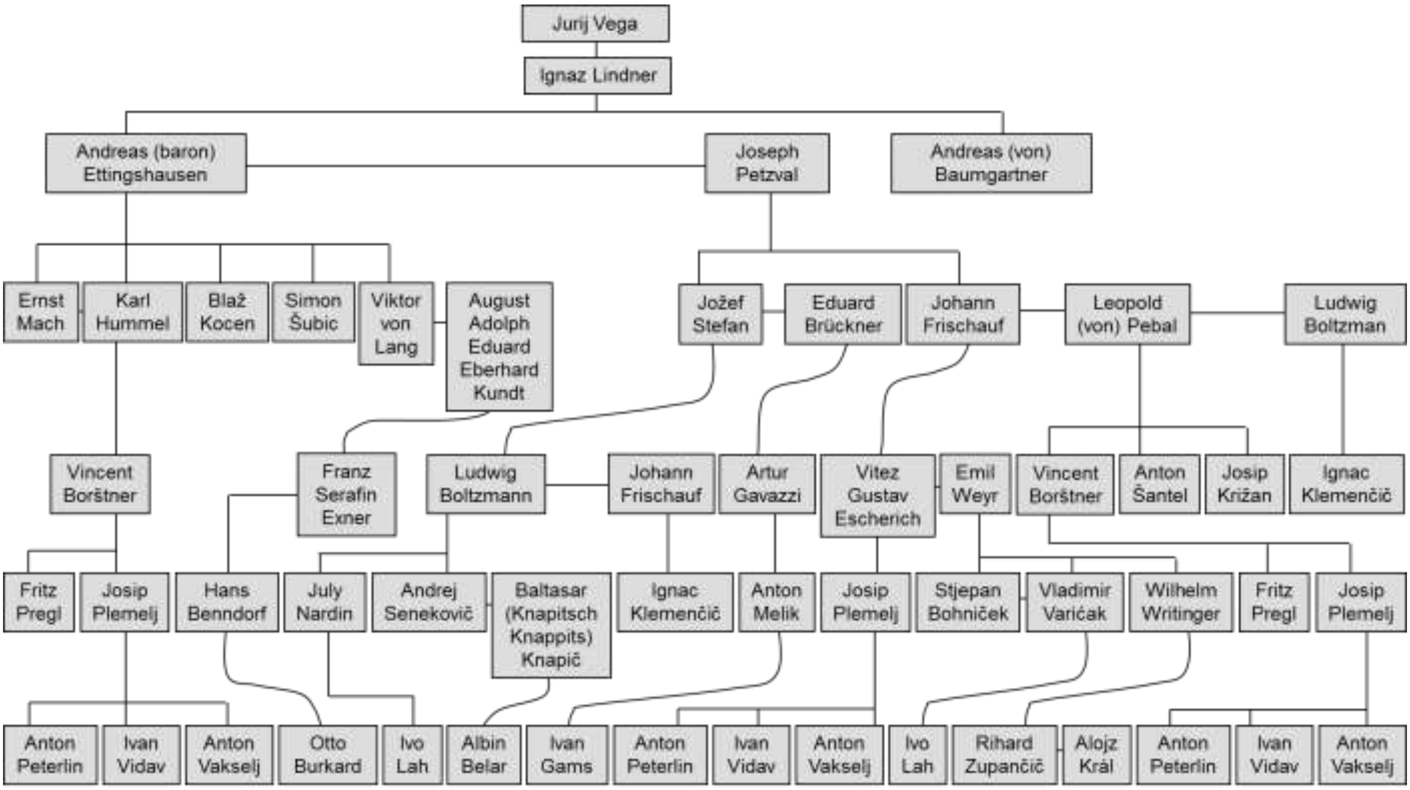

Figure 15-48: Academic ancestors of Vega and other Slovenian users of vacuum techniques through the centuries

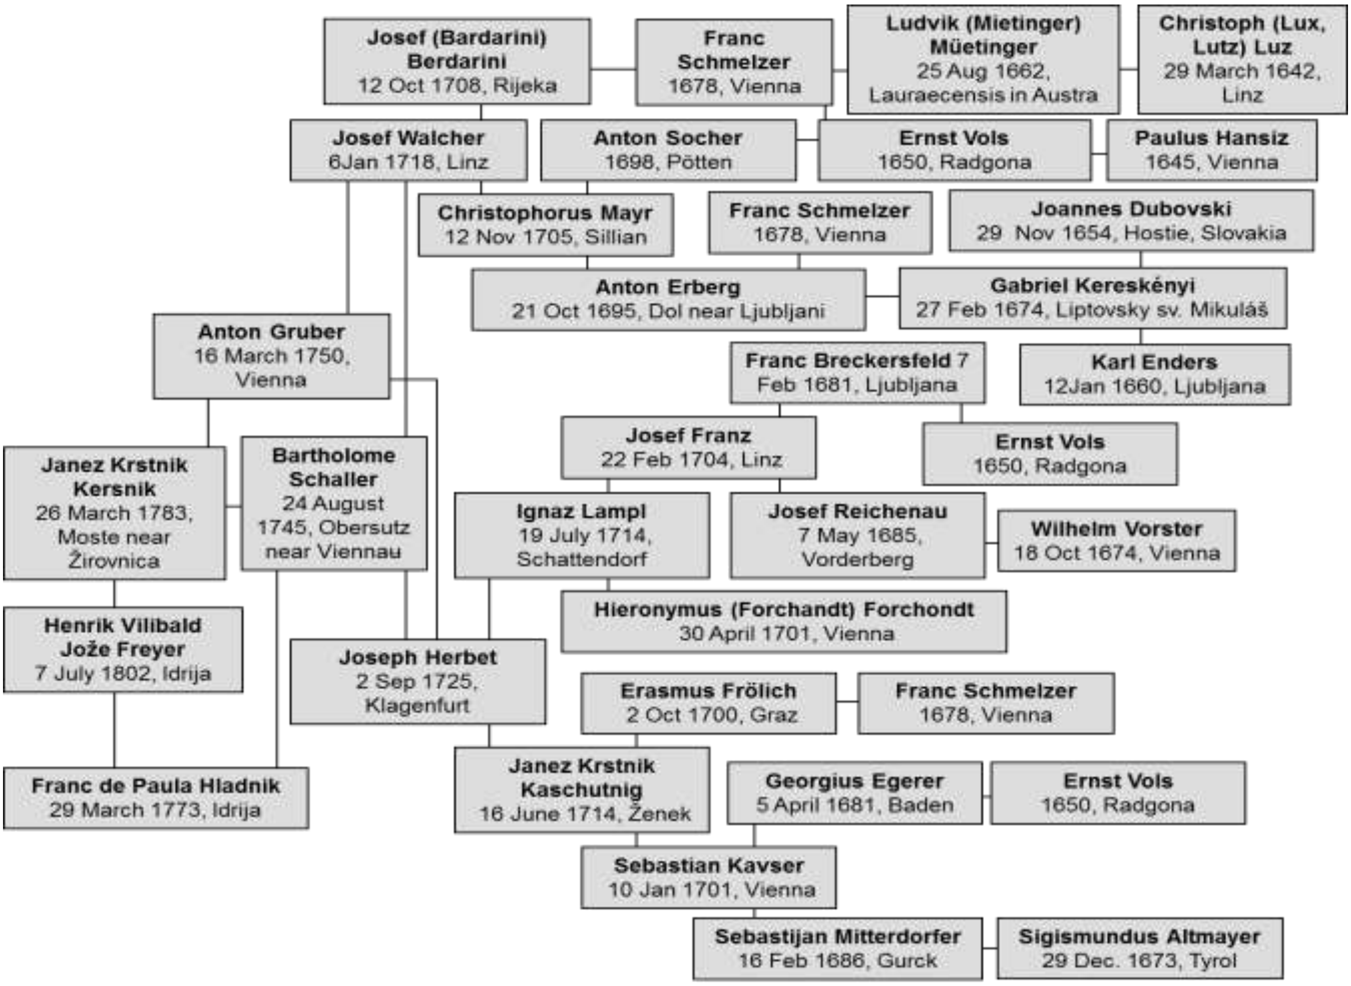

Figure 15-49: Academic ancestors of the professor Henrik Freyer.

The Viennese Jesuits of Gruber family were brothers and not just half-brothers; the facts became evident from the Viennese baptismal and funeral records. The influence of Gruber's brothers on Carniolan everyday life was such that the last third of the 18th century could be called the time of Gruber. Their importance soon spread beyond the Carniolan and even outside the Habsburgian borders. They have decisively contributed to the restoration of the Society of Jesus throughout the world, which, to a certain extent, has always been the main goal of their actions and negations. In that context we could interpret Tobias' autobiography, dated October 1804.

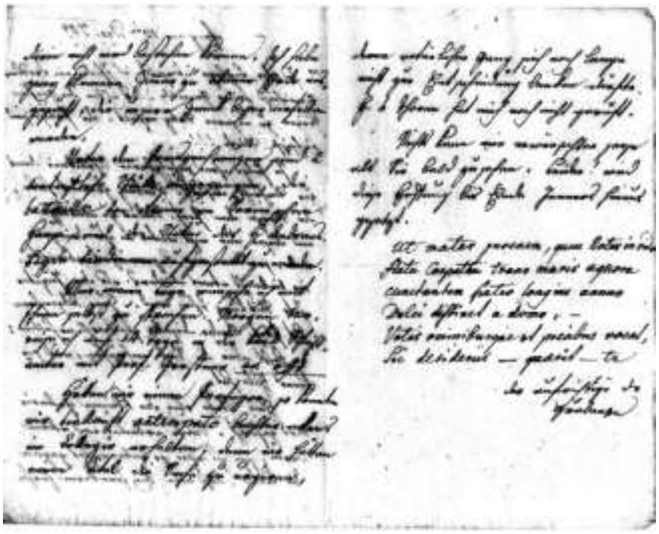

Figure 15-50: Tobias Gruber reports to F. Sternberg about his friend, Professor Gerstner, on the left side of the letter, which on 13 December 1797 concluded with a long Latin poem about exploring of the Carpathians using vacuum portable gauges of Tobias Gruber's own production (Archiv Národního Muzea, Praha, Šternberk-Manderscheid Fund (ŠM) k64).

15.8.2 Evaporation in Vacuum in 1788

In 1788 at his beginning of the paper on the evaporation of water in an empty space, T. Gruber quoted two years earlier research of the barometric tubes of his friend Gerstner. Franz Joseph knight Gerstner (* 1756; † 1832) found that drops of water in the empty space of the barometer flew away and their modifications can be observed under different circumstances. The phenomenon in two successive winters enabled his series of experiments, whose extracts and results were described by T. Gruber in detail in his discussion. He used straight (linear) glass tubes 45-50 inches long with diameters of 3-4 Viennese lines; today obsolete unit of measure "line" then measured about 2.2 mm. The tubes were almost horizontally sealed at the ends and filled with purified mercury; Gruber bought it in Idrija and boiled it for so long as possible. Cooking and the evaporating of purified mercury vapors at +356.73 ° C is a very dangerous process from the modern point of view, but, despite Hacquet's research, T. Gruber did not know much about these dangers as brothers Gruber used to quarrel with Hacquet.

T. Gruber then used an open tube full of mercury; when it twisted it by half of a full angle, therefore for 180°, the mercury was placed in an equilibrium position balanced with an empty space, at least 30 inches long. So, he got a barometer in Torricellian century old way. To introduce water into the barometer, he used a calibrated glass syringe, whose conical curved end flowed into an opening narrow as hair with a diameter of 1 7/12 lines. During the shaking of the measuring device, the experimenter T. Gruber noticed a compressed mass of water, which climbed by 6 2/5 cubic lines. When the water rose to the surface of mercury, it was squeezed out and created an air balloon, the size of which was very close to the size of the tube's diameter. The mercury level dropped 9 lines right after the splashed squeezing. The collected water can take up more than 3.5 cubic meters of volume while raised to a height of 28 inches and 7.25 lines at 14.9 degrees Réaumur in the area between mercury and balloon of air.[1830]

The weight of 9 lines high mercury above the water mixed with air pressed together with the weight of the water mass. When the tube was lowered, the balloon rose by 1.5 lines, which gave a drop of 3 lines and a further ¾ of a line in the entire barometric vacuum.[1831] The evaporation was much slower than in the open air. In the ensuing experiments, T. Gruber endeavored to prove with certainty the conditions in the absence of air or in an empty space; the phenomenon was described like that in water, where the air was also removed. At the first major warming of the empty space with the flame of the spark-burner, only a change in the mercury tube appeared. It received from 0.5 to 5/6 cubic lines of water, enclosed in an empty space,

[1830] The Réaumur scale, without serious use in modern science, endorsed the slightly greater degrees than today's predominant Celsius' scale (in a relationship 1°R = 1.25 °C.
[1831] Gruber, 1788, 141.

which enabled Gruber to experiment with the water's dependence of the glass walls. By extending the area of water to the surface of mercury, the last trail of air disappeared. The mercury rose 9 lines at a temperature of 15 degrees of Réaumur. The water formed a ring in the middle of mercury with a taut mercury surface formed as a tense membrane. The mercury in the capillary, unlike the water, does not wet the wall. With the heat of his hands, T. Gruber heated the surface of the mercury in the tube; the water completely evaporated within a few minutes, and in the upper part of the tube made visible droplets. If we take the upper part with the hand, the water will collect under mercury. The empty space was more or maybe less heated.[1832] Thus, with a little heat, water mists and ever-increasing droplets, which are finally placed on the glass, can be quickly obtained. In the middle of the mercury's surface, isolated drops are formed in the form of spherical segments. Gruber experimented at different temperatures of empty space, and mercury had to have a different temperature level compared to the empty space. He looked for the cause in an (averaged) lower triple point of mercury, in a greater attraction with which the increased hemispheres are polling the center, or in both. Even at different temperatures, for example, at -14 degrees of Réaumur, Gruber noticed similar isolated drops. If the temperature is reduced to -17 degrees across the entire device, the drop of the mist will increase, so that mercury is placed only 5/6 lines lower in the barometer. More heating causes large evaporation of mist. With a spark flame that increases the free space temperature by 50 degrees, in the pipe of 4-line diameter mercury will fall by 7 inches 2 1/3 lines below the normal level; in a room with a volume of 2 4/9 cubic inches with a 11/20 cubic line of water, the mist will be invisible.

At a temperature of +80 degrees,[1833] mercury will be at the level 12 inches and 1 line and the mass of the water of the 2/3 cubic line will be invisible in a larger 2 2/3 cubic inch space. The evaporation of the water at -14 degrees of Réaumur is very small; up to a boiling point at + 80 degrees Réaumur, when the 2/3 cubic inch of water is invisible, the difference is 94 degrees, and the contribution of the empty space to the amount of evaporation is 97: 56.

For T. Gruber, as for many modern scholars, a vacuum was nothing in the first place, but it has properties that greatly influence evaporation and related phenomena. In his laboratory Gruber again successfully illustrated events in nature, and his ideas resembled a lot a subsequent cloud chamber (foggy cell) "invented" a century and a half late.

The temperature of the boiling water in the empty space was reached by T. Gruber with a (bleached) iron wire. Gruber attached it to the measuring device as deeply as it was possible in an empty space. T. Gruber warmed the wire to hot melt at 356.73 ° C in a glass tube of a tempered mercury thermometer. The thermometer was so warmed in a certain position that the volume of mercury increased by 1/4 cubic lines in 1/6912 part of the entire space. In the raised tubes, the water reached the surface of the mercury column and squirted a 10 inches high column of water that surrounded the entire thermometer. At +26 ^{o}R (30.5 ° C), as brought by the warmth of T. Gruber's palm, he observed a bubble of vapor as big as an approximate diameter of the tube. At +34 ^{o}R, as measured at his a warm suit, the boiling of the mist by the ground was already so severe that the water covered the entire empty space without any resistance up to the end of the tube. The measurement level in the thermometer has risen by 1.5 lines. The mean value of several observations was +30 ^{o}R according to T. Gruber's calculus. At a temperature of -15 ^{o}R, 8.25 inches long closed-water column appeared in an empty space, which increased by a 1/18 of its length by a convex surface.

A closed thermometer received a lot of ice so that the elliptic layers formed on the surface; crystallization on the edge of the glass was generated even at 0 ^{o}R, as well as at -15 ^{o}R.

The change in the mass of the air for a half-cubic line of water occurred at different degrees of heat. With the known difference between the specific mass of water and air, the dry air in the middle of the splashing was compressed in the same way as under the pressure of the half of a cubic line of water. When Gruber warmed the entire airspace with a sparkling burner, mercury was boiling; the mercury column has risen only 1 inch and 6 lines from the initial value. At ice temperature, the increased distance was only 9 lines.[1834] For pure

[1832] Gruber, 1788, 142.
[1833] Gruber, 1788, 143.
[1834] Gruber, 1788, 144–145.

water, the level was only 4 1/3 of the line above the original state. From these experiments, T. Gruber derived the following conclusions:

the heat in mercury that brings water to boiling temperature is also transferred to the air by heating, so that the mercury column must decrease.

Similarly, air becomes visible in boiling water in an empty space;

the air is, as a matter of fact, a ponderable fluid substance, is extracted just a little bit at the cooking temperature (of water).

The atmospheric air does not appear during evaporation, since it is enclosed in water, where it is further expanded.[1835] When the water is rapidly cooked, the air is placed at different altitudes in its interior, which results in maximum water extraction.

T. Gruber believed in the materiality of heat and fire; in German language it was called Feuerstoff, while for the Slavic people or Frenchmen it was caloric. Such a substance is evaporating in an empty space. More or even less water is eliminated; such fog results only from collisions between substances. At high heat rates the vapour diminishes and hangs on the walls, while the caloric is only transmitted. T. Gruber's caloric resembled the ordinary fluid substances, but much lighter which might have been in accordance with Lavoisier's original ideas announced in those times.

In the same heat rates, T. Gruber allowed only a certain amount of heat lost into space, while mercury remained at the same level and could extract more or maybe less water. For the evaporation in the open air without steam, he also considered humidity in addition to the degree of heat.

The laws of static were not enough for Gruber's explanations of the movement and circulation of the fog (mist) in an empty space,[1836] followed by heavier or lighter particles. Apart from the heat and other intermediaries that go through the glass, there is nothing else. Apparently, the extraction and evaporation of the water affects the mass of water; so, the steam effected heat or caloric. Similarly happens with other substances penetrating the glass. While the vapor itself forms an intermediate medium where each particle has a certain distance from the other, only the fire in the coming or exiting of the company with other liquids causes refraction between the vapor particles. Gruber did not support the assumption that all water vapor is produced only as bubbles because the vapor is swirling according to the laws of statics.

In these circumstances, the part of swirls go through the hollow body of the vapor as hollow spheres, whose specific weight alone remains the same; on the one hand, the vapor joins with pieces of fire. In the atmosphere, the excessively heated volume of air in addition to its vapors is difficult to describe with static derivatives because of reflections on small parts of the air.[1837]

The heat and caloric are compatible with other liquids that pass freely through the glass. Apparently even in an empty space heat and caloric form an intermediate medium; so, much vapor is excreted as the amounts of intermediate particles allow in the ratio of steady amount of steam. This dependence is a consequence of the affinity of steam on fire.

At -13 ^{o}R, mercury under the vapor space is lifted by an additional 1.5 lines and at -17 ^{o}R for the additional 5/6 lines, like that in the barometer; so, it is understandable that the excretion and liquefaction of the vapor can occur only at higher temperatures under the influence of heat and caloric power.

Five years before the writing of T. Gruber, Lavoisier in his Réflexions sur le phlogistique (1783) proved that phlogiston opposed the experimental results; so, he replaced it with caloric. As it is always happening, the caloric has cleared up some of the problems, but soon he has come up with whole great ranges of new ones.

In 1798 Count Rumford published An Experimental Inquiry about the Source of the Heat, which is excited by Friction. He reported about his observations of drilling new cannon tubes. He proved that caloric is not maintained; T. Gruber accepted Lavoisier's position, but he did not think in Rumford's way yet. Rumford succeeded

[1835] Gruber, 1788, 146.
[1836] Gruber, 1788, 147.
[1837] Gruber, 1788, 148.

Lavoisier in several ways. Among other things, Rumford inherited Lavoisier's widow, which he regretted bitterly. Unfortunately, repentance did not save him from the flying pots of his carelessly chosen Parisian bride, who had all too quickly turned into a dragon. The Gruber brothers as monks mostly avoided such problems.

T. Gruber changed the steam or fog in an empty space with slower or faster evaporation. In the air, under normal conditions, such a rapid and vigorous evaporation does not work. The steam was supposedly connected to the caloric. The dense caloric content more or maybe less retained the steam, which is, therefore, condensed somewhat slower. In this respect, fire seems to be the same as its media: its unified with the vapor and covers the to allow only the motions in the intermediate space.

The fine thin atmospheric air is diluted with heat or by lowering the pressure. More vapor is obtained from denser substances. When passing[1838] through the denser to the thinner air, cloud areas and then precipitation are created. Then the fire again forms a liquefied vapor. It was the same idea of circularity which Tobias' brother Gabriel used to explain the flooding Mountain Field (Planinsko Polje) connected with Ljubljana marshes and Ljubljanica river.

Regardless of the temperature, the pressure rarefies air while the steam is left behind; so, the air is dependent on fire. This can be a good basis for the interpretation of contributions to other phenomena, Gruber added. Among other things, he had in mind a lot of moisture even in the case of reduced heat, humidity in the upper unbalanced areas of the atmosphere or moisture in the form of precipitation.

With the same degree of heat, humidity (vapour) will be less dense than the ordinary air when the humidity and air are equal in their masses. When it's cold, we get even more moisture or fog. At the same heat level, when both (humidity and air) have equal volume but unequal masses, the entire room of moisture-fog at lower temperatures is smaller than the ordinary air space.

From this it follows that fire with high elasticity of vapor-moisture produced by air increases in proportion to the amounts of spaced spheres (of its molecules). Consequently, humidity in variable intermediate media makes a major change with the increase and diminish of its mass; like the colder air. Gruber tried to prove by his experiments that the elasticity of one and the same volume of air increases with the removal of moisture which would probably challenge the later Dalton's law. The air does not affect the crystallization and expansion of ice.[1839]

The crystallization takes place in water with a certain removing of the flames, which adds liquids by secreting its own elements; they make regular crystalline forms according to the laws of attaction. On the other hand, the distances are greater in intermediate space in the liquid (due to water anomalies) compared to the (same) volume of ice, even when it is completely free of air.

Part of the air is transferred to ordinary water; when it rests, an even greater part of the air in other bubbles appears in ice. Gruber explained the anomaly of water with the unmovable hard ice; therefore, it has for 1/1015 smaller volume compared to the volume of boiled water, where it has only 1/1212 of volume of the free air. In a cooked medium, which is removed from the empty space, it retains only 1/18 of the mass of liquid.

There T. Gruber inserted a distinctive remark about different experiments with the translation of substances through an empty space of the barometer. He pointed out only one example: when we cook mercury for the second time, we do not change anything with strong heating of the vacuum; it remains void or has already been emptied.[1840] In this way, we can determine the specific weights of different gases and quantities of the fixed air evacuated from the liquid. The latter was the term of the Scotsman Joseph Black (* 1728; † 1799), coined after 1753 for gas, now called CO_2.

Similarly, we define condensation or liquefaction, mixing and synthesis of the substances without considering the air; we can find many other phenomena. This increases the scope of physics with attention focused on the (constituent) particles needed to continue and complement experiments

[1838] Gruber, 1788, 149.

[1839] Gruber, 1788, 150.

[1840] Gruber, 1788, 151.

or to continue the experimentation under different circumstances.

Following his research of the barometer in 1788, in 1790/91 T. Gruber published a paper on the particles of the atmosphere, in which deeply he engaged in the atomism of particles of air associated with fire or caloric. He first stated his own finding in 1788: in a vacuum the evaporation of the water is improperly faster than in an air-filled space; in void the water boils at 30 ^{o}R (37.5 ^{o}C). He imagined fire as fluid inelastic substance; it does not have a reflecting zone associated with the intermediate particles but forms at least a temporary reflecting zone which further prevents the once interconnected substance from reassembling particles of fog into their renewed mutuality in their interim space.

Thus, the fire itself and its repulsive force cause the substance to rise without additives even if its heavier than air. Fire is lighter and less elastic than air; therefore, it tends to rise and distribute throughout the space. Caloric establishes a balance with its expansion into areas with less caloric to achieve a balance in foggy vapour.

Fog with its vapor became denser or diluted due to temperature differences between its warmer and more cold parts, thereby triggering its own circulation.[1841] The heat influences the mist by wrapping it with warmth, thus allowing the round shape of ordinary drops of mist or fog. More space in the intermediate air means more space for foreign particles. The air, expanded by heat, can also accommodate more foreign particles compared to denser air that has less heat.[1842] The higher level of impregnation of free air (with vapours) might make it a subject to the laws of hydrostatics. Weight or mass of the body is always a product of its volume and density. Some traces of rain from clouds never reach Earth's surface.[1843] The areas of clouds have coagulated voluminous vapors. In the lower regions formed along the Earth's surface, the solar rays are highly influential, which T. Gruber proved with a quote from his discussion on fata Morgana measured above the lake Cerknica.[1844] At some heights, the balls of vapor are spherical.[1845] The equally shaped steam spheres are much more condensing. The process can be so fast that the steam solidifies (after sublimation). Among all the polyhedron that emerge on the vapor balls, Gruber emphasized icosahedra with twelve identical vertices. Twelve spheres of steam form them by actions of caloric, which also affects the transparency of the vapors;[1846] of course, it's just about an approximate description. In the correct form of icosahedron smaller bubbles merge and form larger ones. Some of them can become so large that they look like fog or cloud.[1847] The steam is formed according to the surface, especially in high mountains. If we measure the vapor density along the whole atmosphere, we get a curved line for the ordinate. It is affected by sun rays, as are heat or cold. Clouds in the atmosphere that alter the mentioned curvature are also adapted to the shape of the Earth's surface; after the split the steam gets a minimal spherical shape, and the amount of caloric in the air decreases to zero at higher elevations.[1848] The electric fluid is, of course, part of the atmosphere; its exceptional fluidity and elasticity allow high speed of electricity. Positive and negative electricity is a modification of the same substance or two different; Gruber wrongly considered that the second assumption had good support in experiments, but this or that theory did not affect his model. Positive and negative (electricity)[1849] are more suitable for point-contact bodies, where they can form a smooth surface like atmosphere that moves due to air’s reflection, as well as because of modifications of steam in balloons; therefore, it affects the recharge of clouds.

The reflecting pairs of balloons of vapours, reinforced with electricity, flow easier, allowing clouds to move in higher areas of the atmosphere. In the footnote, T. Gruber emphasized A. Volta's view that electricity influences the formation of steam; that was Saussure's assumption demonstrated during the numerous experiments described in the third part of his travelogue *Reise durch die Alpen* recently published in Leipzig in 1781-1788. With its high density at the surface of the earth, the bound electrics rise, and with it the

sublimated particles of the earth. Mountains within the clouds act as conductors. Thus, electricity (in the atmosphere) is a kind of boundary between air and earth. Positive and negative (electricity) modify the steam, that can affect the atmospheric pressure and the steam curves, all which result in uneven density. The magnetic substance is widespread throughout the atmosphere and its parts and is not separated in its modifications. The magnetic substance can be transformed into electricity to a degree that is defined by the circumstances; this idea of T. Gruber was undoubtedly modern in the frames of then popular romanticism and *Naturphilosophie*, as Oersted proved it only in 1819, and later Faraday adjusted it to electrical engineering.

Indeed, Benjamin Franklin was thinking about the effects of lightning on a magnet earlier, as did Tobias' brother Gabriel Gruber in the then Russian town of Polock in the present-day Belarus.

T. Gruber did not just stop by the caloric, electricity and magnet, but also reflected on the last remaining fluid that was imagined then, without any weight: the light. Light should also occur very often during the spread of caloric in the atmosphere. It spreads on straight lines and is very different from caloric, as it can be seen. Light can affect heat and cold without changing atmospheric pressure. Then T. Gruber went even further with the assumptions about many other fine substances, which science was never able to define. T. Gruber considered that his research enabled him to look at them, although they cannot be easily traced in nature. In further exploration of the atmosphere with various useful types of gases, T. Gruber assumed many not yet discovered substances. The movement of comets looked like balls of steam, assuming that then modern exploration of cold areas by the Earth's poles would bring many new discoveries. When comets from large distances and frosts approach the warmer atmosphere of the Sun, their warmer core emits fluid; this very fine substance makes them visible beyond the Sun. T. Gruber has rhetorically asked: "Is not the stock of fluid substance in the poles (where warmer zones are replaced by colder ones) with the Aurora Borealis the same as comet's material?" Perhaps he had in mind the presumptions of his friend, the Jesuit Maximilian Hell. According to Gruber, we are dealing there with remote modification of the atmosphere,[1850] which at least for the comet is completely nonsense from today's point of view. The fire, light, electricity, magnetic material and many other less-known fluids cannot have the same weight as other substances, but their weight can be indeed demonstrated in the atmosphere; this weight is usually so small as to be detected only by the other (more precise) meters. T. Gruber expressed his different opinion about the parts of the atmosphere and its substance, which is to a certain extent fluid. He thought that these were oils derived from the modifications of balls of steam. He even encountered a semi-fluid substance in the form of refined dust particles raised from the fluids that differed from the atmospheric space because of its (greater) specific gravity. The second component of the atmosphere is reflected in changing of weather, decomposition and rotting of minerals, plants and animals. In solid substances, we have traces of salt. Gruber regretted that it precisely that part of all od them needs the most complicated explanations, although it appears on the surface of the Earth and does not work very far from us.

The reason for the poor knowledge of these phenomena is seen in their movement, which is different from that of fire or heat. We feel the warmth of the Sun[1851] as halfway through a steam that lies on a heated surface; therefore, the cooling of the Earth causes (dew, frost) to fall during winter nights.

The same ingredients also cause changes in the density of the atmosphere, as well as numerous features. Its a special gift to measure the density and perform the necessary calculations, since measurements can only be carried out in nature. Gruber certainly loved to do that himself with his ppwn designed portable tools. The reduced mass and the volume of a special ponderable substance itself causes a difference in the weight of the atmosphere.

The motion is not merely opposition to pressure; movement of the air particles in the direction of its weight also occurs. All phenomena of gravity are reflected as the consequence of a decrease in force, which in turn opposes the movement. The last result of all these surveys shows the geometric dependence of the density of air on the

[1850] Gruber, 1791, 205–206.
[1851] Gruber, 1791, 205–206.

atmospheric pressure. Thus, by measuring the density and weight of the air, we can obtain the same scale that Professor Gerstner described in his discussion. Gruber's geometric (exponential) dependence was certainly Laplace's barometric equation published only few years later in 1796.

The fire has particles that are not elastic because they do not have the appropriate repulsions between their intermediate particles; in at least one aspect, they have an impact power that lasts for so long as they can efficiently prevent the reunion of the particles. When the flame produces enough particles during the evaporation in the air,[1852] then their quantity remains the same to maintain the distance between the separate substances. If there are no other needs, the separated vapor particles will be kept scattered in the space.

The upgraded substance, heavier than air, will only be maintained at distances without any contact due to problems caused by fire and reflection.

The liquid substance is specifically lighter, even if it is more elastic than air; it therefore strives to rise and separates according to the laws that apply at such altitudes. Mutually balancing the substance of a fire to prevent its spread requires a balance between the steam produced, even if it is elevating. The movement of steam depends on the density and the temperature differences.

15.8.3 The Expansion of Gases in a Vacuum

As a physicist, Tobias Gruber loved the problem of formation of ice at the mine pump at Schemnitz (Banská Štiavnica), which was described by Tobias' teachers Scherffer and Poda,[1853] both advocates of Bošković's sciences. The pump was compiled by an elder brother of the leading Jesuit astronomer Maximilian Hell, who rejointed their restored Jesuits' society of Gabriel Gruber like Tobias did. Tobias began publishing his diluted gas exploration in 1788 when he moved from Prague to a long-term works at spa in Franzensbad (Františkovy Lázně). There he investigated the content of gases in mineral water and compared it with the measurements of Tobias' friend the count Franz Hartig (* 1758, Prague; † 1797, Dresden) at the Pyremont Spa in Upper Saxony, southwest of Hannover.

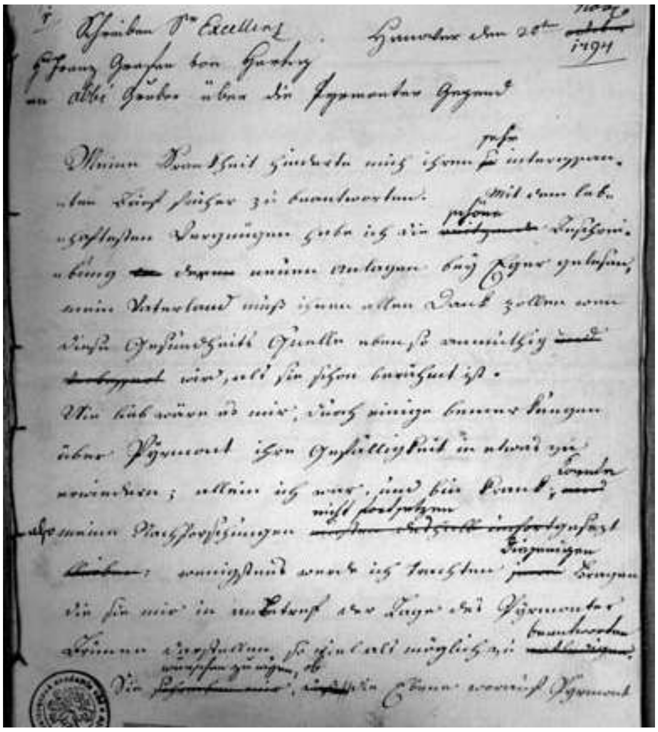

Figure 15-51: The beginning of the letter of the President of the Bohemian Scientific Society Franz count Hartig, sent from Hannover to T. Gruber's Bohemian Lands on 20 November 1794 (Archiv Akademie věd České republiky (Praha) / A. Fondy Instití / Fondy starších vědeckých společností, ústavů a spolků / Královská česká společnost nauk (KČSN) 1766-1953, 75, inventory number 508).

Tobias Gruber opposed Erasmus Darwin's explanations of the spreading of gas, which should always collect heat from the surrounding area. Namely, Gruber was more cautious than Darwin's new theory of caloric, and he thought that the flow of caloric affects the surroundings.[1854] Then-current Swiss-German interpretation of adiabatic phenomena has often been opposite to the British opinions, as it also used to be in later centuries. The Brits mainly discussed their puzzles on the meetings of the Lunar Society in Birmingham, of which Darwin, James Watt and Joseph Priestley were prominent members. Many members of the Lunar Society were not only supporters of the American Revolution, but they also loved the French revolution, which the Jesuit Tobias Gruber disliked; as always, the scientific beliefs have intertwined with the political stances. Darwin and

[1852] Gruber, 1794, 193.

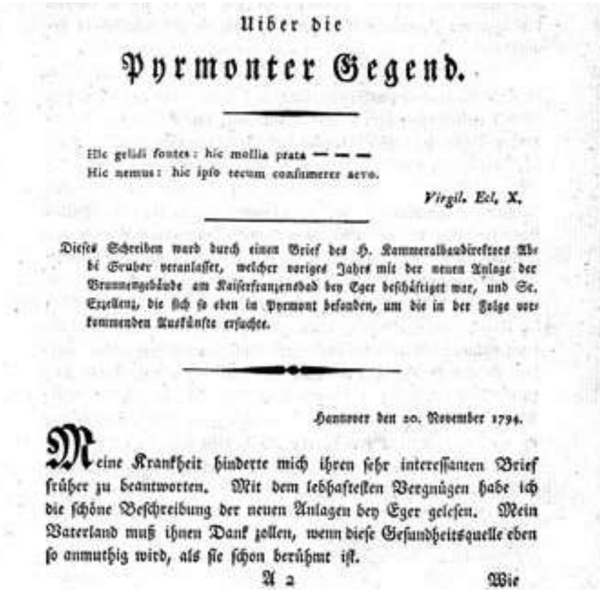
[1854] Gruber, 1791; Darwin, 1791.

Jean-André De Luc amongst the first realized that adiabatic phenomena cause compression of the air rather than filling the vacuum; that cognition was like the centuries-old reversal of Galileo or Blaise Pascal, who discovered that nature is not afraid of the vacuum, but the vacuum prevents gigantic pressure from the column of the atmosphere. Darwin and De Luc, therefore, did not favor the vacuum experiments, but Gruber, on the other hand, praised Darwin's wit and often quoted De Luc's achievements even in contrast to Lambert's measurements of the expansion of the air.



Uiber die

Pyrmonter Gegend.

Hic gelidi fontes: hic mollia prata — — —

Virgil. Ecl. X.

Dieses Schreiben ward durch einen Brief des H. Kammeralbaudirektors Abbé Gruber veranlasset, welcher voriges Jahrs mit der neuen Anlage der Brunnengebäude am Kaiserfranzensbad bey Eger beschäftiget war, und Se. Exzellenz, die sich so eben in Pyrmont befanden, um die in der Folge vorkommenden Auskünfte ersuchte.

Hannover den 20. November 1794.

Meine Krankheit hinderte mich ihren sehr interessanten Brief früher zu beantworten. Mit dem lebhaftesten Vergnügen habe ich die schöne Beschreibung der neuen Anlagen bey Eger gelesen. Mein Vaterland muß ihnen Dank zollen, wenn diese Gesundheitsquelle eben so anmuthig wird, als sie schon berühmt ist.

A 2 Wie

Figure 15-52: That same Hartig's letter was published in the Bulletin of the Bohemian Scientific Society with the added tables of measurements, and in 1795 it appeared as a separate book.

The researchers needed adiabatic phenomena primarily for the explanation of weather changes. Among Gruber's main sources, the measurements were made by his professor Carinthia native guy Josef Edler Herbert (* 1725; † 1794). T. Gruber extended his study of gases and their specific heat by several years of research with experiments in a vacuum, and he was especially impressed by the compilation of extremely precise portable devices for measuring the pressure, temperature, humidity, angles and boiling point of water. He has climbed up many important peaks of the Sudeten and other hills himself during his scientific journeys with colleagues, and his devices were used for a decade after his death. Gruber's portable vacuum gauges have become so popular that they have been called to evaluate similar devices manufactured by others. Among his assessments was the design of Viennese teacher Anton Felkel (* 1740; † after 1798) in 1794. Shortly after Tobias' relocation to the Bohemian lands, Felkel began to compile mathematical tables in collaboration with Lambert, though not exactly with great profits.[1855] T. Gruber advised Felkel to produce his small model, an extremely powerful and resistant tripod and a sketch on paper. The measuring device should be simplified to greater degree of accuracy, like that of a microscopic micrometer with a quadrant. With its 8 cm radius it was as reliable as a three-times greater radius. By the way, T. Gruber insisted that Felkel's device be properly handled to ensure effective use. In Prague, Tobias Gruber soon became a leading scholar and art expert, so he was entrusted with the leadership of the Czech Scientific Society (Česká Společnost Nauk), as soon as it gained the imperial patronage. Gruber was elected twice more as the leader, and at the same time he headed the secretariat of the mathematical-science class of society; in the old years he became the secretary of the entire society, the forefather of today's Czech Academy of Sciences.

15.8.4 Vacuum Measuring Instruments

Tobias Gruber proved to be a true artist in the production of vacuum scientific measuring devices. On October 31, 1790, the cousin of F. Sternberg, Joachim~~,~~ Count Sternberg (* 1754/5, Prague; † 1808), joined the Frenchman Jean Pierre Blanchard when he flew with a warmed air balloon near Prague. The severe storm was the beginning of the ruin of J. Sternberg's most carefully collected measuring devices; followed by a compulsory landing that caused Sternberg to bleed blood. He decided to engage in scientific activities on earth in the future, but not in the air anymore. He was a member of the Česká Společnost Nauk and of the Regensburgische Botanische Gesellschaft, founded on 14 May 1790. On 26 March 1793, Joachim Sternberg described his Petersburg meeting with the Ambassador the Carniolan Ludvik Kobencl (Johann, * 1753, Brussels; † 1809) and Lord James Macartney who traveled to negotiate with the Chinese Emperor. Joachim discussed with mathematicians Euler and

[1855] Archive of Czech academy of sciences KČSN box 79, inv. no. 374; box 85, inv. no. 504; http://www.scs.illinois.edu/~mainzv/exhibitmath/exhibit/felkel.htm

Shubert[1856] about the use of Tobias Gruber's devices for meteorological measurements in Norway and Sweden; Johan Albrecht Euler (* 1734; † 1800) was a member of the Academy since 1766, the conference secretary since 1769 and Leonhard's son. With T. Gruber cooker, Joachim determined the boiling point of water north of Hamburg; he quoted the records from Tobias's travelogue,[1857] and personally collaborated with T. Gruber for glassworks.[1858] Joachim's brother Caspar Maria Sternberg (* 1761; † 1838) together with Tobias friend Franz Sternberg-Manderscheid co-founded the Vaterländischen Museum in Prague in 1821, and he corresponded with Goethe after 1820.

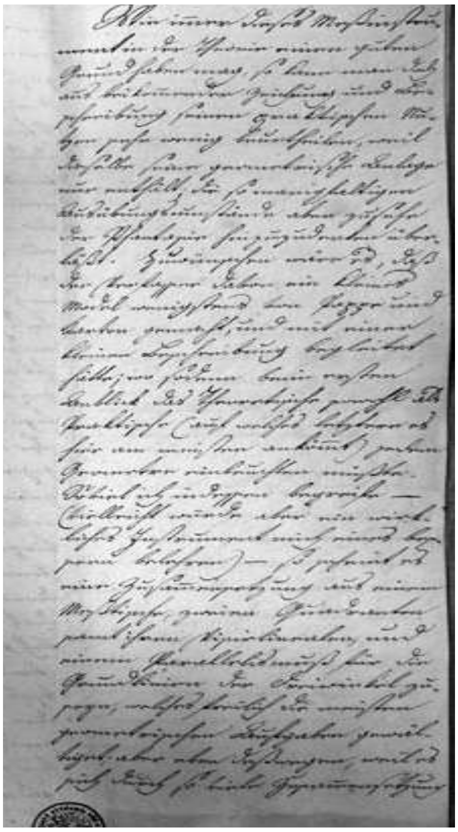

Figure 15-53: The first page of T. Gruber's Book Review of Anton Felkel's vacuum measuring device (Archiv Akademie věd České republiky (Praha) / A. Fondy Instití / Fondy starších vědeckých společností, ústavů a spolků / Královská česká společnost nauk (KČSN) 1766-1953, 75, inventory number 504)

Euler's and Shubert's examination of Tobias' measuring devices has smoothened the way for similar inventions designed by Tobias' brother Gabriel at the Petersburg Academy. The assistant to G. Gruber in Polock, the Bavarian mechanic, blacksmith and watchmaker Franciszek Ksaver Shopfer (Schoepfer, * 1761; † 1808) composed mechanical mills and a cloth cutting device. The invention was first used successfully in the Jesuit factory in Polock; then it was shown in St. Petersburg and Moscow. Peter Aleksevich von der Palen (Pahlen, * 1745; † 1826), the military captain of the capital and the Major Chancellor of the Maltese Order, reported on the new device to the Tsar[1859] whom he later helped to kill. In June 1799, when visiting St. Petersburg, Gruber presented some of his inventions in the Academy's premises,[1860] among them again scissors for cutting a thin cloth, various pumps and sculptures; he made a great impression and he himself aroused everybody's attention. On this occasion, he met again the Tsar after the Tsar invited him to the Winter Palace in 1789 and after the calligraphic description of the proposal by Franciscus Xaverius Kareau (Karü, * 1731; † 1802) for the presentation of the Jesuit mechanics to the Petersburg Academy. In the Winter Palace G. Gruber enjoyed the company of J. Benislavsky, who became the Russian Catholic metropolitan in 1800.[1861] The academicians, professors of mathematics Semen Emelyanovich Gurev and Semen Kirilovich Kotelnikov were interested in G. Gruber's works in the hydrodynamics. Gurev studied hydraulics in England in 1792, and Kotelnikov studied under supervision of the professor Abraham Gotthelf Kästner in Leipzig between 1751 and 1752 and helped to built the unfinished Volga-Don canal. Similarly, G. Gruber used Kästner's textbooks during his works on the Ljubljana canal.

On 6 August 1795 T. Gruber presented a vacuum thermometer and a barometer of his own production in the letter to Ferenc Count Széchényi (* 1754, Fertöszéplak; † 1820, Vienna), the founder of the Hungarian National Library and the National Museum in Budapest. In those days, T. Gruber expected a visit of Ferenc and his wife in

Prague. T. Gruber mentioned a letter of Bohuslav Baron Hasištejnský mailed to Lobkowitz on July 30, 1795. T. Gruber also noted Johann Rudolf Count Czernin von Chudenitz (* 1757; † 1845), Sternberg, T. Gruber's friend Dr. Jan Mayer, the general František Josef Kinský and Abbé Gibling (Josef Kiblin).[1867]

15.8.5 Conclusion

Tobias Gruber' enrollment in the Masonic Lodges enabled Gruber's rapidly progressions on the Prague social networks. The Masonic Lodges socialized the most influential Bohemians, as the best part of Czechian nobles joined freemasons of those days. The freemasonic lodges were also visited by Mozart whose music was especially popular in Prague. The freemason Tobias successfully helped his brother Gabriel Gruber, who led scientific, school and diplomatic efforts to restore the Society of Jesus in Russia. As it happened to many other contemporaries, Freemasonry of Tobias Gruber was by no means in the oppositions of his love for the Jesuits. As soon as Gabriel's efforts made it possible, Tobias renewed his Jesuitical vows early in 1804 and joined the Jesuit of General Gabriel Gruber, who at that time successfully renewed the vows of the former Jesuits in Vienna, America, and China. Unfortunately, Tobias and Gabriel Gruber did not come to see the official restauration of the Society of Jesus in 1814, for which they sacrificed a large part of their powers.

The Gruber family was the true blessing for Ljubljana; it's a pity that they were Jesuits, and they did not create mathematical-technical dynasties with their descendants, like, for example, Bernoulli family! Of course, their view of useful science was not uniform, although Gabriel, Tobias and their stepfather used to be prominent members of the Carniolan Society for Agriculture and useful Arts.

At least in his later years, Gabriel Gruber's technical knowhow undoubtedly became his basic tool in gaining political reputation. Anton Gruber was a highly pedagogically oriented mathematician at a time when mathematics covered a good part of physics with vacuum devices included; Anton's hobbies were the flowers. Andrej Janez Schwindl, their stepfather, was mainly involved in agriculture. Only Tobias could at least partly be called a professional scientist from a modern point of view, but in the autumn of his life, he focused mainly on art and collecting. Despite of differences, however, Gruber's family obviously had an important common point, which was a commitment to the Jesuit order. They worked heartily to restore it and - succeeded.

15.9 Gruber on the Spread of Gases into a Vacuum

15.9.1 Introduction

Two centuries ago, the Viennese Gabrijel Gruber (1840-1805) died in St. Petersburg; he was one of the most important professors of mathematics, architecture and engineering in Ljubljana. Together with his younger brother Tobias, they wrote about many branches of natural science. They mostly observed and experimented. It is less known that they also dealt with vacuum technique in the research of the operation of pumps.

15.9.2 T. Gruber on Thermal Phenomena in Diluted Air (1788, 1791)

T. Gruber was the world's first laboratory researcher of a total reflection at the heated and colder air interface. The experiments were related to the reduction of the density of warmed air; so, he studied phenomena in diluted air. In Prague and Leipzig, he published two papers on the cooling of the gas in the lower pressure zones.

In 1788, Gruber referred to the barometric measurements of his friend, professor dr. Gerstner.[1868] Gerstner determined the height of the summits of Sudetes with his barometer. He measured in two consecutive winters. By weighing air at different pressures, he tried to prove the logarithmic alteration of density with a height[1869] according to the Laplacian barometric equation published later in 1796. Gerstner relied on the measurements of Pascal,[1870] Bouguer,[1871] Guericke, Mariotte[1872] and the professor of mathematics, state councilor Kästner.[1873] In 1866, the Celovec (Klagenfurt) professor of physics, Robida,[1874] published a slightly modified barometric equation.

Gerstner completed his studies of philosophy at the Jesuit college in his native Chomutov in Sudetenland; then he studied mathematics and astronomy in Prague. He researched in the Prague observatory and taught mathematical subjects. He established technical high schools in the German language space by founding a polytechnic school in Prague in 1806; as its director, he was inspired by the Paris École Polytechnique.[1875] He scientifically assisted the renovation of the Vltava-Danube River canal. Therefore, in 1811, he was appointed as a senior water management director in the Bohemian Lands. During the preparations for constructing the expensive canal between Vltava and the Danube near Vienna, the project was replaced by a cheaper horse-drawn railway and later by steam railway locomotives. Together with his son,[1876] he encouraged the construction of the first horse-drawn railway in the monarchy between Budweis (Ceské Budejovice) and Mauthausen; later in 1822, the rails were set up to Gmunden and Linz. It was the first railway on the European continent. Later, their program was complemented by Riepl[1877] between 1829 and 1836. On 14 September 1784, Gerstner entered the masonic lodge Zur Wohlthätigheit and he was also a correspondent member of the Zur Eintracht Lodge. Jurij Vega quoted him as a colleague scientist, and, of course, also as his freemason brother.

T. Gruber, together with Gerstner, assumed that the amount of mercury in the barometer is strongly influenced by the evaporation of water in the empty space. He believed in the theory of caloric, which freely passes through the glass of the

barometer.[1878] He described the crystallization and expansion of ice in cooling, with the assurance that air does not affect the crystallization.[1879] Similarly, G. Gruber's co-workers from Ljubljana assured that salt is not necessary for the formation of ice. Of course, later it turned out that air pressure and salt lowered the temperature of melting of ice; but this did not contradict the fact that untreated water can freeze in an empty space.

Cullen[1880] began the investigations of adiabatic phenomena of real gases while he studied the cooling upon evaporation. In a vacuumed vessel, he measured the temperature change by a few degrees when the air was pumped or drawn from the container. Initially, he was a pharmacist and a doctor, then became a professor of chemistry and medicine at the University of Glasgow. This was a very successful decision, since Cullen's student became the later famous Black,[1881] who received his doctorate in medicine in 1754. Cullen became a professor of medicine in Glasgow in 1751, and immediately after experiments with adiabatic phenomena, he took over the department of chemistry in Edinburgh in 1756. In 1766, he moved to the department of medicine, while at the same time he taught physics until 1773. He was superb teacher and taught almost until his death.

Soon after Cullen, Arnold[1882] supplemented his research on adiabatic phenomena in a vacuumed vessel. He published the discussion in his dissertation for habilitation for professor of physics at the University of Erlangen. Both Cullen and Arnold had adiabatic cooling for a basic consequence of evaporation of water. Arnold attributed the adiabatic heating to friction between the air flow and the thermometer. Lambert[1883] had already seen Arnold's experiment in 1761. Cullen's and Arnold's results were explained by changes in the density of the particles of the flame in the vacuumed vessel.[1884]

A clear distinction between Swiss-German and Scottish surveys is shown by Scotsman William Cleghorn, who linked adiabatic phenomena with the substantive theory of heat in 1779. With the same assumptions, he explained both cooling and heating. He first emphasized that the change in temperature is caused only by thickening or diluting of the gas. In 1745, Cleghorn took over the moral philosophy department at the Edinburgh University after his client withdraw the support for his rival the renowned philosopher Hume.[1885] Most researchers did not consider Cleghorn's findings. Among the few exceptions was the posthumous edition of Black's lectures in Edinburgh. Of course, Black received his PhD degree at the time of Cleghorn's death.[1886]

In 1783 Lambert's interpretation was accepted by Saussure, and Gruber read it. On 1 January 1791 Gruber investigated the phenomenon first observed at the mine pump in Schemnitz (Banská Štiavnica) in Slovakia in 1758. He certainly had his own experience as Gabriel Gruber renewed the hydraulic pump by Sava river in Kranj near Ljubljana in 1770.

On 23 March 1753, a pump was built by Josef Karl Hell (Jozef Karol Höll; * 1713 Štiavnické Bane; † 1789 Banská Štiavnica (Schemnitz)), the elder brother Maximilian Hell and Ignaz Cornel Hell. It operated in Schemnitz without a propulsion engine, driven by the difference in hydrostatic pressure. The brother Maximilian, who taught at the same time in the nearby town of Banská Bystrica, helped J. K. Hell in his calculations. Hell's pump was very well known, and the Americans used it almost a century later to pump oil in Pennsylvania.

When the compressed air from the pump in Schemnitz was pumped through the valve, snow accumulated on the valve. In the Hell's type pumping of a water column higher than 40 meters, the air under high pressure, while expanding into the atmosphere, imposed solid ice on every object along its way. The royal physician botanist fellow of RS Nataniel Mateusz Wolf from Warsaw and Jars described the phenomena among the first.[1887]

Communicated by Mr. Henry Baker, F. R. S. *Philosophical Transactions* (1761) 52: 547-554 (Wolfe's description of Hero's fountain at Schemnitz.

Initially, G. Gruber's professor of physics in Graz Poda investigated Hell’s pump and suggested improvements. Born published his Book Review of the Poda’s description. Already after 20 s to 30 s, ice was collected at the end of the tube without a physical cause,[1888] which the then learned observers could explain. In 1773, Hell’s pump from 1753 was described and drawn by Gruber's Viennese mathematics teacher Scherffer at the end of his hydrodynamic textbook for students of the Jesuit philosophical classes just before the ban of Jesuitical order. However, Poda did not care much about the formation of ice, but he investigated much more the mechanical functioning of the pump. He liked the most shut-off valves, which he drew out in detailed picture.[1889] So, in his Viennese class Scherffer acquainted both his students, Gabriel and Tobias Gruber with Hell's invention, which had a particularly heavy weight among the Jesuits because of the highest position of inventor's brother the Jesuit Maximilian Hell.

Erasmus Darwin (1731-1802), the grandfather of the famous Charles Darwin,[1890] repeated Cullen, Arnold and other experiments in 1773 and 1775. In 1784, in a letter to potter Wedgwood,[1891] he reported experiments in which the air is always taking heat from the surrounding area. Wedgwood developed his potter workshop with scientific knowledge and became the queen's potter; in 1783 he was elected became fellow of the Royal Society in London. Together with Watt, dr. William Small, Darwin, Watt's assistants Murdoch[1892] and Priestley he was a member of the Lunar Society in Birmingham. They met at the full moon to be able to return home sober in the unspoken roads until the riots, during which Priestley's house was burnt in 1791.[1893]

Before the 19th century Darwin and De Luc were the only researchers who realized that adiabatic phenomena cause compression of the air, rather than their filling of the vacuum. Therefore, they were not particularly hot for experiments in vacuum. De Luc criticized William Irvine’s (1743 Glasgow-1787) and Adair Crawford's theories. Although he was of the Swiss origin, De Luc traveled a lot and, after settling in England, he departed from the Swiss-German description of adiabatic phenomena which was contrary to the British views. Like Leslie[1894] and John Murray[1895] of the University of Edinburgh, De Luc did not distinguish between specific heat at constant volume and at constant pressure.[1896] In 1819 Leslie separated three ways of heat transfer: radiation, convection (mixing) and translation.

In the year 1784, Darwin and Fox[1897] studied cooling by sudden release of compressed air from the vessel, which caused the water vapor to freeze the air on valve of the pump in Schemnitz. On 13 December 1787, in his paper read before the Royal Society he noted that he could freeze even mercury through such a procedure. He was thinking about the cold in the higher altitude of the atmosphere, where at a lower pressure the air expanded and cooled. He described the adiabatic changes involving meteorology correctly, but his ideas did not have a big echo. He was thinking of a rocket propelled by oxygen and hydrogen fuel, of steam turbines, a multi-mirror telescope and a steam powered carriage.[1898]

Gruber and a chemistry professor at the Medical Faculty at the University of Halle, Gren,[1899] have criticized Darwin. Darwin's ideas were accepted by Scotsman Hutton,[1900] whom Darwin introduced in 1774 to the Lunar Society in Birmingham. Darwin’s views were also,

advocated by Cavallo,[1901] who became famous for testing paper balloons in 1782.[1902] Cavallo was a member of the Royal Academy in Naples, and in 1803 he settled in London. Gruber could find many Cavallo’s works in the Zois’ Library of Ljubljana.

Gruber criticized Darwin's assumptions as they did not seem sufficiently supported by experiments. He accepted Franklin's idea of the electric nature of heat transfer. He quoted Franklin's letters in their German[1903] translation, which the Jesuits of Ljubljana acquired in 1761, three years after the print. In his library, Ž. Zois had a French translation of Franklin's works, in which the translator criticized Franklin's theory.

Franklin's theory supported Saussure's experiments. Saussure's barometers of special manufacture were purchased at the same time in Ljubljana's Lyceum. Between 1762 and 1784, Saussure was a professor of philosophy at the Academy in Geneva. Between 1758 and 1779 he studied the geology and meteorology of the alpine glaciers. He first climbed to the top of Mont Blanc in 1787. His son, Nicolas Théodore de Saussure (1767-1845), explained the photosynthesis discovered by Dutchman Jan Ingenhousz (1730-1799) in Vienna in 1779 just before returning to London. Gruber cited H. B. Saussure's travelogues with the German title as he read his work in a translation that appeared between 1784 and 1796. Saussure published measurements with a special hygrometer on the hair isolated under the bell. He determined the quality of the air with the eudiometer on nitric oxide (NO), which the erudite of those times considered as the important experimental device comparable to a thermometer or barometer. He agreed with Volta that the evaporation is a source of electricity in the atmosphere.[1904]

Gruber disagreed with Darwin that mechanical stretching takes heat from the body. He considered that the dilution of caloric' fluid only affects the bodies nearby. According to Gruber, denser air does not emit heat to the surrounding area. In his calculations, he used his three-year-old measurements of boiling water's dependence on external pressure.[1905] In his study of the relationship between water vapor and air volumes, he referred to his discussion in which he described electrified clouds as thermal insulators in 1790.[1906] With the assumption of colder upper parts of the atmosphere, he explained the origin of the hail. He correctly observed that there is a similar tide in the atmosphere than in the oceans.

Darwin assumed that the mercury level in the barometer determines the pressure of the lower elastic layers of the air. The pressure is also influenced by rain, which changes the amount of acid (CO_2) in the atmosphere and the air density during the rainfall. Because of altering the altitude of mercury in the barometer at the rain, Gruber relied on his travelogue discussion, which he had just "published" in Dresden. He wrote it together with Gerstner and other colleagues for a scientific society in Prague. He illustrated his model of the atmosphere by the results of experiments with the air pump. Later G. Gruber exhibited a similar air pump at the Academy in St. Petersburg in June 1799 where it was admired by Russian dignitaries.

In Gren's concluding remarks about Gruber's critique of Darwin, Gren took Gruber's side. The publisher of both their works Gren earlier published the translation of Darwin's discussions. According to Gren, the losing of heat in Hell's pump cannot be explained by the mechanical effects of the diluted air in Darwin's way. Gren agreed with Gruber that the phenomenon is caused by the heat flux, therefore by then popular caloric.[1907]

Darwin assumed that the mercury level in the barometer determines the pressure of the lower elastic layers of the air. The pressure is also influenced by rainfall, which changes the amount of carbonic acid in the atmosphere and the air density during the falling of rain drops. Gruber relied on his travelogue discussion on the causes of changing the level of mercury in the barometer when raining.

Gren and Gruber were determinately strongly committed to gradually prevailing (Lavoisier's) theory of caloric of that time, while Darwin was more cautious about Lavoisier's caloric maybe also because Lavoisier lost his head soon after quarrels between Darwin and Gruber. Darwin might even had some nationalistic obstacles on the eve of English global conflicts with the French. Gren and Gruber believed in applied dynamic theory of Bošković or Kant and did not care much for the atoms in Dalton's networks; Gren even published a manual of physics and chemistry following the

ideas of Immanuel Kant.[1908] Gren edited the magazine Journal der Physik between 1790 and 1794, and later he edited the Neues Journal der Physik until 1798. These were the predecessors of Annalen der Physik, the leading German physics journal of the nineteenth century. Gren considered that the new Lavoisier chemistry could be combined with the older Stahl's phlogiston; Gren was therefore criticized by the opponent of phlogiston, the German of the Swiss genus Girtanner[1909] who researched and manufactured salt near Edinburgh where E. Darwin had previously studied medicine. The caloric ideas soon found their echo among the people of Ljubljana, when the governor of the Illyrian provinces Marmont initially firmly believed that he was able to weigh the caloric in his lab designed at the bishop's palace by the cathedral; the poor bishop of Ljubljana had to leave his residence, of course.

Gruber and Darwin dealt with adiabatic phenomena attracted them by their mutual interests in the meteorological phenomena. At the end of the 18th century, meteorological effects were mostly explained by adiabatic phenomena. There were few reports published in the French language. In 1790 Chaptal[1910] reported about Cullen's exploration of the air pump, but accidentally attributed its whereabouts to evaporation.[1911] The son of the pharmacist Chaptal was initially a physician and professor of chemistry in Montpellier; between 1800 and 1804, as Napoleon's interior minister, he helped to establish a new European policy along with the Jesuit general Gabriel Gruber.

In 1792, the Swiss Pictet,[1912] known for his exploring the reflection of infrared rays, investigated adiabatic phenomena in the formation of fog with the ancient Heron's overpressure reaction burner, which was also obtained by the Jesuits of Ljubljana in 1755. According to the theory of caloric, Pictet considered that heat was excreted from gas similarly as water from the mushroom. He was Saussure's disciple and friend and took over his chair of philosophy at Geneva University.[1913] Pictet was a close friend of Count Rumford,[1914] just like the Carniolan Jurij Vega. Pictet also collaborated with the friend of Žiga Zois, Déodat de Dolomieu.

Delamétherie took over the editing of the influential Journal de Physique, founded by Abbé Rozier[1915] in 1772. Delamétherie published Pictet's ideas there, although he misinterpreted and misunderstood Pictet's results, so that he believed that the cooling can be enhanced by adding smaller amounts of water to the vacuumed vessel. Like Chaptal, Delamétherie believed that an adiabatic cooling was a phenomenon the evaporation of the ether; but he failed and did not consider Pictet's assumptions. Delamétherie was a descendant of an important French family from La Clayette of eastern France, and he took over the chair of natural science at the Parisian French College in 1800.

Delaméterie's mistake was repaired by the mining inspector Arsène Nicolas Baillet, who taught at a mining school in Paris. In two parallel reports, Baillet realized and recognized the significance of Pictet's discovery and linked it with the descriptions of the mine pump in Schemnitz, today's Banská Štiavnica. He accepted Adair Crawford's[1916] (* 1749; † 1795) assumption of increasing gas capacity by reducing its density.

A young German poet and novelist Ludwig Achim von Arnhem (* 1781; † 1831),[1917] summed up the achievements as a student of mathematics in Göttingen. He advanced his ideas by the research of his predecessors on the expansion of gases into a vacuum. The former priest and the Jacobine Jacques Michel Coupé tried to explain adiabatic phenomena of recent sudden frosts and fires in France, much like Darwin before him; the global cooling/warming is therefore not just a flurry of today. Mollet (* 1756; † 1829)[1918] from Aix, a professor of physics at central schools, later at the

university in Lyon, has rarely quoted Coupé's research. The French were not much interested in adiabatic phenomena until Laplace and Biot used it to obtain the important physical results by of calculating velocity of sound in the air in 1802.[1919]

Dalton[1920] with his precise experiments, again unveiled the entire Pictet's problem. According to the principles of Black's student Glasgow professor Irvine,[1921] supplemented with the theory of caloric, Dalton explained the higher temperature in the empty space by the greater specific heat of the vacuum which seemingly dwarfed the specific heat of the same volume of air. That presumption was refuted by the incorrect measurements of Delaroche[1922] and Bérard[1923] in 1812, which was mistakenly awarded by the Parisian Academy.[1924] Their error was investigated by the research of specific heats of the Poljane native Simon Šubic, who was the first among Slovenes to publish about the dangers of explosion of steam boilers. Šubic learned about that problem already at home, since the first steamer in the Slovene ethnic territory had been tried in Trieste in 1818, and a dozen years later, the Bohemian German Josef Ressel (* 1793; † 1857) experimented with a screw locomotion to amuse the folks in Trieste.

15.9.3 *Specific Heat of the Caloric Theory*

The specific heat is more difficult to measure in gases than in droplets of fluids or in solids. The first major measurements were published by Crawford in 1779 and 1783. He exhausted one of his brass vessels, and in the other he left air. The containers were heated and immersed in the same calorimeter. He measured the temperature of the calorimeter and thus determined the specific heat of the air at a constant volume. The result was only 3% higher than the modern one. However, the brass container had a much larger mass than the measured gas, so the accuracy of the measurement was not high.[1925]

So, Crawford's measurements were not taken seriously until Dalton analyzed them in 1808 and 1842. Dalton combined Irvin's theory of the proportionality between specific heat and the heat contained in body with Dalton's own theory of caloric, which was otherwise foreign to both Irvine and Crawford's way of thinking[1926] because Irvine was more an industrial chemist and owner of glassworks far from Dalton's theoretical speculations. Crawford considered that his measurements confirmed Irvine's theory published by Irvine's son also named William (1776-1811).

The ice calorimeter was assembled by Lavoisier[1927] and Laplace in winter 1782/83 and they equipped it with instructions for determining the specific heat of the gases. Their measurement of specific heat of air at constant pressure exceeds the modern value by 36%.

Crawford, Lavoisier and Laplace did not distinguish specific heat at a constant pressure from that at a constant volume at the end of the eighteenth century. In the last years of the first empire, the French researchers have already known the difference. They were especially interested in the influence of specific heat on the speed of sound. Hence the prize of the French National Institute, which in January 1811 promised 3000 francs for:[1928]

"The determination of specific heat of gases, especially oxygen, nitrogen and some composite gases, and comparison with the specific heat of water(...)"

The prize was to be awarded in 1813. Two important discussions were submitted. Clément[1929] and his later father-in-law Désormes[1930] were not rewarded (because they failed to compare their results with specific heat of the water. In their paper, published only in 1819, they complained as victims of a certain scientific policy, which was not far from true situation during the reign of Laplacian school. However, they had a factory in Verberie in Oise department 79 km north of Paris

[1929] Nicholas Clément (Clément- Désormes after his marriage in 1820, * 1779 Dijon; † 1841 Paris).
[1930] Charles-Bernard Désormes (1777 Dijon ; † 1862 Verberie).

and a teaching posts in Paris, so they were not really threatened up with any hunger by their unjust compatriots.

In fact, Clément and Désormes’ measurements contradicted the fundamental principles of Gay-Lussac's[1931] work in recent years; of course, this could not have been without consequences. Instead of the assumptions of the Laplacian Circle advocated Dalton's Irvinist theory and opposed its later victorious rivals of Delaroche and Bérard whose father worked with Chaptal.[1932] The inclinations of both couples were different because Delaroche and Bérard were more naturalized Parisians and more involved in biological researches. Clément and Désormes’ closed the container full of air associated with the water gauge and the vacuum pump. They reduced the pressure in their container by about one centimeter of the mercury column, that is, to 0.987 Pa. They briefly opened their valve so that the outer and inner pressures were offset. Then they shut their valve. The closed gas gradually lost heat. The gauge measured the pressure drop of the locked gas, which determined the increase in temperature during the opening of the valve.

In the second part of Delaroche and Bérard’s experiment, the gas bottle was poured into the calorimeter so that the gas was stretched towards the water gauge. The elongation measured the specific heat of the gas at constant pressure. With a slightly modified process, the relative specific heat can be measured at three different pressures lower than the normal pressure.

From the first experiment, Clément and Désormes could calculated specific heat at a constant volume. If T_2 is the outside temperature, T_1 is the temperature of the vessel after the they closed their valve and the pressure equalized with atmospheric pressure p_1,

$$T_1 = (C / c) T_2$$

If the final pressure p_3 is measured with the gauge, the ideal gas equation applies:

$$p_1 - p_3 = = (R \rho/M) (T_1 - T_2)$$

$$C - c = R/M$$

$$c = (\rho T_2) (R/M)^2/(p_1 - p_3)$$

Thus, Clément and Désormes measured the specific heat at a constant volume and at constant pressure. In this too they differed from Delaroche (1813), for whom, Crawford's specific heat did not seem to be “a specific heat in the sense as it is (usually) given to this word in a constant volume, since such closed gases cannot expand, ~~note~~ could they liquefy”.[1933] Half a century later, the approach was completely changed since Clausius[1934] had specific heat at a constant volume (c) for the "wahre (Wärmecapacitat)" therefore for the real one.

The award was given to Delaroche and Bérard for their measurements of specific heat from 1812 published the following year. Their results contradicted Irvin's theory, much like Dulong[1935] and Petit’s[1936] findings on the inverse proportionality of specific heats and atomic masses of metals from 1819. Similarly as Delaroche and Bérard, also the other couple Dulong and Petit stated that the measurements do not confirm the proportionality between changes in specific heat and the absorption or emission of heat during chemical reactions.

Then, the specific heat, of course, is not proportional to the heat contained, as predicted by Irvin's theory in the Dalton version, which was based on caloric. Both caloric theories, Dalton’s Irvinist and Delaroche-Bérard’s, also had common points. Both predicted that the vacuum had a higher specific heat than the air of the same volume. Delaroche and Bérard explained the results of their measurements by decreasing the specific heat by lowering the pressure, as the caloric easier penetrated an empty space.[1937]

Until the measurements of Regnault[1938] published in 1853 and later, the claims of Delaroche and Bérard specified the mainstream reflections on the specific heat of the gases. The misinterpretation of their results thus led astray a whole generation of researchers.

Gay-Lussac in Welter		1822	Unpublished	C/c	Air	1.3748	Laplace 1823
Regnault		1853, 1862	flow calorimeter	C	Various	0.2377	Clausius 1862
Contemporary results						C=0.2420 c = 0.173	

Let's look at the more details of measurements of Delaroche and Bérard. The modern reader should note that the number of published decimal places in their results greatly exceeds the accuracy of their measurements. This was exactly in line with the then practices in physics, but today, of course, it sounds very strange.

In the Delaroche and Bérard device designed as a flowmeter, a constant mass flow of gas with constant pressure and temperature T_1 in a calorimeter was flowed through the tube and drained with temperature T_2. In addition, the calorimeter was heated from the temperature T_3 to the temperature T_4. We get:

$$m_g \cdot c_g \cdot (T_1 - T_2) = m_a \cdot c_a \cdot (T_4 - T_3)$$

Index g refers to gas, while index a designs water in the calorimeter.[1939] According to this equation, the specific heat of a gas at a constant pressure (c_g) was determined. Delaroche and Bérard investigated the specific heat dependence of the gas density. They prepared the experiment so that the air could run into a calorimeter at two different pressures. The first measured 0.974 bar, while the other measured 1.322 bar. They only published two measurements; for both, the specific heat at a higher pressure was greater in the ratios 1: 1.2127 and 1: 1.2665. Since the pressure is in the ratio 1: 1.357, the gas must have a smaller specific heat at a higher pressure. The specific heat was reduced by a ratio of 1: 0.913 with a pressure increase.

The result of Delaroche and Bérard differs by less than 10% from modern measurements. Today at

1939 Mach, 1919, 196.

such a small pressure interval we expect a barely perceptible decrease in the specific heat of the gas. The error was not great, but it had fatal consequences. The result of Delaroche and Bérard was in line with the expectations of the then theory that the compression of a substance hinders the penetration of the caloric into the space between molecules. This theory was also advocated by the leading French researcher Laplace, who used the wrong results of Delaroche and Bérard in his theory of the speed of sound in 1816. The Laplacian theories were extremely influential and, according to his predictions, they even adjusted the results of the measurements, just like in the modern climate change hoaxes.

The Parisian Institute's prize was such an important decoration that the Delaroche and Bérard's measurements were not seriously examined for more than three decades, although other theories and experiments offered completely opposite conclusions about the nature of specific heats of gases.

The results of Delaroche and Bérard contradicted the theory of the Poisson,[1940] velocity of sound determined in 1808 and measurements of the ratios between the specific heats of Gay-Lussac and Welter. Gay-Lussac and Welter[1941] did not publish details of their technique of measurements in 1822, but they probably resembled the ideas of Clément and Desormes. Their results were used by Laplace in 1823 in his new theory of sound.

The results of Delaroche and Bérard were kept afloat even longer than the caloric theory that did not survive the middle of the 19th century. They were the basis for many theoretical considerations. Even in 1816 in Paris Biot was convinced that the previous measurements were not precise enough to establish a convincing theory about the ratio between the specific heats of the gaseous compound and its components ("dei gaz componenti e gaz composto").[1942]

In 1816 and 1817, the Torino professor Avogadro[1943] in Milan published such a theory. He analyzed the measurements of the specific heat of the various gases published by Delaroche and Bérard in addition to the described measurement.

Despite of the large deviations in some cases, Avogadro believed in the validity of the equation:

$$(c)^2 = \Sigma\, p_i \cdot (c_i)^2$$

where we would now write the Avogadro's symbol c used for "calore specifico riferito al volume" as:

$$c = c_p \cdot \rho/(c_p(\text{air}) \cdot \rho(\text{air}))$$

The quantities with the index "i" refer to the components of the compound, and the weights pi are the relative volume proportions or the relative number of molecules of the individual elements. Thus, for carbon monoxide CO, which forms carbon dioxide CO_2 with oxygen O_2, it would be:

$$(c \cdot \rho \cdot (CO))^2 + (1/2) \cdot (c \cdot \rho \cdot (O_2))^2 = (c \cdot \rho \cdot (CO_2))^2$$

A similar equation was written by Dulong in 1830.[1944] The modern measurements show that in the case of carbon dioxide the sum on the left is 20% smaller than the right side of the equation. With the Avogadro equation for specific carbon dioxide we get the following results:

$$(cd\,(CO))^2 + (1/2)\,(cd\,(O))^2 = 1.3\ 10^6\ (J / (K^3\ m^2)$$

$$(c\,d\,(CO_2))^2 = 1{,}6\ 10^6\ (J/K^3\ m^2)$$

Avogadro's affinity for caloric ("Affinita per calorico", a) for gases:

$$a = (c^2 / d)$$

where:

$$d = \rho / \rho\ (\text{air})$$

is even a more interesting one. From the written Avogadro's equations, it follows that the affinity for caloric in the compound is equal to the sum of the affinities of its components:

$$a_i = \Sigma\, a_i \cdot v_i$$

v_i are the weight proportions of the elements in the compound. A similar equation is used today, only

[1940] Denis Poisson (* 1781; † 1840).
[1941] Jean Joseph Welter (* 1763; † 1852).
[1942] Avogadro 1816/17, reprint 1911, 106.
[1943] Amedeo Avogadro (* 1776; † 1856).
[1944] Avogadro, 1911, CXV.

Avogadro's affinity for the caloric "a" should be replaced with specific heat. Avogadro wrote an equation that links the physical and chemical properties of gases:

$$c = (a \cdot d)^{1/2} = K \cdot (m \cdot a)^{1/2}$$

m is the mass of the molecule, and K is a constant. Avogadro's hypothesis from 1811 can be derived from the above assertions. In 1816/17 Avogadro did not deal with specific heat at a constant volume. They were not yet able to measure it directly, but it can be calculated from the velocity of sound according to Poisson and Laplace's theory. However, Dulong only published useful measurements for one-atomic gases; Avogadro used them in the third part of his most comprehensive Fisica dei corpi imponderabli in 1838.[1945]

Even the famous Carnot[1946] was uncritical to the measurements of Delaroche and Bérard, although he was also influenced by their opponent Clément. Delaroche and Bérard's incorrectly measured dependence of the specific heat of the air on the pressure. In Carnot's later famous booklet, that error was extended to the pressures between 1/1024 and 1024 bar in 1824.[1947] According to Carnot, the specific heat of the air is reduced by as much as 11.5 times in this pressure interval! Only twenty years after the publication of Carnot's book Johann August Natterer (1821-1901) reached such high pressures! In April 1844, during his medical studies in Vienna, Natterer predicted that he would investigate gas pressures at a pressure of up to 2000 bar. In November 1850, Natterer described his first experiments at 1000 bar. There are so many pressures which Carnot discussed a quarter of a century too early in the year 1824. With the financial support of the Viennese Academy and with the participation of a correspondent member of the Academy elected on 1 February 1848, the zoologist and Doctor of Medicine Ludwig Redtenbacher born in Kirchhoff in 1814, Natterer already reached 3600 bars in 1851. Three years later, Natterer published accurate measurements of five different gases at pressures of up to 2790 bar, as also reported by Andrews. Ludwig Redtenbacher was the second cousin of researcher of Dynamide Jacob Ferdinand Redtenbacher [1948] and a brother of Josef Redtenbacher (* 1810).[1949] Jacob began his research as an assistant to Arzberger, who studied running water and ships for mechanical engineering at the Viennese Polytechnic Institute.[1950]

With the general recognition of the results of the measurements of Delaroche and Bérard, researchers gave a decisive blow to Irvin's theory. Dalton gave up Irvin's theory only in 1827, when he himself repeated the experiments of Delaroche and Bérard.[1951] Both contradictory theories remained in the range of the preservation of caloric. In the early thermodynamics, the researchers finally rejected the caloric itself.
The first experiments which tried to disprove the conservation of caloric were published by Count Rumford in 1781 and 1798 and by his protegee Davy.[1952] Both were closely linked to the beginnings of the Royal Institution, which could have affected the related negative attitudes towards caloric intake of both researchers. They were Anglo-Saxons, while many basic facts about caloric belonged to the beheaded Frenchman Lavoisier.

In those times the term 'permanent' was used for the modern idea of 'ideal' gas. The scientists argued that oxygen, nitrogen, hydrogen and some other gases cannot be liquefied at all. The first doubts in Delaroche and Bérard's experiments did not appear until 1850, at the same time in ideas of three researchers: Joule, Rankin and Clausius. At the beginning of his experimenting, Dalton's disciple Joule[1953] came to the idea that heat can be expressed in units of work. But his experiments at

[1951] Fox 1968, pp. 191 and 196. Dalton's record from June and the year 1800 (Fox, 1968, 191) describes the variant of Irwin's theory, according to which the vacuum should have a greater specific heat than the air of the same volume. This conclusion did not contradict Delaroche and Bérard's assumption that, by reducing air pressure, its specific heat increases, as the specific heat supposedly increases with volume.
[1952] Humphry Davy (* 1778; † 1829).
[1953] James Prescott Joule (* 1818; † 1889).

first did not convince either William Thomson[1954] or Helmholtz, though both were inclined to relate to similar ideas.

Based on the vortex theory of molecular structure, the Scotsman Rankine[1955] conceived heat as the motion of material particles. Nevertheless, he refused to consider Joule's experimental results and calculated the mechanical equivalent of heat from the measurements of the specific heat of the air at constant pressure. He used the measurements of Delaroche and Bérard like Mayer[1956] did eight years before. Rankine's calculation of specific heat of air was in accordance with the measurements of the Regnault's Group, which were published three years later. Clausius made theoretical findings before the experiment in 1850. He argued that in the "permanent" gas both specific heats must be independent of the pressure and temperature in contrast to the measurements of Delaroche and Bérard.

As early as 1824 Carnot knew that the difference between the specific heat was constant. Poisson, Gay-Lussac and Welter have found thatratio of the specific heats is constant. In his theory, Clausius merely linked both findings.[1957]

The last doubt disappeared with the measurements of the Regnault's Parisian group published in 1853. They used Delaroche and Bérard's measurement methods from 1812; but their result was completely different. The specific heat of the air remained constant at pressures between 1 and 7.465 bars. Regnault has proven that the specific heat of "permanent" gases does not change with temperature. It would, therefore, be very interesting to know how Laplace and colleagues would research within their theories of the caloric if someone half a century before Regnault tried to make a similar group of precise experiments to determine the properties of gases.[1958]

According to the high-profile tests of the Regnault's group, it was shown that the increased pressure does not impede "penetrating heat into the substance". The research on heat rays has also contributed to the abandonment of the theory of caloric.[1959] It was already known in Europe after William Herschel's experiments proved that the rays of heat had the properties of light in 1800.

When, in the early 1820s, wave theory became established in optics, many tried to expand it into the theory of heat.[1960] The heat was conceived as a kind of movement, which in the second half of the 19th century could be already based on the law on the conservation of energy. This law is at odds with the theory of caloric preservation, as it predicts the reduction of heat by the motion of visible bodies. The new theory of heat strengthened, while the old theory gave it its space.

The heat theory that gradually supplanted the theory of caloric is called thermodynamics. The name "Thermodinamik" was first used by the later president of the Viennese Academy, Baumgartner, in a book published for the first time in 1837.[1961] The new name became soon known on Habsburgian soil, because Baumgartner's book was used as a textbook of physics at gymnasiums in Ljubljana and Klagenfurt even in the 1860s. The term "thermodynamics" was adopted by W. Thomson in 1851.

By the analogy with optics, the wave theory of heat was able to pass from the theory of caloric to modern theories. It alone did not offer a convincing model of forces and particles of matter with which it could replace caloric. For this reason, the idea of moving and mutually colliding particles of matter has gradually become established.

The idea was by no means new. Daniel Bernoulli (1700-1782) described in 1738 the theory of motion of molecules of matter as the only acceptable theory of heat.[1962] For the researchers such as Lavoisier and Laplace in 1783[1963] and Lamé[1964] in his textbook of 1836, this description equalled importance of the theory of caloric.

The kinetic theory in modern terms became a valid physical theory only after Krönig's paper in 1856 and Clausius' publication a year later. The first

researchers of the new theory, including Poljane native S. Šubic,[1965] were mainly focused on gases as a model for both other two aggregate sates.

15.9.4 Joule-Thomson Cooling

K. Hell's and R. Gruber's early experiments were developed by the Brits, the French and the Germans. In Britain, they were first complemented by Cullen and Darwin, followed by Dalton, Joule, Thomson, Dewar,[1966] and finally Linde.[1967] In France, Jars reported on Hell's experiment, and then, as Leslie's critique, Humboldt and Gay-Lussac continued to research, and finally there was a good old sceptic positivist E. Mach.

Four decades after Dalton, his study of adiabatic phenomena was supplemented by his disciple Joule, a brewer from Manchester. By the time of his bankruptcy in 1854, Joule was the third generation of brewers, and his father had to set up his laboratory next to the factory. In 1843 Joule began to explore the expansion of gas in a closed system. The pressed gas adiabatically flowed from its vessel through the valve into the second empty tank. Joule described the experiment as the expansion of air into a vacuum without work and without any added heat. Internal energy and temperature remained unchanged.

In 1844, Joule knew Cullen, Darwin and Dalton's work, but Gay-Lussac's[1968] experiments at Bertholet's Arcueil Laboratories (1801) remained hidden to Joule, who therefore repeated them. Gay-Lussac encouraged Leslie's wrong assumption that all gases had the same thermal capacity; this was the time when erudite Europeans barely started to distinguish individual gases from each other. The ancient term air as the designation of all gases was only slowly abandoned after it became clear that the air itself is a conglomerate of several gases. Gay-Lussac used two bronze containers of capacity of 12 l and two apertures. His thermometer precisely showed up the temperatures up to a hundred degrees Celsius. At first, Gay-Lussac used a thermometer according to the ideas of Rumford and Leslie, and later arranged a less sensitive thermometer filled by alcohol. He concluded that, in the case of a better vacuum, more heat is released from the intrusion of the surrounding gas. Therefore, he wanted to find the connection between the heat absorbed in one container and the heat freed in another vessel. He was also interested in the dependence of temperature differences on the density of the air. He proved that the lighter hydrogen spreads faster into vacuum than other gases.[1969]

Joule attributed first quantitative experiments to his teacher Dalton's expansion of gases into a vacuum; with them Dalton supposedly denied the material nature of heat.[1970] In 1853, Thomson watched the penetration of air through silk. They used a double piston compression pump, a cylindrical piston with radius 4.5 inches, and its working stroke length of 9 inches. At sixty full strokes per minute, the pump can remove about 16,000 cubic inches of air every 16 minutes. Due to the mechanical piston, the losses caused by leakage were of course large; so, they never used more than half of the available power.[1971]

The present researchers today know those events as Joule's or free expansion. Joule attracted the Scotsman W. Thomson to more exact experiments in the open system; together they studied Joule-Thomson's cooling. However, it could not be clarified until the Irishman Andrews and the Dutchman van der Waals[1972] reported that gas propagation is being carried out against attractive forces between molecules. Therefore, the temperature changes.[1973]

The cooling by the expansion into the empty space was also studied by Ježica native Karel Robida.[1974] His example used to illustrate the mixing of two gases was resembling the attackers, who were shooting the crew of the fortress. In the Joule-Thomson experiment, gases cool when propagated into an empty space. Therefore, there is certainly an attractive force between the gas particles which decreases and cools the gas by increasing the distance between particles.

Most gases are cooled at normal temperatures while expanding into an empty space. Some heat up, including hydrogen and helium. Adiabatic cooling of gases with the expansion into an empty space became useful only with Faraday's condensation planed for all gases; even those gases which until then were considered permanent. It turned out that the propagation of gas into an empty space is the most appropriate procedure for its cooling. It was used for the liquefaction of air, hydrogen and helium in the last quarter of the 19th century. Today it is used in all domestic compressor-type refrigerators. It is also interesting for exploring the microscopic properties of real gases. In all these modern technologies, we see the consequences of experiments of Tobias Gruber.

15.9.5 Conclusion

The brothers Gabriel and Tobias Gruber were among the leading researchers in the Habsburg Monarchy. They also left their seals on the investigations of the cooling of gases while propagating in a vacuum. They discussed and even quarreled with the most important contemporaries, pulled out sometimes with the right and second time again with the wrong side and thus celebrated Habsburg or even the Carniolan physics far beyond Carniolan geographical borders.

The measurements of Delaroche and Bérard used to be the example of experimentalists mislead by the theorists. As the fatal consequence, those experimentalists mislead the next generation of the theorists and so on, until the changed opinion of theorists demand more money for the more accurate experiments which, as was expected, proved the initial experimental error of the Genevan physician-botanist turned Parisian Delaroche (François-Étienne de La Roche) and Bérard attached to the Laplacian Berthollet’s Société dArcueil. The process ramped almost a half of a century! Who is to blame for the misleading misinterpreted facts? Hardly anybody. We are all and we always were the victim of the propaganda in media which tells us what is right and what is wrong and even what to buy and what to abandon. The top mainstream scientists are just the humans and therefore victims of the same politics which they themselves help to establish. The victory of Laplacian Napoleonic caloric theory over the Jesuitical Ancien Régime Stahl’s phlogiston was abolished after the spring of nations of 1848.

15.10 Vacuum Becomes Part of the Electrical Industry

15.10.1 Vacuum Devices of the First Professor of Physics in Slovenia, Who was not a Member of the Monastic Order (on the 250th Birthday of Neumann)

The Parisian revolutionary battles which guillotined Maria Therese’s daughter quickly affected the Viennese, while the peripheral Ljubljana ex-Jesuitical experts enjoyed some delays. The era of Gruber and the Jesuits of Ljubljana completely ended only after the arrival of Johann Philipp Neumann (* 27 December 1774, Třebíč (Trebitsch, Trebiž), north of Vienna, west of Brno in Moravia, † 1849, Vienna). He came in Ljubljana immediately after completing his studies at the Viennese Law School. Despite his early interest in vacuum techniques, he could not immediately take over the Department of Physics in Ljubljana. His legal were not surprising, since the choice was then reduced to the studies of theology, law and medicine. First, he taught Greek language in Ljubljana for two years instead of John Nepomuk Morack (Morak, Morach, * 2 September 1730/31, Ljubljana; SJ 28. 10. 1748; † 9. 1. 1807, Radomlje) until the illness and death of Ljubljana physicist Jernej Schaller (* 24. 8. 1745; † 29. 4. 1803, Ljubljana) opened Neumann’s way to the desired department. Neumann then lectured for a few months as a substitute professor of physics and edited a rich collection of three hundred and nine vacuum and related devices left by Schaller and the mathematician Anton Gruber.[1975] With his demanding repairs for the maintenance of many vacuum pumps, Musschenbrock valves and Magdeburg hemispheres, the notorious Neumann's talent for the order was already revealed, which was later upgraded with three decades of his librarian’s work at the Viennese Polytechnic. The

editing of their library was already accomplished by his senior manager, Franc Wilde, who was also the first to be concerned about the progress of vacuum techniques and related disciplines of those days. In doing so, Neumann was helped by his knowledge of many languages: Latin, Greek, German, French and Italian. He also knew some Slavic languages, including, of course, the Czech language of his homeland.[1976]

Figure 15-56: Last Schaller's signature under J. K. Kersnik's assessment of students of physics and mathematics; in the latter, Schaller replaced the resigned Anton Gruber. The document was given by Wilde's directorship on 6 April 1803, three weeks before Schaller's death (ZAL SI LJU 184/1, box 75, p. 453).

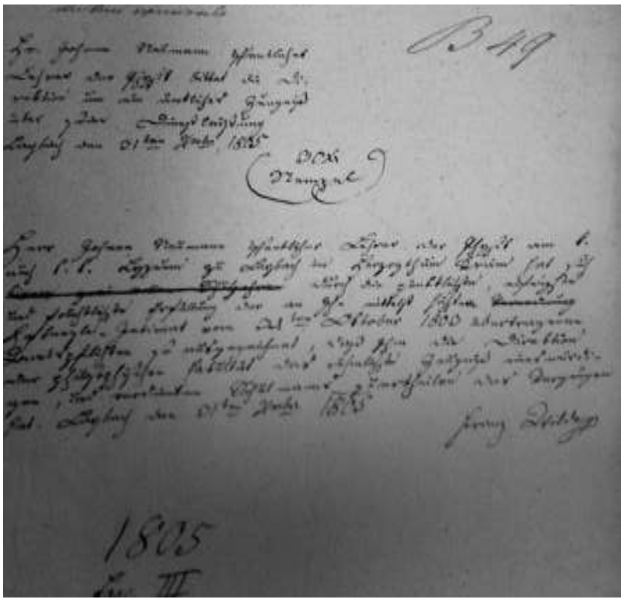

Figure 15-57: Neumann's application for the official certificate of the Ljubljana professor of physics, signed on 21 December 1805 by F. Wilde (ZAL SI LJU 184/1, box 79 fasc. 470)

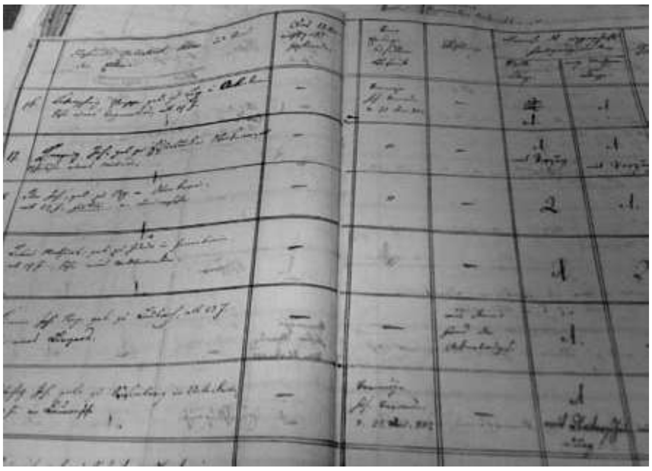

Figure 15-58: On 28 August 1803, Neumann and M. Kalister assessed the future professor of physics JK Kersnik with the highest marks in physics and mathematics in his second semester of physics and applied mathematics (ZAL SI LJU 184/1, box 75, Fasc. 453).

15.10.2 Neumann's Ljubljana Predecessors

With the death of Jernej Schaller, nearly exactly one hundred years of Jesuit physics in Ljubljana ended. After A. Gruber's sudden departure, Schaller also took over the teaching of mathematics for some time. The gradebooks of Schaller, Wilde and A. Gruber's Ljubljana students of physics with chemistry, philosophy and mathematics are preserved. The lists include tables with the student's names, places of birth, ages, grades in physics and mathematics and overall learning success. Documents were usually signed by the professor of physics, the professor of mathematics and by Franz Wilde as director. On 15 July 1791, Gruber and Schaller had twenty students; among the eight listed on the first page was also the later professor of Ljubljana, then seventeen-year-old Franc Hladnik from Idrija. On the other second page, another twelve students were enumerated. The list was authenticated by Wilde as a teacher of philosophy on 22 July 1791. The first two guys noted among the students of the philosophy and physics were the Counts Turjaški (Auersperg), Karl and Josef from Ljubljana. They were 17 and 16 years old. Both had a Tertiary scholarship (Stiftung). They did not get grades from chemistry-physics, while they had the best grades (mark one of those times) in philosophy and

[1976] ZAL SI LJU 184/1, box 52, fasc. 166, lists of professors dated on 8. 2. 1804 and 11. 11. 1806. Morack lectured on 8 September 1801, on 24 December 1801, the chair was formally vacant, although Neumann lectured on July 21, 1801; at least he already took it over officially on 8. 9. 1802.

elementary mathematics. In third place, the Lower Carniolan (Dolenjec) Leopold Baumgartner of Poganjice got his mark in physics; Johan Count Brigido, born in Lvov of then Habsburg Polish

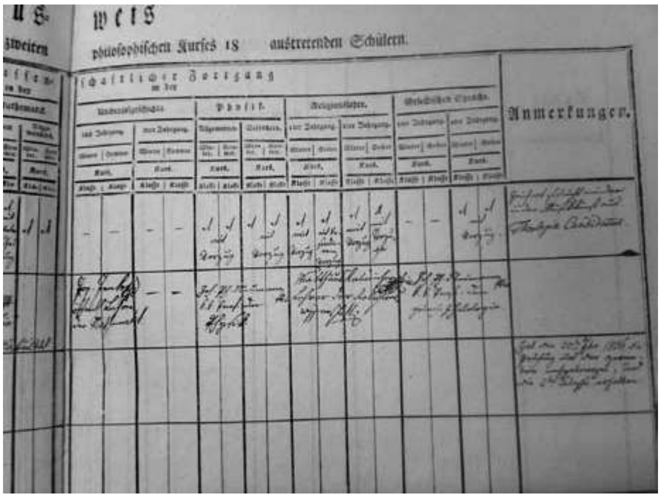

Figure 15-60: Last Neumann's Ljubljana signature under physics and Greek language grades of his students in a gradebook dated on 20 September 1806. Those students attended the first philosophical course in the first and second semesters. To the left of Neumann is the signature of mathematician J. Jenko, who also evaluated the students of general history (ZAL SI LJU 184/1, box 86 fasc. 515).

Galicia, was also listed in physics class,[1977] while the note was signed by Wilde on 6 September 1792. Similarly, it was also with students of mathematics[1978] where both counts Auersperg had also the highest marks "one" in geometry and trigonometry. Anton Gruber signed the document on 27 August 1792. This was followed by a list of the students of trade school (Krämer) in Ljubljana in 1789/90. In the days from 16 to 24 August 1792, the professors compiled another gradebook filled with marks for the students of physics in Ljubljana. Peter Garzarolli (von Thurnlackh, * 25 June 1774 Trieste; † 1846, Trieste) was noted on the first place as the eighteen years old teenager. He became a city physicist in Trieste in 1819. He was followed by a 17-year-old Leopold Count Hohenwart. The document was signed by Schaller on 27 August 1791. A. Gruber signed the marks of sixteen students of mathematics on August 27, 1792 designed three days earlier on August 24, 1792. On 6 September 1792, the gradebooks for Garzarolli, Hohenwart and their classmates were signed by the student of theology, Josef Matija Robič, who was employed as a magister repeater on the specialization.[1979] Robič was born around 1770.

On March 28, 1801, Georg Jonke (* 1777, Gorenje (Obern) No. 4; † 1864) from Kočevje was enrolled among the students. Their gradebook was signed by Schaller and A. Gruber; Jonke later became an established beekeeper, the Črmošnjice parish priest and a local mayor during the French Illyrian provinces. A. Gruber has last signed under the curriculum of gradebook with marks on 20 April 1802 and 24 August 1802. On 6 April 1802, Schaller signed as a professor of physics and a substitute (suplent) teacher of applied mathematics, and on August 27, 1803, under the gradebook full of marks Wilde and Matthias Kallister signed; the latter as a teacher of the 4th (grade) of Normal Elementary school and substitute (suplent) teacher of mathematics at Lyceum. On May 29, 1804, Josef Jenko was signed as a teacher of mathematics. On the same day, on 6 April 1804, and again in October 1804 Johan Neumann signed as a teacher of physics with chemistry, and a lecturer in Greek literature and grammar.[1980] Jenko

and Neumann lectured together in Graz again a decade later.
The repair of models and machines for physics with chemistry lessons was listed on 16 June 1800. Under no. 4638 Zollmann described a new mechanical school on 26 July 1800.[1981] On 13. 4. 1802 under the number 88/12 Wilde signed the act for the re-establishment of the Ljubljana Mechanical School; he described the lectures of mechanics and statics, and the additional work of the adjunct professor. On November 2, 1802 under number 262, in red color marked as B 22, Wilde signed the material for the school session designed for the provisional corollary supplement of the lectures of dogmatic by Matija Ravnikar and of mathematics by Matija Kalister was the library penman (scribe). The full professor of physics (Schaller) coordinated the lesson of the mathematics of the less experienced substitute professor Kalister's curricula. Anton Gruber terminated his lectures between 24 August 1802, when he was signed for his last time, and 2 November 1802, when Kalister was already mentioned as a substitute (suplent) teacher.

On 27 October 1802, under the number K 144, eighteen years old captain-Hauptmann's son Joseph Safshman, a student at St. Julius, probably at Julius-Maximilians-Universität Würzburg which recently abandoned its strict Catholicism, applied for the competition for the professor of mathematics in Ljubljana. He mastered the Latin and Slavic languages, and he had five classes of gymnasium teachings behind him. On 6 November 1802, under no. 6483 the priest Matija Kalister was listed as the substitute (suplent) teacher of dogmatic (sic!) and a mathematician while he signed himself as a physicist.[1982] The mishmash of titles testified about the troubled era of Ljubljana school in those days. On 30 April 1803, Wilde reported Schaller's death, which occurred on the previous evening at half past eight due to severe fever as a side effect of rheumatism.[1983]

15.10.3 Ljubljana Physics

The long-standing Neumann's wish was fulfilled by his takeover of the department of physics and cabinet of physics, full of popular vacuum devices. Of course, everything did not go smoothly and quickly. Prior to the official take-up of that chair, Neumann had to pass through a long exam proving his knowledge about characteristics of bodies, free fall, Archimedean law and colors of bodies that are not transparent. For the additional point, the exam continued with a written work on the correct installation of the lightning rods, and the advantages of Copernican astronomy based on the interplanetary vacuum. The exam questions did, of course, sound somewhat outdated to contemporaries as they were compiled by a friend of former professor Gabriel Gruber and his brother Tobias, Joseph Walcher (* 6. 1. 1718, Linz; SJ 18. 10. 1737; † 29. 11. 1803, Vienna). Walcher had advanced age at that time; he was more than half a century older than the only candidate Neumann who, of course, won the competition after his successful exam.

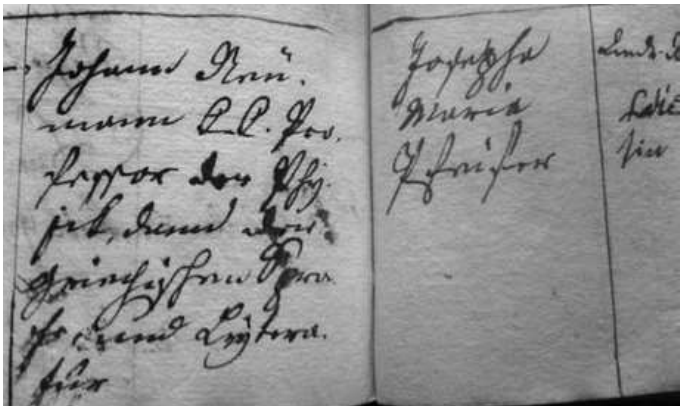

Figure 15-61: A record of Neumann and his wife Josepha Maria born Pfeifer at the baptism of their son the future physicist August Emanuel Neumann in the Ljubljana cathedral on September 27, 1804 (NŠAL Baptism Book of St. Nicholas Ljubljana, p. 28)

15.10.4 Graz and Vienna

Neumann's lessons in Ljubljana lasted only five years, since he signed the last certificates in August 1806 after he has already received proof of his Ljubljana service years during the previous years. Thus, in the autumn of 1806, he was already in Graz, at a similar higher education institution with a much longer internship, which was expecting promised transition to its former university fames. The longtime professor of physics in Graz, Gottlob Leopold Biwald (* 1731, Vienna; † 8. 9. 1805, Graz), died in the previous

[1983] *Gestern Abend… an eine Schlecht Fieber mit Rheumatische Seitenstecken.*

year, so Neumann took over his chair and a cabinet of physics, perfectly equipped with vacuum devices. In Graz, soon again, Neumann's first-class talent for administration began to surface, and he took over the rector's stick in 1810/11.

Neumann remained in Graz less than a decade. He did not feel bad, so his younger Franconian friend Johann Joseph Prechtl (* 1778, Bischofsheim; † 1854, Vienna) soon became attentive to Neumann's talent for conducting higher education. During Neumann's lecturing in Ljubljana, Prechtl served as the local teacher in the family of Johann Taafe in the Moravian Brno, not far from Neumann's birthplace. Prechtl needed such a colleague! The men set up an extremely effective pair, in which Prechtl offered to their Viennese school high scientific and technical achievements, and his secretary Neumann took care of an exemplary managed institution and library. Their tandem a great success, as it happened a century later in Ljubljana during an exemplary collaboration between the scientist mathematicians the first rector Plemelj and the second rector of the University of Ljubljana, Rihard Zupančič. Prechtl and Neumann's associate, the professor of mechanical engineering at the Polytechnic, Johann Arzberger (* 1778; † 1835), provided the technologically knowledge needed in the school; first he was the director of mechanical engineering in Moravia, and then he helped Prechtl's introduction of gas lighting in Vienna before Edison penetrated with his vacuum electric light bulbs. Arzberger's best student and his assistant until his death was Ferdinand Jakob Redtenbacher. Among Neumann's most important colleagues at the Polytechnic in Vienna was Christian Doppler (* 1803; † 1853) between 1829 and 1835. Doppler excelled by his explanation of Doppler's effect.

Neumann lived in the center of Vienna at Ballgasse no. 987. He closely collaborated with the composer Franc Schubert (* 1797; † 1828), who vainly competed for the position of a teacher at the new musical school in Ljubljana within the framework of the Ljubljana Real school in autumn of 1816. Schubert wanted to go to Ljubljana soon after Neumann's resettlements to Vienna. Although Schubert was recommended by his and Beethoven's teacher Antonio Salieri (* 1750; † 1825), the people of Ljubljana preferred to choose a Celovec (Klagenfurt) music teacher of the Czech genus Franc Sokol (Sokoll, * 1779, Sadská; † 1822, Ljubljana). The people of Ljubljana did not see Schubert good enough as their new teacher, while their former professor Neumann wrote in the Viennese capital the songs for Schubert's music. Salieri's older brother and teacher Francesco was a Paduan pupil of violinist and mathematician Giuseppe Tartini. Unfortunately, together with the new Viennese professor Neumann, nobody could convince the people of Ljubljana for Schubert's advantage. It may also be the right case, since Ljubljana would soon become too narrow for Schubert, as it became to his friend Neumann a decade earlier.

15.10.5 Textbook about Physics

Neumann liked the book of physicist employed as a senior Bavarian financial councilor Julius Conrad Count Yelin (* 1771; † 1826) Lehrbuch der Experimental-Naturlehre und seinem chemischen Theile, nach dem neuen System bearbeitet (1796 Ausbach). Neumann also recommended writers of the textbooks which he preferred. Among them was the Rostock university botanist the early proponent of Lavoisier's anti-phlogiston chemistry dr. Heinrich Friedrich Link (1767 Hildesheim-1851 Berlin). Link's textbook *Grundriß der Physik für Vorlesungen* was published in Hamburg in 1798. Neumann also liked Michael Hube's (Jan Michał, 1737 Toruń (Thorn) in Northern Poland-1807 Potycz in east-central Poland) *Vollständiger und fasslicher Unterricht in der Naturlehre: in einer Reihe von Briefen*, published in several volumes in Leipzig in 1790-1791 and in 1801-182. Hube used to be Abraham Gotthelf Kästner's (1719-1800) student in Göttingen where he published his students' work *De sectionibus conicis* in Leipzig in 1755 with German translation: *Versuch einer analytischen Abhandlung von den Kegelschnitten mit einer Vorrede von A. G. Kästner* issued in Göttingen 1757. Neumann recommended the Protestant astronomer and designer of vacuum pump Johan Gottlieb Friederich Schrader's Grundreich der Experimental-Naturlehre in Seinen Chemischen Theile printed in Hamburg in 1804. Among Neumann's favorites was M. Hell's student the astronomer Catholic priest Longinus Anton Jungnitz's (1764 Męcince (Hermannsdorf)-1831 Wroclaw) Grundriss der Naturlehre zum Gebrauch fuer Vorlesungen published in Wroclaw in 1804. Neumann praised the freemasonic professor of medicine, physics and chemistry in Erlagen

Friedrich Hildebrandt's (1764 Hannover 1816 Erlangen) *Anfangsgründe der dynamischen Naturlehre* (1807, Erlangen). T. Gruber's collaborator Gren's textbook (1808, Halle) was still among Neumann's favorites together with the supporter of Rumford's theory of heat translation

Figure 15-62: Neumann's illustration of hydrostatic paradox, hydrostatic pressing of capillaries and vacuum phenomena at the end of his Latin textbook, published in Graz in 1808.

the first rector of Tartu university Georg Friedrich Parrot's *Grundriß der theoretischen Physic: zum Gebrauche für Vorlesungen* (1809 Riga-Leipzig). Naturally, Neumann liked the professor of chemistry who taught Justus von Liebig, the Protestant Karl Wilhelm Gottlob Kastner (1783-1857 Erlangen). Kastner published Grundriss der Experimentalphysik edited by Mohr and Zimmer

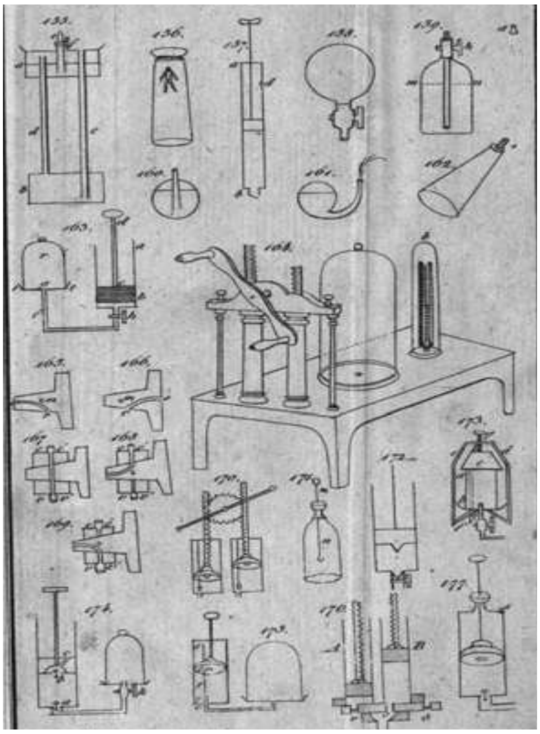

Figure 15-64: Table VIII of Figure 596 of the first part of Neumann's German textbook, which in Figures 173-177 illustrated experiments with vacuum pumps described on pages 375-378 of the first part

in Hiedelberg in 1809 and in 1810. Neumann also approved the experimental physics of Johann Tobias Mayer (1812). Neumann equally recommended the textbook of researcher of gases Kästner's student Georg Gottlieb Schmidt's (Luftschmidt, 1768-1837 Giessen), Handbuch der Nauturlehre published in Giessen in 1817. Another Schmidt's textbook about the spherical trigonometry was printed in Giessen in 1817.

Neumann recommended Dutch chemistry and physics in his introduction to the textbook, including the Dutch 'sGravesande and Musschenbroek's Institutions (1748) and Introductio ad philosophiam (1762); the choice was related to Musschenbroek's valves of vacuum receivers that he used in Ljubljana. Neumann enjoyed the French textbooks titled Traité, among others, like French Haüy (1806, German translation by Christian Samuel Weiss (1780 Leipzig–1856 Cheb in Bohemia) or Johann Georg

Ludolph Blumhof (1774 Hannover-1825 Giessen) in 1804, A. Libes or JB Biot (1816) who also published his Precis in Paris in 1817. Other Neumann's favourite textbooks were published by François Sulpice Beudant (1787 Paris–1850 Paris) (Essai, 1815, Paris), Tiberius Cavallo (The Elements, 1803, London), Thomas Young (Lectures, 1807, London), J. Playfair (Outlines, 1814, Edinburgh), Ranieri Gerbi (1763-1839 Pisa) (Elements 1818, Pisa) and Giuseppe Saverio Poli (Elements 1819, Venezia). Neumann examined Cavallo and Poli's books at the library of Žiga Zois, whom Neumann visited as a professor in Ljubljana. Neumann recommended dictionaries compiled by JST Gehler (1787-1795, Leipzig), JR Meyer (1806, Arau), Hutton (1815), Brison (1781, Paris) and Alexandre Brongniart (1770 Paris–1847 Paris) in collaboration with Cuvier (1804-1805, Strasbourg). Among the histories of physics, he emphasized JC Fischer (1801-1808, Göttingen), J. Gilbert (1811, Leipzig) and the journal Archives et découvertes et des inventions nouvelles, faites dans les science, les arts et les produits, tant en France que dans les pays étrangers (1808, Paris: Treuttel

Würtz) with many articles of Gay-Lussac, Biot, Fourier and Oersted.[1984]

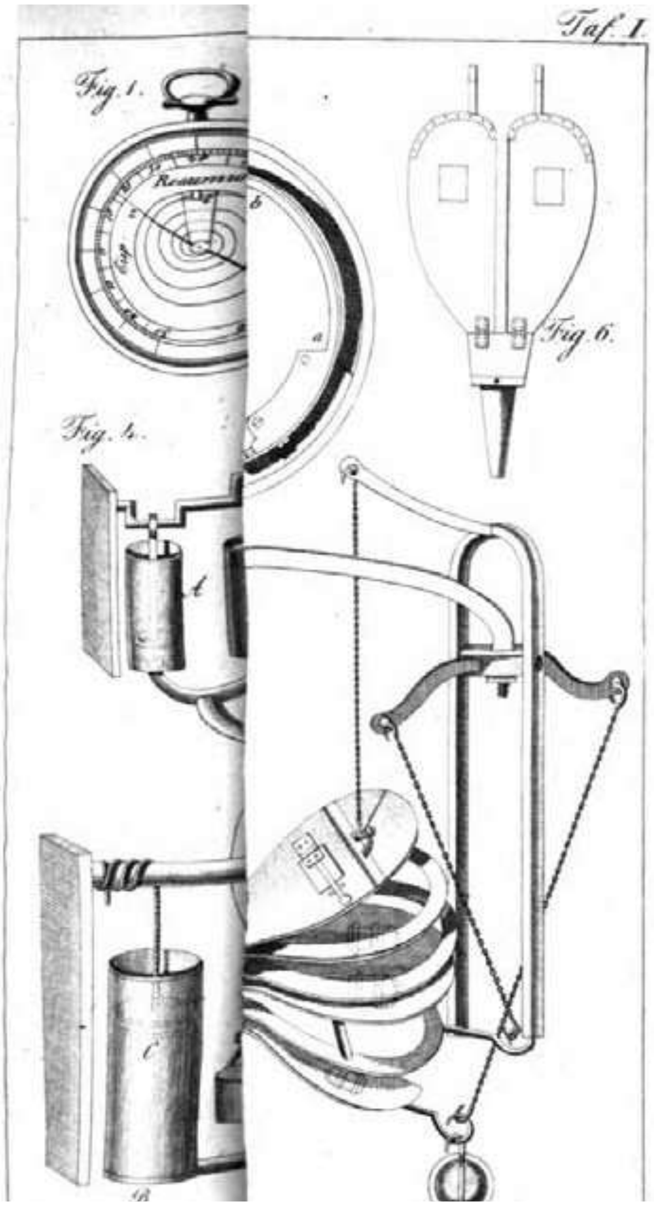

Figure 15-68: Pictures published in Neumann's discourse from 1819 on page 521 in Table I under numbers 1-36

Among Neumann's recommendationswas the professor of physics, chemistry and natural sciences at Heidelberg University, Georg Adolf Suckow (* 1751; † 1813), who published *Anfangsgrunde der Physik und Chemie* (1813, Augsburg); Neumann liked the liberal Anti-Semitic Hegel's antagonist Jakob Friedrich Fries' (1773-1843 Jena) *Entwurf des Systems der theoretischen Physik* (1813, Heidelberg), Hildebrandt's and J.T. Mayer's Erlangen student Carl Wilhelm Bockmann's (1773-1821 Karlsruhe) *Leitfaden zum Gebrauch bei Vorlesungen über die Naturlehre* (1813, Karlsruhe), Thaddäus Siber's (1774 Schrobenhausen in Bavaria-1854 Munich) Anfangsgründe der Physik und angewandten Mathematik (1815) and, basically, Neumann's own co-worker in Viennese Polytechnic the porcelain firm director Benjamin Scholz's (1786 Slezské Rudoltice (Rosswald) in Bohemian Silesia-1833) *Anfangsgründe der Physik als Vorbereitung zum Studium der Chemie.* After Scholz passed away, his fellow Bohemian Andreas Baumgartner took over porcelain firm directorship in 1835. The porcelain became one of the leading product of applied physicst after its secrets were revealed from the Chinese for Parisian suburb fabric of Sèvres. Neumann also recommended other technical expert writers such as the pioneering educator of pharmacists Johann Bartholomäus Trommsdorf's (1770 Erfurt-1837) *Chemisches Probierkabinet oder Nachricht von der Bereitung, den Eigenschaften und dem Gebrauche der Reagentien* (1817, Gotha), Georg Christoph Lichtenberg's (1808-1818, Vienna) editions of Lichtenberg's friend Erxleben's *Anfangsgründe der Naturlehre*, Friedrich Christian Kries' (*1768 Thorn; † 1849 Gotha) *Lehrbuch der Physik* (1816, Jena), the private tutor of brothers Humboldt Ernst Gottfried Fischer's (1754-1831) Lehrbuch der mechanischen Naturlehre (1819), the Heidelberg university professor of physics Georg Wilhelm Muncke's (Munck, Munke, 1772 Hilligsfeld-1847 Großkmehlen) *Anfangsgründe der Naturlehre* (1819, Heidelberg) and Wilhelm Gilbert. Among Habsburg Latin textbooks, Neumann again recommended Ambschell (1807), along with Ambshell's successor to the Viennese chair the Piarist Remigio Döttler (1812, Vienna, Trieste) and Neumann's own Graz textbook from 1808-1812.

15.10.6 Conclusion

Neumann's recommended reading were certainly in the mainstream, but he totally abandoned the Jesuitical relevant Catholic or even Habsburgian researchers. The physics in Ljubljana finally became a cosmopolite erudition where Neumann was able to recommend even the highly suspicious antiestablishment post-Kantian Jakob Friedrich Fries. Ljubljana's professors and vacuum technique researchers would find it difficult to name anyeone who has so many references on the web and in the literature as exactly Neumann. Of course, the lion's share of his fame comes from cooperation with even more famous Franz Schubert, but nothing's

[1984] J. P. Neumann, *Lehrbuch* 1820, 2: XIII–XIV.

wrong with that. Glory is glorious no matter who is its godparent! Certainly, Neumann deserves a kind of memorial plate in Ljubljana or at least a street with his name, as one of the oldest members of the DVTS Alojz Paulin constantly draws attention to the fact that Slovenians are eager to call their streets in all sorts of humanists, and very reluctantly by scientists and technicians, and especially not by vacuum researchers. Neumann is an excellent opportunity to avoid this disproportionate disparity: in the same person, he combined the successful poet of Schubert's compositions and physics, skilled in experiments within a vacuum. Neumann is therefore a rare example of a famous man, in whom both humanistic and technical scholars of Slovenia can agree to praise and commemorate his glory in their capital. Near his former Viennese Polytechnic, today the University of Technology, he has his memorial record under the tower of the belfry, not far from the church, while it is by no means necessary for the people of Ljubljana to lag far behind their former Viennese capital.

16 Vacuum for Entertainments - Balloons

16.1 Vacuum Balloons

Neumann's Viennese boss Prechtl used to be one of the best theoreticians of ballooning, especially by his comments of the flight of the Carniolan Kraškovič. One of their biggest hints was the puzzle of the best balloon filaments: would it be possible to live it empty? Objects float in the liquid due to buoyancy. The biggest lift is obtained by completely emptied balloon. However, the framework of a balloon must be firm enough to withstand the external pressure and prevent implosion. Is the Vacuum Balloon Possible?

16.1.1 Exploitations in the Sixteenth Century

A quarter of century after Torricelli, Fabri described an airship in Lyon. According to Aristotle, he assumed that the air had "lightness" in contrast to the gravity of the earth or water. He wanted to get as much air as possible under high pressure in the sphere, as he anticipated that he would then be striving upward.[1985] The idea was clearly wrong also in contrast to Torricellian air pressures and even with later Lana's vacuum ballooning. Fabri's airship would certainly make a bad flight, just like Einstein's planes a quarter of millennia later, mostly because the purely theoretical considerations might be sometimes relevant for experimentation, but they are hardly ever usable for direct technological applications. In 1726, Fabri's book was acquired in the Jesuit library in Ljubljana.

Lana did not use Guericke's or Boyle's vacuum pumps, although he knew them from Schott's books. He imagined four spheres of copper sheets in which the air would be much heavier than its skeleton made of copper. When the air was exhausted from balls, they would be fastened with a belt to a wooden boat. The ship should be as light as possible so that the crew can sail like ship on the water. Each of the four spheres would be connected to a long copper tube that could be closed by a tap: "First of all, I will assume that the air has weight like the steam. Air rises from the earth and the sea a few miles high and surrounds the Earth. The philosophers cannot deny this fact. We can prove it by pumping out air from a glass container if we cannot exhaust all the air. This reduces the weight of the container. I found the weight of the air itself at the following manner: I bought a large glass container, whose door could be closed or opened with a tap. I opened the container and warmed it up and removed the air from it. When I got most of the air out of the container, I quickly closed it so that the air would not come back. I weighed the container. Then I connected the container door to the water and opened the tap, so that the water filled most of the container. I pulled out the door from the water, drained water from the vessel, and measured the quantity and density of water. I found out that the amount of air that left the container is equal to the amount of water that filled the container. The water filled the part of the container left by the air. I again weighed the dish after I dried it well and removed the moisture. I found that the container, together with air, weighed 1 ounce[1986] more than after I washed out most of the air. The difference corresponds to the air with the volume of water that took its place. The water had a mass of 640 ounces. So, I found that the weight of air is 640 times less than the weight of the water."

He measured a 20% lower value of the ratio between the density of water and air than we acknowledge today. He used Euclid's finding of increasing the surface of a sphere with square of diameter and volume with a third exponent of diameter. He designed a hollow spheres of diameter close to 8 m with a thickness of the frame about 0.1 mm:

"In order to prepare a ball capable of lifting larger masses and transport people by air, we use 170 m^2 of copper[1987] weighing 140 kg…[1988] The ball will contain 326 kg[1989] of air. If the air is exhausted from the ball, three or at least two people with a

[1985] Fabri, 1669, 153.

[1986] 28.35 g.

[1987] 1,232 square feet, each 372 mm long.

[1988] 308 lbs. (pound) each 453.59 g. Such amount of copper with density 8500 kg/m^3 should be enough for 0.1 mm thick layer of ball with a diameter 3.68 m.

[1989] 718 lbs. 4 2/3 ounce. That mass should have a ball full of air with the diameter 3,68 m if air could be just 640 times lighter than water.

total weight of 186 kg[1990] will be able to raise. The larger the ball, the thicker and stronger the copper plates must be. The weight of the sphere is increasing, but with the weight of the air contained, its capacity is increasing. This way bigger balls can lift heavier loads. From here we can easily see how we can build a device in the form of a ship that will float through the air."

The ship could be propelled by the rudders and sails on masts. He pointed out the operation of a later propeller and claimed that, due to air pressure, the oars or blades would cause any vessel to move. Lana did not specify the air pressure required for the propulsion but envisaged all the conditions and difficulties in making the airship: "I cannot foresee other problems that could prevent such an invention, except the largest, since God will certainly never allow the operation of a device that would cause so much disturbance in the civil and military administration." He assumed that airships could ignite boats at sea and bombard houses and fortresses. No one would be safe from surprise. The assumption of a new mode of warfare came true, although Lana did not predict any successful defense. In 1686, Lana again described his aircraft in a solid book of a large format, but without images. The book was acquired by professor of mathematics and physics B. F. Erberg for higher studies in Ljubljana several years before Vega's birth. Vega certainly liked the fictional idea when he read about it in the school library. Lana accurately described Torricelli, Boyle's and other experiments with gases and vacuum. He presented the opinions of the important Jesuits Fabri, Lana's teacher Kircher and Schott. Like other Italian Jesuits, he criticized Galileo[1991] because he could not reconcile his research with Aristotle. The Jesuits of those days, like Aristotle, still claimed that the space is defined with the substance it contained, which made the absence of substance troublesome especially in the Latin descriptions. Therefore, when describing the airship, Lana avoided discussion of the vacuum, but acknowledged the existence of air pressure. The middle path was necessary, since the Jesuits, such as Lana and his friend, rector of the Roman Jesuit College D. Bartoli, had to obtain the consent to print their experimental research by the Jesuit censors favoring Aristotle. The mathematician in Pisa, Borelli, was one of the leading researchers of possible flights. Together with Leibniz they opposed Lana's assumptions. They argued that the vacuum ball would collapse into itself, as Guericke had already witnessed in 1640 during his pumping air from wooden and bronze barrels. Despite criticism, the Jesuits continued to admire Lana's airship for a long time. That shipbuilding, of course, intended primary for navigation on the water, was one of the prestigious Jesuit technologies. The production of ships and models for them has become the most important activity of Vega's Ljubljana professor Gruber a century after Lana's book.

The Dubrovnik citizen **Brne (Bernard) Zamagna** was the pupil of his compatriot Bošković at the Jesuit College in Rome. In 1768 he studied theology there. As he used to be one of the most important Croatian Latin poets, Zamagna's rhymes stuck primarily on scientific issues.

In 1768 Zamagna published 1473 Latin hexamers in two books about Lana's ship. Other scientific questions were also involved in the poem: the fear of empty, the nature of the force of gravity, the natural science of his own censor Dubrovnik native Benedict Stay, the talk of a multitude of worlds written by the later life-long secretary of the Parisian Academy Fontenelle in 1686, Copernicus and Columbus's discoveries, magnetic declinations, difficulties in measuring the meridian, Borelli's aerodynamics, Newton's and Bošković's research of the atmosphere around the Earth and the Moon. In the year 1769, Bošković's path to California was foreseen to observe the transit of Venus across the surface of the Sun. Zamagna's song was reprinted in Graz and Vienna in 1782 and 1784 with the preface and remarks of the former Jesuit, the Hungarian Paintner, Domin's friend and classmate in Leoben in 1772. He became a priest in Sopron, and he was later promoted to the title of bishop and counselor of the Viennese court for religious questions. In his foreword Paintner summarized the entire history of the airship. In the first half of the 4th century BC the Pythagorean arithmetician Plato's model of a philosopher-king Archytas (Αρχύτας, 428 Tarentum (now Taranto in Southern Italy)–347 BC Tarentum) accomplished the flight of suspended

[1990] 410 lbs. 4 2/3 ounce.

[1991] Domin, 1987, 175–177; Lana, 1684, 1: 3, 175, 177–178; Lana, 1686, 2: 176, 291–294; Lana, 1692, 3: 214, 215, 238, 239, 262, 297, 551.

wooden pigeons propelled by a hidden jet of compressed steam. In the 14th century, Jean Buridan's Parisian student the Augustinian bishop of Halberstadt Albert of Saxony compared the flight through the air near the fire with the buoyancy on the surface of the water with the air above it. Albert argued in his theory of impetus that the air near the fire resembles the surface of the water bordering the air. Later the Jesuit professors from Prague also discussed that interesting problem of Lana's airships.

Lana correctly calculated the buoyancy, but he did not consider the strength of the spheres. He estimated the cost of manufacturing an airship to only 100 golden coins, but due to vow of poverty, he could not even provide this relatively small sum.[1992] Thus, he was saved from his disappointment at eventual observing the external pressure, which would surely implode his balls. Lana likewise envisioned the use of balloons to the quarter of a millennia later Potočnik Noordung's planned development of rocket and space technology.

16.1.2 Vega and the First Balloons

The first balloon flight was indeed a jump at the beginning of the 18th century in 1709 by Portuguese-Brazilian ex-Jesuit Gusmão in Lisbon. The Portuguese Bartholomeo de Gusmão was the first to fly. He used the device filled with a warm air and reached to the height of the roof of the royal palace. His achievements were wrapped up in the dark, as the Inquisition threw him into prison; luckily, his faithful friends helped him escape to Spain. On 17. 3. 1709 he was rewarded by the Portuguese king. Later, Gusmão failed to meet all the expectations of the authorities For almost a century after his death, the ballooning ship was hosted by Brothers Montgolfier. They were the owners of the paper mill in Annonay, therefore they used soft and expandable frames instead of hard balls. On June 17, 1783, a balloon with diluted air passed over Paris. Among the crowd of curious people, the King Louis XVI, Benjamin Franklin and Barthélemy Faujas de Saint-Fond, naturalist at the Paris Museum, viewed the flight. Faujas immediately added the flight report to a book he published in Paris that same year. He estimated that Lana's ship would be better opportunity compared to Montgolfier's design (Figure 16-1).[1993]

The books related to Aerostatics went for honey. For Ljubljana's Lyceum library they acquired a dozen French, English and German works on aerostatics printed between 1783 and 1786, most of them Faujas' books. Many experts valued Montgolfier's balloon including Roy, Tillet, Brisson, Cadet, Lavoisier, Bossut, de Condorcet and Desmarest for the Parisian Academy. All of them suddenly wanted to fly through air, while the French Revolution was preparing its bloody dance on the ground.

Figure 16-1: Montgolfier's Balloon above Versailles

Jurij Vega soon heard of the success of Montgolfier brothers, since the former Benedictine Franz Übelacker in translated Faujas' work after the Paris Edition within the year. Of course, the Germans were not able to confess the any French superiority, so Übelacker described four hundred years old flight surveys in Germany. On 6. 6. 1784 Vega watched the first Viennese flight of a hot-air balloon. In the same year, he was promoted to the

[1992] Lana, 1670, paragraph VI; Domin, 1987, 177, 175.

[1993] Domin, 1987, 177–178; Faujas, 1784, 3 (introduction), 248–249.

lieutenant and issued another part of his mathematical lectures in Vienna. Also, the professors of physics Rozier and d'Arlandes who became Major in 1781, were also impressed with the balloons. On November 21, 1783, six minutes before the two o'clock in the afternoon, Rozier and d'Arlandes let a balloon with diluted air above La Muette in Paris. Subsequently, Rozier became the first victim of promising air traffic. During the overflow of the English Channel, his burner inflamed hydrogen in his small balloon of combined hydrogen and warmed air filaments. The Croat Ivan Baptist Horvat published the first description of a flight by aerostat balloon full of hydrogen in Buda in 1783[1994] in the later Charles's style. On the 1st of December 1783, the Sorbonne professor Jacques Alexandre César Charles and his brother Robert were flying with such a balloon for the first time on the order of the Parisian Academy. Charles chose the newly discovered hydrogen by mistake, as he thought that it was also used by Montgolfier. The decomposition of water for production of hydrogen and oxygen was discovered by Lavoisier in 1783 and published on April 1st-4th, 1783 with Meusnier and Laplace at the Parisian Academy. General Jean-Baptiste Meusnier was a correspondent member of the AR since 1776. Two days after Charles's flight, on December 3, 1783, the AR published Meusnier's hydrogen balloon flight theory. The following year, the British were impressed by the novelty.

On March 1, 1784, Franjo Josip Domin designed his hydrogen filled balloon in the courtyard of the house of Francisco Andrea de Stainer in Gyor, Hungary. He has tested similar devices for seven years. On 1. 3. 1784, Domin as the first in Hungary released a balloon full of hydrogen over the courtyard of the house of Francisco Andrea de Stainer in Györ (Raab). He also assembled air pumps, fused with charcoal. Following the example of Fontana and Ingenhousz, charcoal was used to improve the vacuum in the mercury barometer (Figure 16-2).[1995] The process was discovered in 1772 by Fontana, a professor of logic and physics in Pisa, and then in Florence, where he was also a physicist at the court of Tuscany of the Grand Duke Leopold I. Domin knew well Ingenhousz who was a doctor of the Viennese imperial family between 1768 and 1779.

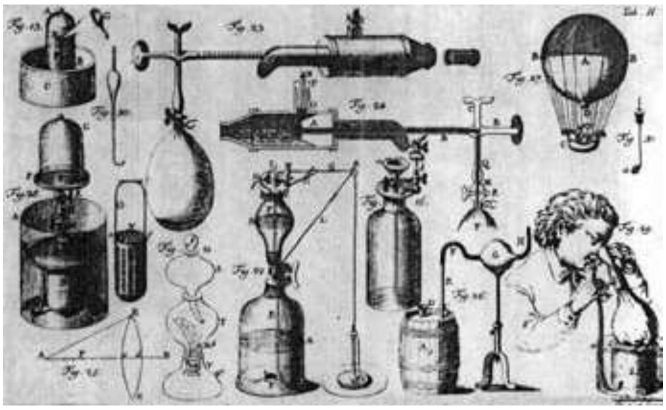

Figure 16-2: Domin's aerostat and vacuum pump (Figures 27 and 28)[1996]

[1996] Domin, 1987, at the end of a book.

Vega learned about the vacuum and balloon experiments during a study in Ljubljana and later described them in his books. In his time, the choice between a vacuum and a filled balloon was no longer questionable. As an experienced practical physicist, he rejected Lana's model, like Borelli and Leibniz before him. Vega said that "because of the pressure of the external atmosphere on the surface of hollowed empty balls, it will not be possible to thin enough the metal shells to enable resisting the weight of outside air." This caused the essence of the problem and Vega supported the charge of balloons with hydrogen[1998]

16.2 A Slovenian with a Vacuum Balloon and his Last Will (on the 250th Anniversary of the Birth of the Pioneer of Slovenian Flights Gregor Kraškovič of Bloke)

16.2.1 Introduction

Neumann and his superior Prechtl closely followed the development of vacuum techniques for balloon flights, among which the flying Carniolan hero Kraškovič glittered. Upon the balloonists' tragedy on August 23, 2012 on Barje by Ljubljana, it is worth mentioning the first Slovenian balloonist Gregor Kraškovič, who published a fundamental work in the history of aviation, both in Slovenia and abroad. Kraškovič's book was printed over two centuries ago in Vienna. During his early years he performed a total of 65 flights. He tried to revitalize a century and half old idea of Lana Terzi about the flight under four vacuum balloons.

16.2.2 Training of a Future Balloonist

Gregor Kraškovič was born at Bloke in Inner Carniola. He studied the first grade of poetics in lower studies (gymnasium) in Ljubljana in 1788 with the Emperor's scholarship (Caesar) among the relatively younger schoolmates born around 1773. Kraškovič won the first prize (premier, Primae classis) immediately after two award winners Martin Rachnet from Dob and Nicolas Iggel accompanied by Lucas Burger from Kott (Winklern) above the river Čabranka and Matheus Barthol from the parish Loški Potok (Lasserbach, Laserbach). Apart from Iggel, who afforded his studies with the help of the Umek Foundation, all three of them received the emperor's scholarship, just like Kraškovič. Burger and Barthol were even Kraškovič's relatively close neighbors. In front of Kraškovič, the first receiver of premium Sigmundus Gandin de Lilienstein (Andrej, * Hrib (Obergörtschach) along the Lake Črnava in Preddvor, † 1791) was listed. He studied with the help of the Polidor de Montagnana's (Montegnana, * Italy; † 1604, Novo mesto) Foundation. The Foundation was established after the Archduke Ferdinand hinted on Montagnana on May 12, 1599, to hand over his Rogaška benefits to poor students.[1999] Their classmates were the count of Ljubljana Vincent Lichtenberg, Mathias Miller from Škofja Loka, Liburnia (Rijeka) native Franc Persich, Cerknica native Joan Petrisch, Georgius Pfeiffer from the parish of St. Martin, Ljubljana natives Michael Pinter and Andreas Potrata, Vipava native Martinus Stibiel, Škofja Loka native Antonius Uhl and Radovljica native Mathaeus Wenger. The other receivers of premium were Franc Janeshitsch of Ljubljana and Franc Okorn, along with Vipava native Johannes Slocker.

Kraškovič was not born at the vicinity of the Loški potok parish. Kraškovič was also not born in Vrhnika, east of Lož or Podpreska, south of the Loški brook, the areas inhabited by the Gottscheers (Kočevarji).[2000] Most of his documents on his schooling in Ljubljana in the class of physicist Schaller and mathematician Anton Gruber and in Vienna with the physiologist Georg Prochaska show his native parish Bloke in Inner Carniola (Notranjska).

16.2.3 Kraškovič on the History of Aviation

In the white world, Gregor Kraškovič slightly arranged his own surname Krashoviz, perhaps for similar initiatives as his elder compatriot Jurij Vega, who still used his original surname Veha at his schools in Ljubljana. Kraškovič was also Krashoviz in Ljubljana's schools, and the unusual "k" was later added to his surname, but not in connection with the Croatian town of Krašković, 100 km north of Slavonski Brod. Immediately after graduation, Kraškovič began collecting balloon data in 1789; perhaps he was helped by a youthful experience from the traditional domestic Nordic skiing in his native Bloke. In 1796, he was promoted to the rank of Doctor of Medicine at the University of Vienna;[2001] perhaps he helped himself with the scholarship of his distant relative, Janez Kraschkowitsch (Johann Kraschkowitsch), in the annual amount of 67 florins 6 kreuzers, which was intended for high school graduates' Viennese studies of Law and Medicine, so that the Carniolans were very interested in using it.[2002]

After the promotion, Gregor Kraškovič practiced in Vienna in 1797 as an external member of the medical faculty; he abandoned the practice the following year when the doctor of the Faculty of Medicine was also Joseph Anton Haymon, while among the philosophers were Joseph Liesganig, Anton Ambschell and Carniolan Franz Karpe.[2003] It seems that Kraškovič left Vienna and then served for some time in Zadar, where after his departure, on 18 August 1807, the Dalmatian guys released from the Zadar Plains a unmanned balloon in honor of Napoleon's birthday and peace treaty signed with the Russians.[2004] After the death of the Varaždin county (provincial) physicist from Luxembourg, Joannis Baptist Lalangue (* 1743; † 20. 5. 1799, Varaždin), Kraškovič became his successor. In the 1800's, he was engaged in obstetrics-maternity and the education of pregnant women in Varaždin. Kraškovič was a provincial physicist in Varaždin between 1799 and 1804,[2005] where he also proved himself to be the pioneer of medicine of workmen. In Varaždin, he carried a high cylinder hat in three levels or maybe a tricorne; over his white trousers he liked to wear a blue or green fringe. On February 1, 1805, as a practicing physician from Vienna and a district physicist, he reported about his 1500 vaccinations against smallpox virus in Varaždin to John Walker (* 1759; † 1830) from the London Royal Jennerian Society of Edward Jenner (* 1749; † 1823). Kraškovič vaccinated more than 110 children. Kraškovič got his Viennese vaccine from Dr. Jean De Carro (* 1770, Geneva; † 1857, Karlovy Vary (Carlsbad)); he used it as the first in the Varaždin environment. Most of the vaccinated were from poorer classes. Kraškovič also promoted vaccination in the neighboring lands in Hungary and Styria. Nearly for two years he fought in the Varaždin environment against infectious diseases of animals with such knowledge, success and happiness that the Hungarian authorities rewarded him with praise; he was also known as a botanist.[2006]

In the year 1808, Kraškovič and Ivan Nepomuk Menner (Maenner, Manner, Männer, * Western Austria) made the pioneering experiments with balloons. They performed their show on the possession of the emperor's royal chamberlain, the descendant of the Counts of Varaždin and the Dalmatian-Croat Slavonic ban–Sigismund Erdödy in Vepp (Vép), 8 km east of Szombathely. They used a round gas filled balloon. On its flight to the north, the balloon reached a height of 200-250 toise (fathoms) (klafter, fathom, 400-500 m). Then the balloon sailed south-east towards the then Turkish lands, as Kraškovič reported on seventy-eight pages of his historical-technical booklet on

ballooning in 1810.[2007] Like Kraškovič, Menner also had a Viennese medical practice, while he worked for a general hospital for free two years long. During the war against the French, he served the army with useful hospitalizations. Together with Kraškovič, Menner was one of the first to introduce Jenner's injection of a sample taken from cow suffering from cowpox.[2008] Menner served as a professor of mathematics at the Zagreb Academy between 1823 and 1841, where he was criticized as a German nationalist. In Zagreb, he printed at least ten collections of exam theses of his students in collaboration with the professor of physics, mechanic and economy Antun von Šufflay (Šuflaj, 1775 Samobor-1849) who was promoted with his Ph.D. of philosophy in Zagreb in 1803. Among their noble students was Emerik Ožegović von Barlabaševački (Emericus Osegovich, Imre, Mirko), promoted in 1828. In 1835 Menner promoted his student of mathematics of Spanish heritage Antun von Rubido de Zagorje (Antal Zuchý, * 1817 Klanjec or Madrid-1863) who married the first professional Croatian opera soprano singer the countess Sidonija Erdődy Rubido (1819 Zagreb-1888 Gornja Rijeka by Kalnik) in 1843. Antun Rubido was counsel vicegerent and a major under his general the Ban Josip Jelačić. His wife Sidonia as important member of the Illyrian movement first publicly sang the Croatian anthem in their castle in Zagorje in 1858, which was not in accordance with the supposed Menner's German nationalism.

Menner and Kraškovič learned their ballooning from other pioneers. In his balloon flights, Kraškovič proved himself as an exemplary student of the French Jean Pierre François Blanchard, who first flew over Viennese Prater on July 6, 1791. Blanchard had dreamed of flying in childhood years and the duke had already entrusted him with the construction of a water turbine near his castle at Vernon when Blanchard was a nineteen-year-old teenager. In 1777, Blanchard impressed Benjamin Franklin with his mechanical vehicle, which he drove from Paris to Versailles in an hour and a quarter. After the invention of the balloons, Blanchard of course began to fly under them, also with the royal support. He flew over Philadelphia and, after returning to Europe, he compiled three machines; unfortunately, his air fleet was hit by a thunder which killed his only eighteen-year-old son.[2009]

Kraškovič curiously described Franklin's achievements;[2010] however, he also emphasized Fourcroy's military use of balloons for the observation and transmission of telegraphic messages between French generals Etienne (Jean-Étienne Vachier Championnet), François-Séverin Desgraviers-Marceau (* 1769; † 21. 9. 1796, Altenkirchen) and Joseph Sebastien Meyer (* 1763; † 1834).[2011] At the battlefields near Rhine, the French captain and first officer of aerostatics corps Jean-Marie-Joseph Coutelle (* 1748; † 1835) already used the ropes of the newly invented balloons of his friend Charles at the battle of Fleurs on 26 June 1794. The units of the Habsburg officer Jurij Vega attempted to prevent observational activity of the French balloons. On June 6, 1784, Jan Ingenhousz (* 1730; † 1799) released the first hot-air balloon without crew,[2012] which was certainly observed by Vega, while Kraškovič was still a gymnasium student in Ljubljana. Ingenhousz was close to Kraškovič and Vega as a pioneer of the vaccination against smallpox in the Habsburg monarchy after 1768 (of course, not by Jenner's procedure), by the installation of lightning rods in cooperation with Vega's superior Freemason Major Leopold Baron Unterberger (* 1734; † 1818) and by Ingenhousz's exploration of photosynthesis and gases. Vega, on the other hand, rejected the Lana's model to be distinguished from Lana's fan Kraškovič. Like Leibniz, Vega thought that "because of the pressure of an external atmosphere on the surface of hollow emptied balls, it will not be possible for metal shells to be thinned in such a way that they would be lighter than the weight of the air that the balls contained prior to its voiding." That's why Vega preferred the hydrogen filaments in balloon.[2013] In the case of buoyancy, Vega examined the motion of Montgolfier's warmed air

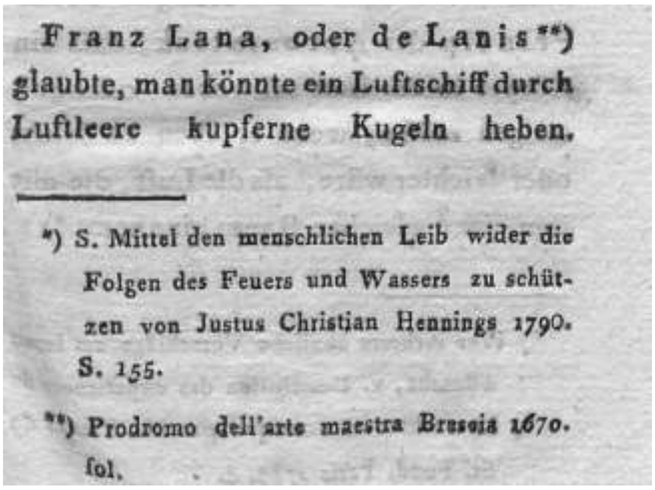
balloon,[2014] which was very popular for already ten years.

The French ideas were obviously very close to Kraškovič, since he began his book with a quote from Rousseau, which he had already used as an enthusiast dedicated lover of the nature; of course, he also quoted the Parisian playwright Louis-Sébastien Mercier (* 1740; † 1814).[2015] Among his practical examples he listed the experts such as Nicolas Louis Vauquelin (* 1763: † 1829), Klaproth, Berthelot, Fourcroy, Lavoisier, Volta, JB de Jacquin (Joseph Baron Jacquin (* 1766; † 1839)) , the translator of Lavoisier's work in Berlin in 1792 chemist and pharmacist Sigismund Friedrich Hermstadt (Hermbstädt, * 1760 Erfurt; † 1833 Berlin) and Gilbert.[2016] Gilbert was probably the famous little older Kraškovič's peer Ludwig Wilhelm Gilbert (1769-1824) who edited the main professional journal Annalen der Physik in Leipzig. He was probably not Wilhelm Gilbert, the legendary physician of the English queen.



Franz Lana, oder de Lanis **) glaubte, man könnte ein Luftschiff durch Luftleere kupferne Kugeln heben.

Figure 16-5: Kraškovič's notes on the hundred-forty years old ideas of the vacuum balloon of Franz de Lane Terzi from Brescia published in Lana’s book Prodromo[2017]

As a genuine lover of good meals of interior gourmet, Kraškovič was especially impressed by the trans-ocean voyages of importing potatoes from America, and he wanted to win the air space flights with balloons for more Transatlantic journeys.[2018] Of course, he started his presentation with Dedalus and Icarus, although he may not have been aware of the later disputes between the aircraft heavier and lighter than air. Then he turned to the more modern Johann Müller Regiomontanus (* 1436; † 1476). In 1467 Regiomontanus presented the eagle made from the woods and artfully made fly made from iron which flew the perceptible distance. His first audience were the

Kraškovič’s special attention was paid to **Franz de Lanis** (Jesuit Lana Terzi), who designed a vacuum balloon made of copper in 1670; his successful flight should, according to Kraškovič, be correlated with the principles of physics,[2019] as seen by Leibniz and the practical Otto Guericke. Francesco de Lana Tertio (Terzi) was the third child of the Brescia family; so, he signed himself as "Terzi[2020] In 1647 he entered the Jesuits’ order. He studied under supervision of the professors Casati and Kircher at the Roman College, where he particularly observed Kircher's experiments. He studied at the Roman College in Casati’s class and watched experiments at the Kircher Museum. At the Roman College, Athanasius Kircher raised many influential pupils, including Jesuit Francesco Lana Terzi of Brescia. Between 1656 and 1658, he taught philosophy in Terni north of Rome, in Rome, then in Venice. From 1675 Lana taught mathematics in Ferrara. A year before his death, he returned to the Academy Filesotici in his native Brescia. The publications of Filesotici were summed up even in the Leibniz’s Acta eruditorum.[2021] Lana was a correspondent fellow of the Royal Society of London. According to Fabri, his religious confrere, the Jesuit Lana, published in Venice the first useful plan for a flight of vacuum balloons with human crew (Figure 16-5. Later, Johann Christoph Sturm (Sturmius, * 1635 Hilpoltstein (Mittelfranken); † 1703 Altdorf) was thinking anew about Lana's airship (Figure 16-6). The bookshop Mayr offered first part of Sturm's two-year-old book to the people of Ljubljana in 1678. Sturm’s critique of Leibniz published in 1697 purchased by Erberg for the Ljubljana Jesuits in 1754 is still preserved in modern NUK.

local States General and the next the courtiers of the Emperor Friderik III in Nuremberg.[2022] In 1577, the Emperor Rudolf II ordered the dropping of a mechanical plane from the top of the Tower of Viennese St. Stephen Church.[2023]

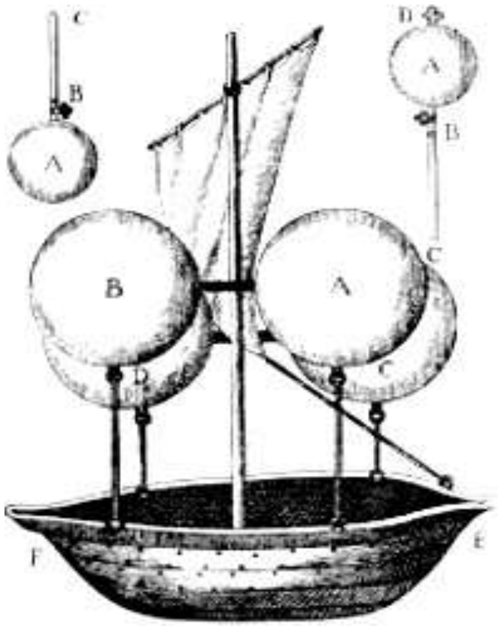

Figure 16-6: Lana's ship

In 1670, Lana became famous for production of round aircraft from copper sheets from which the air was exhausted; the idea obviously impressed the regional governor of Carniolan Volf Engelbert Auersperg at the time of his acquisition of the Lana's book. It is less likely that Volf on the roof of his Ljubljana palace tested the vacuum balloons, which still nobody designed until now. Lana's book was also read by the Ljubljana Franciscans. Leibniz has criticized Lana's idea; he thought that the vacuum ball would collapse to itself, as in his time Guericke's barrel collapsed during Guericke's similar experiments. Leibniz's concerns were reasonable, of course. Despite Leibniz's doubts, Leibniz's correspondent Philipp Lohmeier (* 1648 Magdeburg; † 1680 Lüneburg) published about the vacuum boat with balloons at the Universities of Wittenberg and Rinteln in 1676 and again after J.V. Auersperg's death in 1679.[2024] Lohmeier began as a teacher, from 1674 to 1679 he was full professor of physics at the University of Rinteln in Lower Saxony southwest of Hannover, then professor of rhetoric at the Gymnasium Johanneum in Lüneburg and inspector of the local Knights Academy. In 1676 in Wittenberg he published his Rinteln dissertation *De artificio navigandi per aërem* (About the art to navigate through air) which caused quite a stir, so that Wilhelm Ernst Tentzel (*1659 Greußen an der Helbe; † 1707 Dresden) discussed it in his monthly interviews (*Monatliche Unterredungen*) and thus made the event known beyond the local Faculty of Arts. Lohmeier took up the idea of the Jesuit Franziscus Lana Terzi from Brescia, who had presented the draft of an airship with building instructions in his *Prodromo* in 1670. Lana's basic idea was the plausible consideration that a body would have to rise into the air if it was lighter than the volume of air it was displacing. Lohmeier was enthusiastic about the idea of a buoyancy created by vacuum and gave lectures on the subject, as in 1674 at the University of Wittenberg. His own treatise on the possibility and technology of air navigation extended by some innovations became the subject of the examination of his pupil Franciscus David Frescheur (Prescheur, * Cassel) at the University of Rinteln in March 1676. In addition to that dissertation, Lohmeier published many pedagogical exam essays against judicial astrology (1674), starry heavens, earth, levitation, and gravity. He was praised by the leading minds of his time including his correspondence with Gottfried Wilhelm Leibniz. The subsequent also posthumous reprints and German translations of the Lohmeier's dissertation (1679, 1708 and 1784) prove the lasting interest and reputation of the deceased Lohmeier. Although the Lutheran theologist Johann Georg Walch (* 1693 Meiningen; † 1775 Jena) had plagiarized Lohmeier in 1726, Georg Christoph Lichtenberg a century after Lohmeier's publication expressed the wish that Lohmeier's dissertation should be made better known, which in 1784 led to the printing of a German translation (in Tübingen) and a bilingual, Latin-German edition of Lohmeier's book in Arolsen. At the end of the 18th century critical assessments of Lohmeier's accomplishments were made, as well as the questionable originality of some of his writings in relation to Lana and the *Collegium Experimentale Curiosum* of Sturm published in Nuremberg three years before Lohmeier's edition in 1676. In fact, Philipp Lohmeier copied verbatim his own treatise on the possibility of air navigation from the Jesuit Francesco Lana Terzi's (1631-1687) invention. Lohmeier fought for Lana's flight project. The admiration for Lana's idea even led him to lecture

about him at the University of Wittenberg in 1674 without naming Lana. He wrote a dissertation *'De artificio navigandi per aerem'*, which almost literally coincides with the sixth chapter of Lana's 'Prodromo' and adds only a few broadening suggestions without notifying Lana. Lohmeier described the works of Torricelli, Boyle and Guericke who used to be a mayor in Magdeburg when Lohmeier's father was a rector of Grammar school there. Lohmeier and his student may have ignored the Jesuit Lana's priority as the Protestants who disliked their theological antagonists the Jesuits, which might be fair supposition in Terpin's time but not any more in Lohmeier and Valvasor's era several decades after the Thirty Years War ended. In any case, Lohmeier's silence about Lana forced many (Germans) in false belief that Lohmeier invented Lana's ship. In the end of his narration, Lohmeier compared aerial navigation with the inventions of sable, guns and powder.

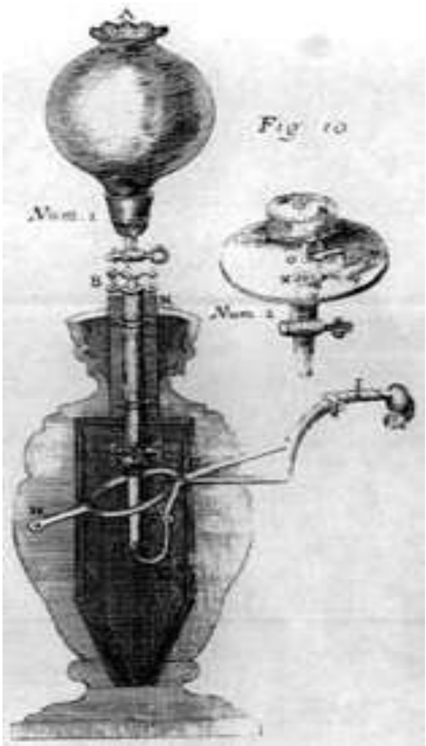

Figure 16-7: Sturm's air pump described in 1685

Lana's work was commented and pictured six years after Lana's publication by Johann Christoph Sturm (* 1635; † 1703), docent at the University of Jena, preacher and professor of mathematics in Altdorf from 1669 and later the rector; he was the father of the mathematician Leonhard Christopher Sturm.[2025] Two years after Mayr offered Sturm's book in Ljubljana, but Wolf Auersperg did not have it, even though it was bought by Auersperg's former informal student-client Valvasor.

Johann Christoph Sturm was a senior lecturer at the University of Jena, the preacher, and then professor of mathematics at the Altdorf University near Nuremberg. He was one of the most popular writers of textbooks in mathematics and physics of his time. In Ljubljana, Mayr listed four Sturm books right after Mayr's offer of Schott's works. Sturm's Physics selection was acquired by the Jesuit College in Ljubljana in 1754. He referred mainly to Fabri's vacuum issues but did not forget to describe Guericke's experiments.[2026]

Lana Terzi described four spheres of very thin copper plates: the air in them had to be much harder than a thin copper frame. The pumps would suck out the air from the spheres and Lana could fix them with the straps on a wooden aircraft shaped like a ship. The ship should be as light as possible, equipped with paddles, masts and sails. Lana's crew could supposedly navigate the air, much like water. Lana estimated that he needed 100 gold coins to make the device; but he could not provide even this relatively small sum. After the schooling in Brno, the composer Dubrovnik Jesuit Brne Zamagna wrote a poem about the lonely boat entitled the Navia Aeria. In 1784, he displayed his visions in Vienna.

The bettered Lana's idea was used by Brother Montgolfier a hundred years later; their balloons were rather loaded and they did not leave them completely empty. Lana was advocating solid discharged spheres, while Etienne (* 1745; † 1799) and his brother Joseph de Montgolfier (* 1740; † 1810) preferred soft and stretching balloons out of their paper mill. Their balloons were full of light steam. Out of congenital caution the Brothers Montgolfier loaded their homemade balloons with light gases and did not come completely empty. Before all their competitors, the brothers Montgolfier distinguished themselves as the owners of the paper mill in Annonay on June 5, 1783. The King Louis XVI, Benjamin Franklin and

[2026] Mayr, 1678, 91, 119

Barthélemi Faujas de Saint Fond attended the Montgolfier flight in Paris. Faujas added that report to his already prepared book, which was printed in Paris in 1783 and was purchased by Žiga Zois for his library in Ljubljana; the following year it was translated by the former Benedictine monk Franz Übelacker in Vienna, where Vega observed his first ascents with balloons.

The second flight under balloon filled by diluted warmed air was carried out by professor of physics Abbé Jean François Pilatre de Rozier (* 1756; † 1785) and his companion the military commander, major since 1781, François Laurent Marquis d'Arlandes (* 1742; † 1809) at La Muette at Paris on 21 November 1783 at 13:54.

To select suitable filaments of balloons, the brave aeronauts needed reliable data. The exact Felice Fontana's measurement of the density of the various gases became their fundamental guide.[2027]

Avguštin Hallerstein and his colleagues had three copies of the description of the Jesuit vacuum balloon of Lana Terzi[2028] in their Beijing libraries, and they also read about Montgolfier's balloon. The Jesuit Hallerstein scanned even the provincial letters of the leading researcher of the vacuum Pascal,[2029] although Pascal was a bit bitter to the Jesuits, and he sharply argued against the Jesuit Éttienne Noël.[2030]

Unfortunately, Lana's ship is still waiting for a successful flight. The third part of Lana's book Natural Science Teacher was a part of the library of the Carniolan Governor general Wolf Engelbert Auersperg, and Jesuits of Ljubljana acquired that book sixty years after the print. Lana accurately described Torricellian,[2031] Boyle's[2032] and other experiments with gases and vacuum. He presented the opinions of his important Jesuit co-brothers: Honorate Faber (Fabri),[2033] Kircher[2034] and Schott.[2035] He criticized Galileo in agreement with Giovanni Francesco Vanni (1638 1709 Rome) from Lucca, the Jesuit mathematician Tommaso Ceva's Milanese brother Giovanni Ceva (1647 Milan–1734 Mantua), and other Italian Jesuits.[2036]

Both Valvasor and Volf Engelbert Auersperg purchased a Lana's work for their libraries. Six years after the edition, Lana's work was commented by Johann Christoph Sturm (* 1635; † 1703), docent at the University of Jena, preacher and professor of mathematics in Altdorf from 1669 and later rector there.[2037] Two years after the release, Mayr offered Sturm's book in Ljubljana. Volf Auersperg did not have Sturm's work, even though Valvasor bought it. Valvasor also had Sturm's edition of Kepler's astronomy.

In Avignon, the Dominican Joseph Galien (Gallien, 1699/1700, Saint-Paulien, France-1762/1782) thought about areas above the atmosphere, which should also be full and usable for flying; he found the principles of aerostatics based on buoyancy. Lana's ideas were handled by the Dominican meteorologist-electrician Gallien in Avignon. He published the book L'Art de naviguer dans les airs, amusement physique et géométrique as anonymous in 1755 and with his full name praised in 1757. In 1766, Henry Cavendish discovered extraordinary lightness of combustible air now called hydrogen after Black has already experimenting with it.[2038] An Italian who moved to

[2027] Priestley, 1966, 181.

[2028] Lana's books had ex libris of French Jesuits in Beijing: "*P. P. Gallor p. J. Pekin, Collegij Societatis Jesv Pekini, Veyo da Residenca de Cinanfu*" (Lana Terzi, *Magisterium*; Verhaeren, 1996 *Catalogue,* p. 572–573) and with Hallerstein's bookplate "*Da Vice Provinciae da China da Compania de Jesus, Collegij Societatis Jesv Pekini, Vice Provinciae Sinesis*" (Francesco Lana Terzi, Prodromo, Brescia, 1670; Verhaeren, 1996 *Catalogue,* p. 971). The French Pekingese Jesuits, with their bookplate P.P. Gallor p. J. Pekin also decorated reports on vacuum research in the mercury barometer of Torricelli's heirs at the Academy of Florence, edited by count Lorenzo Magalotti (* 1637; † 1712) under the title *Saggi di naturali esperienze* (Verhaeren, 1996 Catalogue, p. 921 (no. 3136)). The same Bookplate had Schott's books: *Magia universalis, Mechanica hydraulica* and *Physica Curiosa* (Verhaeren, 1996 *Catalogue,* pp. 804–805 (nos. 2717–2719)).

London, Tiberius Cavallo and Lichtenberg happily carried out similar experiments with hydrogen; Žiga Zois also kept Cavallo's book on balloons. De La Fond's experimental physics strongly influenced the Slovenian balloon travelers, but above all Carniolan erudite admired the Naples native Cavallo. In 1771 Cavallo went to England, where in 1779 he became a fellow of the Royal Society of London. He was also a member of the Royal Academy in Naples. He published a book on electricity, which went through several reprints.[2039] In 1800, he built a refrigerator. Cavallo, like Priestley, defended the theory of phlogiston.

Figure 16-8: An arrangement of the Viennese professor of physics Anton Vanossi's (Antal Vanossy, 1683 Raab (Győr)-1757 Rome) with illustration of Lana's or Kircher's fracture of a rod magnet into halves. The Jesuit of Italian origins Vanossi also added the swimming of a fish designed for the movement of a vacuum balloon. Vanossi's book is kept at the Ljubljana Franciscans' library (Vanossi, Lana, Placita physica de Sympathia et Antipathia deprompta ex P. Franc. de Lana S. J., Vienna: Schwendimann, 12°, 1724, pictures at the end of the book refer to pages 226 and 265)

T. Gruber and chemistry professor at the medical faculty of the University of Halle, Gren,[2040] have criticized Darwin. Darwin's ideas were accepted by the Scottman Hutton,[2041] whom Darwin introduced in 1774 to the Lunar Society in Birmingham. Darwin was also advocated by Cavallo,[2042] who became famous for testing paper balloons in 1782.[2043] Cavallo was a member of the Royal Academy in Naples, and in 1803 he settled in London. Several Cavallo's works were kept in Zois's library in Ljubljana where Zois's tutor G. Gruber and his brother T. Gruber might have used them.

Of course, the ballooning experiments succeeded with Montgolfier and then with the Parisian physicist Jacques Alexandre César Charles (* 1746; † 1823) accompanied by his brother Robert. With their balloon thinly coated by linseed oil (wood finish), the brothers Charles made their taffeta balloon more flexible. They filled their balloon with hydrogen, obtained from iron or sulfuric acid. On 27 August 1783, they flew three-quarters of an hour from Paris under a 12-foot balloon, which rose within two minutes to the height of a kilometer. Of course, the then airplanes were split into two groups, in Montgolfier's filled by heated dilute air, and in Charles's filled with the flammable gas, hydrogen.[2044] The head of the museum, Pilatre de Rozier, happily watched the flight of the young Montgolfier while the king himself also attended; then Pilatre de Rozier flew together with Marquis d'Arlandes.[2045] They soon created a myth. A lot of brave people from lower and higher classes began to fly. The meteorological discoveries of aeronauts ~~s~~ under their balloons were accomplished one after another. Thus, J. Charles's Paris student, the Belgian optician Robertson (Étienne-Gaspard Robert, 1763, Liège-1837) found that the temperature of the higher air layers in the summer was not the same as in winter.[2046] In 1803 he looked at the atmosphere above Hamburg at a height of 360 "toise" (klafter, fathom, about 700 m). With his traveling companion August Lhoest, they found that the impact on Bertholet's powder did not cause an explosive break at all at these temperatures of 2

[2039] Cavallo, *A complete treatise on electricity in theory and practise with original experiments*, London 1777 (2: 1782 (in Zois' Library), 4: 1795). In the Lyceum Library in Ljubljana, they also acquired another Cavallo's book: The History and Practice of Aerostation, London, 1785. The book was catalogued in Zois' Library (NUK-8478). It was enumerated among the books which dealt with balloon flight that were extremely popular in that time.

degrees Celsius, high altitude, and with 26 inches of mercury barometer of diminished air pressure. The electrometer did not show any traces of electricity, since the clouds at this diluted air were extremely thin, and the solar rays did not show lively colors after their refractions through the prism.[2047]

In 1804, Gay-Lussac made experiments with a compass under the balloon; together with Arago, he measured changes in air pressure in a balloon above the rebelled Napoleonic Spain. At the height of 4 km, the magnetic needle did not fluctuate, and the weight of the balloon was balanced there by its lifting buoyancy; their pulse went below 30 beats per minute. The chemical analysis of the air captured at heights in a glass balloon, of course, showed that oxygen and nitrogen retained the ratio they have in the lower parts of the atmosphere.[2048] Gay-Lussac's name was used for the naming of an experiment where they passed gas from a full to an empty balloon. This experiment was often expressed by R. Mayer and others in the implementation of the law of conservation of energy twenty years later. That's why we can have Gay-Lussac's experiments as the precursors of "mechanical heat theory", which was already being created by his younger compatriot Sadi Carnot (* 1796; † 1832).

Herman Boerhaave reported burning alcohol in closed containers.[2049] Such an examination of physical phenomena Kraškovič described as the endless search directed against the imaginary year 2440, with which Kraškovič had already encroached on modern science fiction.[2050] The flights with balloons provided for the natural science a direct testimony of the composition of the atmosphere above the clouds, the distribution of sound there, the diminutions of the gravity, the refractions of light and all about the electricity in the summits of the atmosphere.[2051] Kraškovič's unnamed friend, who had already merits in aviation since his youth, thought that the balloon's flight can be directed, and the pilot could even influence the winds, including storms. There was a winning prize questions that encouraged aviation inventions parallel to the research of the poles and the interior of Africa; Paccassi also mentioned that competitive award. Kraškovič's unnamed friend was probably his frequent copilot Menner (Männer). Last but not completely least, in those times in Vienna they protected an imaginative patent with live eagles propelling a balloon, while the German inventor and musician Franz Leppich (* 1776; † 1818) in vain proposed to Napoleon his hot-air and hydrogen balloons. Hardly any more successes than those achieved by Leppich, Fjodor Vasiljevich Rastopchin (* 1763; † 1826) had in his military tasks in Moscow.

Kraškovič correctly realized that the knowledge of high atmospheric variable winds would enable us to anticipate the storms that threaten the ships at sea.[2052] Already d'Alembert studied the influence of the Moon and the Sun on the tides of the atmosphere as the cause of the winds, and accurate calculus were added by Edmund Halley.[2053]

16.2.4 Kraškovič's Balloons and Parachutes (Paragliders)

On March 4, 1810, Kraškovič and Menner launched their balloon made of a taffeta with a diameter of sixteen feet at the grandeur entrance of the Napoleonic minister of war Louis-Alexandre Berthier later marshal 1st Prince of Wagram Sovereign Prince of Neuchâtel (Neuschatel, 1753-1815). Their provisional "airport" was envisioned at the University of Vienna under the auspices of the court astronomer, the former Jesuit Franz von Paul Triesnecker (Drissenecker, * 1745; † 1817), the successor to Maximilian Hell. They reached a height of 150 klafter (fathoms), that is, close to 300 m, and then they landed a plane with a fixed parachute in Viennese Leopoldstadt without any damage.[2054] The Count Francesco Zambeccari (* 1752, Bologna; † 1812, Bologna) impressed Kraškovič with his balloon flight in a company with Pasquale Andreoli (* 1777; † 1837) over Bologna in 1783 and then above Vienna; while flying in ice-cold frost, Zambeccari had his two fingers frozen.

The speed of the wind was measured with the praised D. Burton's anemometric device, compiled after experiments of Robert Hooke and William

Derham (* 1657; † 1735) with windmills probably by the preacher Boerhaave's biographer William Burton M. D. at Windsor in 1730s and 1740s.[2055] While the Spanish ships sailed from Mexico to Spain for thirty days, the balloon flight could last only thirteen days, and from England to Philadelphia it was supposed to arrive under the balloon even within seven days. At the same time, Kaps from Gdansk (Danzig) found a way to keep the combustible air, that is, the hydrogen, in the balloonas long as during three months without losses,[2056] at least insofar as losses were then accurately measured. Kraškovič finished his history of aviation, undoubtedly the first such work under the pen of the Slovenian writer, with his surprisingly extensive reading list in German, French, English, Italian and Spanish languages;[2057] Kraškovič was a straight polyglot, and he began to collect material for the book about aeronautics already during his studies in Ljubljana.

Despite his book and flights in Vienna, the successful doctor of cutaneous and venereal diseases Kraškovič was not completely satisfied. He wanted to go home, which, if he moved to the then new Illyrian province, was at the same time a departure to the French Empire. The chief police commissioner of the Illyrian Provinces, the former officer serving in English army in America the freemason Louis-Toussaint de la Moussaye (* 1778, Rennes; † 1854, Paris) recommended Kraškovič to Raphael Zelli. The former intendant of Upper Austria Louis-Toussaint de la Moussaye agitated for Kraškovič's return to the Illyrian province's chair of professor in Ljubljana on December 26, 1810: "Mr. Kraskovich, a doctor of medicine, born in Illyria, glorified for his literary works, aerostat, chemistry, is famous in Vienna for the treatment of venereal diseases. For the past five years he performed a physics service in one of today's Illyrian states and now for already fourteen years he is living in Vienna. He also graduated at the University of Vienna. He would like to return to his homeland if he could hope to get there a job and a title that would at least partly compensate for his losses after leaving Vienna. Since I had the opportunity to meet him in Vienna and he turned to me for submitting a request to the Marshal (Auguste de Marmont), I would like to do this because Mr. Kraškovich boasted as an extremely talented doctor and I think it would be worth a lot if you acquire him."[2058]

Unfortunately, Kraškovič, to whom his Viennese sweetheart has just born a son, did not make the transition to the University of Ljubljana. So, the Carniolans missed the chance to enjoy Kraškovič's flights. Kraškovič was not only a great aeronaut but was also interested in the safety of pilots equipped with parachutes. Therefore, he described in detail the leap from a 145-foot-high building in Brittany in north-western France of a convicted prisoner of St. Louis (Port Louis) citadel Dominicus Dufort on September 29, 1777. Dominicus Dufort (* 1753) was sentenced for life which made him brave. He jumped under Fontagne's parachute from a height of 145 feet in Brittany.[2059] His tool was probably different from later Pierre-Joseph Fontaine's (1810-1877) parachute designed in 1845. The relative of cardinal Richelieu ex-governor Emmanuel-Armand de Vignerot du Plessis-Richelieu, duc d'Aiguillon (1720-1788), the professor Rennes of local academy and ten thousand others observed the heroic leap. Of course, Dufort (Du Fort) earned his freedom and some censorship, and the next French Emperor Napoleon III was subsequently imprisoned in the neighboring cell later.

Kraškovič's enthusiasm about aeronautics soon excited the other Carniolans. On March 28, 1798, Vodnik reported about Jurij Veha (Vega), who is "born Carniolan, as far as I know." Vodnik set Vega as the example. In his own terms, Vodnik's conditional sentence is very surprising, since Vodnik should have a better knowledge of his four years elder Ljubljana schoolmate Vega.[2060] Like Vega in Vienna or Vodnik in his Lublana Novice (Ljubljana News), even the nearly paralyzed Žiga Zois liked Montgolfier's ballooning. Therefore, Zois loved to read Cavallo's books, as Cavallo was one of the most popular Zois scientific sources. Zois also liked to watch Montgolfier's report. Upon the first contacts of the Slovenes with the French Revolutionary armies, Vodnik, otherwise not yet a convinced Napoleon's supporter, was also the spokesperson for French novelties of those days. He began to get news from Paris. On November 22, 1797, Vodnik reported on the Parisian "ride in the air" (October 22, 1797) of Charles's student

[2055] Kraškovič, 1810, 66-67.

André-Jacques Garnerin (1769-1823) when he flew under the balloon, "after heating the air to float like spruce wood on the water." In that case, above then Parisian suburb at the height 700 m, he used the first modern parachute shaped like umbrella with a diameter of 10 m tied with sixteen ropes. That parachute was not open throughout beginning of a jump. Vodnik reported to the residents of Ljubljana only one month after the event! Fourteen years earlier, the brother Montgolfier flew, and similar experiments were soon made by the people of Vienna. Vodnik certainly saw Zois's copy of the German translation of a book about Montgolfier (1783), which was subsequently evaluated to 6 kr after Zois' death. In his translation on pages 9-36, the priest Uebelacker described the history of ballooning with the achievements of Lana Terzi, Leibniz, the Dominican Joseph Galien (Gallien) in 1755 at the high school in Avignon, and Cavallo. Saint-Fond devoted his book to the French Field Marshal, and on the ninth plate he painted Lana's boat. On the remaining nine copper plates, he immortalized many details of Montgolfier's experiment, including the shape of the devices and the filling of the balloon.

In 1811, Menner and Kraškovič's dropped a hen, cat and other pets from their flying balloon during their first manned flight. They flied 70 km long, under the warmed air balloon by the Hungarian sky between Budapest and Gyöngyös: the cat survived the test and cheered the crowd or vice versa, which the Hungarians recently immortalized in their commemorative postage stamp in 1983.
Kraškovič completed a total of 65 flights. Above Pest he flew together with his colleague, doctor Menner, on June 3, 1811 and on 20 February 1812. They started their performances in Bratislava on 6 August 1811. On 15 September 1811, after a take-off at half-past six, they flew over 3 km to the Hungarian village Rajka (Ragendorf) across the Danube on the other side of Slovakian-Hungarian border near the modern triple border between Slovakia, Hungary and Austria. During their flight, both doctors onboard examined signs of altitude sickness due to diluted air.

The crowds and the archdukes with their wives applauded Kraškovič and his copilot at their launch; the latter gave a great gift to the brave aeronauts. Obviously, Kraškovič was the head of a courageous couple, since the Viennese report wrote about his flight, and Menner was only noted within the text. A hundred years later, Novi Sad newspapers quoted on the alleged Kraškovič's Baranja or Slavonian origin.[2061]

Figure 16-9: Menner's (and Kraškovič's) flight from 1811 and their brave cat on the Hungarian stamp of 1983. Later destiny of that heroic cat is still under investigations

16.2.5 Prechtl on Kraškovič

Few weeks after Napoleonic victorious battle of Marengo, early in June 1810, Kraškovič, together with Menner (Männer), exhibitedtheir balloon in the Viennese Spanish Riding School (Spanische Hofreitschule) inside Hofburg. Its diameter was 22 feet balloon and circumference 72 feet of deer skin. Behind the balloon was a safety parachute, as described by Valentin Vodnik in 1797, immediately after its first use of Paris. Upon the arrival of the prince of Neuschatel (Neuchâtel), a small balloon was launched to check the winds in higher altitudes of the atmosphere. People watched the device and could not wait for flight; on August

[2061] Kiss, 2011, 1053–1054; Kraškovič, Menner, 1811, 475; the journal *Zastava* (Novi Sad) 2. 11. 1911; Eleršek, 2010, 38.

13, 1810, Kraškovič and Menner flew for the first time from Prater in front of the courtiers and numerous audiences; Kraškovič was researching hydrogen and warmed air balloons, and he equipped one with a parachute. According to Lana Terzi's plan, he used four hollow spheres that lifted their aircraft by buoyancy. A rather unfortunate balloon performance was described professionally two weeks later and supported with advice in the leading Viennese weekly. The writer signed himself as "Pr." He was certainly Neumann's later superior Johann Joseph Ritter von Prechtl. On the mathematical basis, Prechtl studied the flight of birds resembling a possible human Icarus's event in support of Jakob Degen (* 1760, Switzerland; † 1848, Vienna), who had flown with a hydrogen balloon in 1808. In November of the same year in Prater Degen performed the first controlled flight, and finally he excelled airplanes heavier than air. From 1809 to 1810 Prechtl lectured at the Trieste Real and Navigation School as the heir of the Jesuit Franjo Orlando. At the time of Kraškovič's flight, Prechtl returned to Vienna. During the next five years, he founded the Viennese Polytechnic Institute, today's Viennese Technical University. He also worked on gas lighting and vacuum techniques at the dawn of the invention of the cathode-ray tube.

Prechtl explicitly described how Kraškovič first sent to the atmosphere a smaller balloon that soon disappeared behind the horizon to warm up the spectators and check the wind in upper layers of the atmosphere. They lifted their second smaller balloon along with a tiny parachute; at a small height, a parachute separated from the balloon and brought an undamaged egg in the basket to the ground. Three other small balloons connected with threads turned with the wind towards the north; the middle one of them was filled with a gaseous hydrogen mixture with air and the other two were filled with hydrogen.[2062] At a considerable height, the middle balloon entered the stage, burst open and exploded. Hardly the spectators recovered from the rebuke when the larger balloon was followed by a small parachute, which the wind also drove up north to the edge of the horizon behind the trees by the banks of Danube river; only there a parachute was by itself separated from the balloon, without any spectators being able to see most of the events. Then the machine was raised in the form of a small boat made of taffeta, coated by linseed oil (wood finish), under four significantly big balloons, with which Kraškovič was supposed to realize the idea of Lana Terzi and save Lana's flight problem. On this occasion, their too easily announced alleged airship was left to fate, as it soon lost its balance and was routinely steeped downwards. The roof with a mast made according to the Lana's depiction turned to the ground, worn by the uneven winding of balloons, like its predecessors among the balloons. The main fault of Kraškovič's design of Lana's ideas was the uneven shipping of four balloons which were supposed to stay in the same horizontal plane. Because of winds they did not, which ruined the balance of the craft. Prechtl did not specifically report on the fillings of those balloons which could have been vacuumized as Lana suggested in the first place. In the end, the main balloon with a capacity of 4,200 cubic feet (150 m^3) was launched; it split many carefully designed balloons, which dropped individually from the height to let their animals downwards. One of these balloons, unfortunately, had a hole on the upper side, through which it lost a quarter of its hydrogen filament. In the absence of a new filler for the replacement of lost gas, this flaky balloon floated like a loose sail. It had a high flight, while its lifting force (buoyancy) balanced the weight of its own load.

Upon the description of these Kraškovič's experiments, the observer Prechtl afforded some benevolent advices. He stressed the lack of tension in the balloon, which is related to external weather conditions; the increased concern is necessary for large aerospace projects, because in this new field of Kraškovič's research with balloons, the advanced learned data quickly change the previous physical knowledges and beliefs. Kraškovič and Menner performed their preliminary experiments with the parachute in absolute windless tranquility; they hoped for the case of windless cloudlessness at the high altitude from which the parachute could descend after separation from the balloon. In such windless quietness, the experiment would undoubtedly be perfectly displayed to the viewers. Due to stronger winds on higher elevations, the balloon package above Prater quickly deviated from the visible field of the spectators towards the north. In that case Kraškovič should have shortened the parachute by at least a half, so that the balloon could reach the desired height, before the parachute would separate from the balloon by

[2062] Kraškovič, Menner, 1810, 287; Eleršek, 2010, 39.

itself, tear off, and drop. However, if the upper winds did not drive the parachute balloons so urgently, those experiments would lose the glamor for spectators. Also, a balloon filled with Oxyhydrogen (Knallgas) had to fall due to the wind. An experiment to make Lana's ideas possible could be happily carried out as soon as Kraškovič took to his heart that the center of gravity of the entire plane should be distributed to the extremity of the ship's shaft. To ensure the success of the experiment even more, he should use the slightly larger four lifting balloons. The shaft of the ship must be longer and coated with hardwood so that it can be lifted by the buoyant (pulling) balloon force without any damage. The outer mast must be lightweight, made only from scratched paper. By any other construction, the ship would be rocking and rolling for so long until the center of gravity of the entire airship dropped down to the ground and the excess weight of the mast roof. In addition, it can be very difficult, if not impossible, to make and fill all four balloons so equally to have the same buoyancy; even with the same equally strong evaporation or leakage of gas stored in balloons, the buoyancy of individual balloons is increasingly unevenly lost in the air, so that the ship is pulled from the desired horizontal position.[2063]

In contrast to the filled balloons, Lana's four copper vacuum balloons that Lana himself proposed to lift the airship would have always exactly same buoyancy force if they could only be made. Even nowadays, two centuries later, the unresolved problem remains the pumping out towards the total vacuum inside the balloon framework, which would withstand a huge external pressure.

Finally, Prechtl thoughtfully contemplated his opinion about the failed experiment with a large balloon: when any unpredictable case causes an accident, its relaxation is not only in our power. Such coincidences can be prevented from large aerospace shows with the utmost care and caution. Inserting a filler into a balloon is very important for the operation of a composite light aircraft, but it is subject to damage. It is understandable that it does not seem fine to damage the needs and expectations of the gathered viewers. Furthermore, it is not possible to publicly raise a large balloon without a recalculated charge of an excess material with a stock in the extent of at least half of the total filler; so, we need to double the filler with the filling device.

Prechtl advised the excessive filling as a protection from losses due to leakage of the balloon but he did not specifically consider reductions of pressure in higher atmospheric layers.

Figure 16-10: Austrian stamp showing the flight of Johann Georg Stuwer (Stubenrauch, * 1732 Oberliezheim in Swabia; † 1804 Vienna) over the Viennese Prater on July 6, 1784, before Kraškovič came to study in the imperial city. Of course, the flight was viewed by Jurij Vega, who was confirmed at the second regiment of the imperial artillery on 17 April 1780.

In addition to the fatal shreds of the balloon, there is another coincidence that can only interfere with the corresponding charge and can also occur in the case of a large surplus of the filling substances. During charging with sulfuric acid acquired by pouring the water on glowing iron parts for production of hydrogen, problems with zinc ointment placed in the back of the filling can occur. With all caution, the researcher will be uncomfortable with this experiment, so that his balloon could be affected; boarding would likely became uneasy. If everything is good at the scene,

[2063] Kraškovič, Menner, 1810, 288; Eleršek, 2010, 39.

then the costs will not easily exceed the remaining stocks of the filling substance or the potential drop in the purchased supplies. When we consider everything, we see that the course of this experiment, with the care of his majesty of the emperor, by which Kraškovič became accessible to the prescribed certificates, fully justified Kraškovič's personal flight in a manned balloon. Moreover, on this occasion, it is not possible to deny that the spectators of the Viennese audience are honorable and exemplary during such failures. While in other major cities the folks usually follow similar misfortunes with stormy scenes, the Viennese people seem barely dissatisfied not to see what they were promised for their money. They take it diligently, they move away from the scene peacefully, but when they get a high voice, it is an expression of sympathy with the entrepreneur,[2064] Kraškovič.

For the end, Prechtl politely greeted the people of Vienna. At the same time, he prophetically advised and announced the flights of Kraškovič and Menner in a manned balloon, which followed a few months later. Of course, the aeronauts were no longer such special useful feature a quarter of a century after Montgolfier, but only a few of them were born in the Habsburg monarchy like Kraškovič. Certainly, a great money and prestige was involved in then aeronautics, therefore Prechtl demanded his own shares.

Kraškovič carried his sixth flight over the Danube in a balloon on 20 November 1814, according to Laibacher Wochenblatt report published on 14. 12. 1814;[2065] the report noted Kraškovič's testimony of a scene from his youth on the Adriatic Sea, perhaps during his service in Zadar. In a special note, Kraškovič was emphasized as a born Carniolan; he flew 10 km north-west at a height of 1 km. He did not dare to get higher because of the cautionary example of James Ballerum James Sadler (* 1753; † 1828) whose valve got frozen during his flight. Later, in the beginning of October 1815, Kraškovič flew to delight the Peace Congress in Vienna.[2066]

Kraškovič soon got excited imitators among Slovenes. Among the most expensive physical devices at the gymnasium in Koper, a rubber balloon was purchased with a tap of brass, which was probably intended for exploring gases. It was bought for 58 florins or 4.5 DM in 1867. In 1904/05, Maks Samec the Younger (* June 27, 1881; † June 1, 1964) began to fly with balloons for research purposes as well. On 24th of May 1908, at 11:55, he rose under the double-manned balloon, which was administered by Ludwig's son dr. Arthur Boltzmann (* 1881; † 1952). The copilot Samec checked how the luminosity is increasing with height.[2067] During the exploration of balloon flights, the Ljubljana baron Codelli identified the advantages of their size, and in 1910 on five typed pages he designed a huge steel balloon nicknamed Dreadnought following the idea of Ober-lieutenant Wallach. The imposing balloon was 1 km long with a diameter of 100 m designed for the transport of 20 000 passengers at the velocity of 160 km/h. Sorry to say, no passenger ever embarked. Those designs resembling the unfortunate Titanic were appealing similarly as their modern copies of spacecrafts of Jeff Bezos or Elon Musk.

16.2.6 Inner Carniolan Kraškovič in Dubrovnik

In the late 1817, Kraškovič published a translation of Benjamin Waterhouse's (* 1754; † 1846) pamphlet against smoking and drinking spirits, where he signed as M. Kraskowitz.[2068] Of course, Kraškovič hated the smoking because it could become fatal during his flights under balloons filled with hydrogen. Like Kraškovič, the American professor Waterhouse of Harvard published a paper about the vaccination in 1800. Kraškovič’s colleague in Dubrovnik Dr. Luca Stulli (* 1772; † 1828) used to be the Bolognese student in the classes of Luigi Galvani, the anatomist Carlo Mondini (* 1729, Bologna; † 1803) and Gaetano Gaspar Uttini (1741-1817) as the initiator of the vaccination in Bologna in 1806. Dr. Luca Stulli was the first to carry out Jenner’s vaccination in Dubrovnik with the vaccine of Luigi Aloys Caren (* 1766, Pavia; † 1810, Vienna) in 1800. In April 1799 with the confirmation next year Stulli was employed as one five physicists responsible for the city hospital. After his

Bolognese promotion in 1796, Stulli visited Felice Fontana in Florence. Stulli showed to the initiator of neurology Domenico Cotugno (* 1734, Ruvo di Puglia; † 1822, Naples) in Naples the first Galvanic experiment outside the narrow circle of Galvani's own experiments with galvanic electricity.[2069] In 1772, Felice Fontana as a physicist at the court of future Emperor the Toscana Archduke Leopold II in Florence, discovered the adsorption of gases on hot wood charcoal, which we nowadays know as getters. He was the priest and brother of the mathematician of the Piarist order. He worked as a professor of logic and physics in Pisa and then in Florence. Fontana's gettering was assembled by extinguishing the burner without contact with the outside air. With this, the adsorption of charcoal has been saved for the air in the recipient. Laibacher Wochenblatt reported on the importance of accurate measurements of the density of various gases acquired by the experiments of the priest Fontana from Tuscany after the report on the dissertation of Mustel from Rouen on the circulation of liquids in plants (Krauten).[2070] François Georges Mustel (1719 Rouen-1803 Rouen) was a promotor of cultivated potatoes in Normandy and the member of Rouen royal agricultural society from 1771 as well as the member of RS of London. His *Traité théorique et pratique de la végétation, contenant plusieurs expériences nouvelles et démonstratives sur l'économie végétale et sur la culture des arbres, par M. Mustel* was translated in Italian and English language in Phil. Trans. in 1773/74. He must not be confused with the younger Nicolas-Alexandre Mustel (1724/36-1804/06).

In 1808, Stulli became a vaccination supervisor in Dubrovnik. On 23 July 1822, the Dubrovnik district physicist (kreisarzt, kreisphysicus, protomedicus) Kraskovich reported to the Dubrovnik District Office and to the governor of the allegedly chemical volcanic causes of detonation phenomena resembling the earthquake on the island of Mljet (Meleda). In the coming months, the problems of Mljet has interested the proponent of electrical theories Dalmatian proto-medic in Zadar dr. Guglielmo Menis (Vilim, William, Willelmo, * 1790 Artegna north of Udine, † 1850 Trieste) in his letter sent to the Dubrovnik doctor Stulli, published at the end of 1823. The event in Mljet was also discussed by the Dalmatian marine engineer temporary district engineer for public construction, water and roads in Dubrovnik Antonio Luigi de Romanò (Romano) in his report for the provisional director of the factory in Dubrovnik and in his discussions of opinions of Kraškovič, Stulli, Galvani's nephew Giuseppe Aldini and others in his Venetian book in 1828. The astronomer Johann von Littrow tried to offer his solutions and the young later leading Viennese physicist Andreas Baumgartner (* 1793; † 1865) promoted his own ideas.

Figure 16-11: Kraškovič and Menner in balloons at Prater in honor of the Viennese Peace Congress in 1815 on the drawing of those times

Arago became interested in that strange drumming under the island of Mljet after he received Stulli's letter and the attached book. The Viennese authorities invited into the research the geologist Scipio Breislak, an inspector for potassium nitrate and gunpowder in Milan, and the investigator of electromagnetism the Barnabite priest Pietro Configliachi (* 1777, Milano; † 1844, Cernobbio). Configliachi was the pupil and successor of A. Volta in Pavia as well as researcher of the human fish Proteus. According to the book of Paul Partsh (* 1791; † 1856) from the Viennese Mineralogical Cabinet issued in 1826, Kraskovich have died in the meantime;[2071] he was replaced by Joseph Derchich (Derčić) as a Dubrovnik district physicist. Due to the increased drumming, all islanders from Mljet escaped to the Dalmatian coast in August and September 1823, and the professor at the Viennese Polytechnic Institute Franz Riepl and Partsch came to investigate in Mljet for the entire month of 1824. The strange noises started on March 22, 1822 and in March

1824. They lasted until 3 September 1825 with a shorter repetition of 18 February 1826.[2072]

There is nothing fairer than the old lady death. The close encounter with her revealed the background of the many travels of the first Slovenian aviator. He presented his life story outside of his flying glory and his vacuum techniques developed for filling his hydrogen balloons.

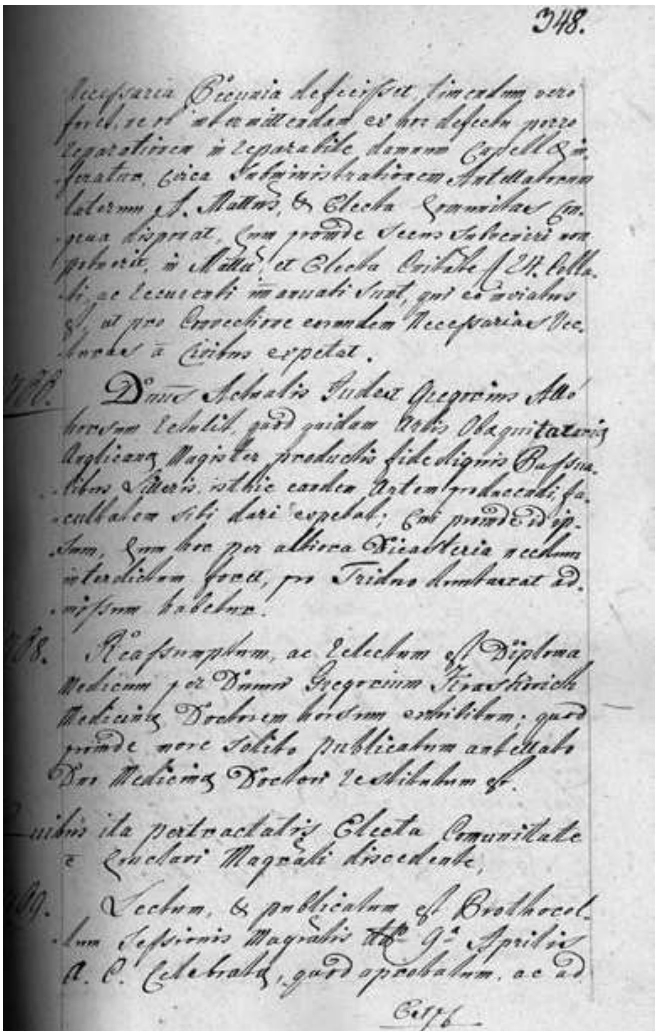

Figure 16-12: A honorary diploma of Gregor Kraškovič in Varaždin was presented in 1799 (HR-DAVŽ-2, 1799, p. 348, No. 768)

The first Slovene balloonist Gregor Kraškovič (* 3. 3. 1767, Studenec of Bloke in today's Župan (Mayor's) house, † 1823, Pale by Dubrovnik) was a younger contemporary of the second famous Slovenian physician, Balthasar Hacquet (* 1739/1745; † 1815, Vienna). Hacquet came to Idrija a couple of months before Kraškovič peeped into the world. Hacquet left Ljubljana just before Kraškovič started the last year of his lower studies there. Thus, both scholars met each other only in Vienna in the last five years of Hacquet's life; they did not live very far from each other at all, and Hacquet was able to see the well-visited Kraškovič's flights with his balloons during his stay in Vienna, which Kraškovič filled with the latest novelties of then vacuum technique by the exclamations of admiring viewers.

16.2.7 Testament

On 2. 1. 1823 a priest walked to Pile beside the city walls of the then Dubrovnik. He brought together prominent Catholic and Orthodox traders from the neighborhood to witness an oral transmission to the last wish of a gravely sick powerless Dubrovnik district doctor and researcher of vacuum balloon filling techniques, Gregor Kraškovič. The good-natured guests were astonished by the performance of a teenager Gregor Hanner (* 20 August 1807, Vienna). The kid was the high schoolboy at local gymnasium, who quite surprised the guests after his godfather Kraškovič declared him as his natural son and the only heir.

Although Kraškovič's fellow medical practitioners were not at his bedside, Dubrovnik's ancient dwellings ranged from stories from the newly discovered details of the life of a Slovenian doctor, world-renowned innovator of modern vacuum techniques for balloon filling and barometric measurements of heights. He had no help available in this world and soon he closed his eyes forever at Pile in four in the morning on 5 January 1823.

Kraškovič, as a careful father, matriculated his son to the Piarists' Dubrovnik lower studies, while at the same time he invited the kid to spend his time in pharmacy examining his surgical and vacuum techniques in the belief that the boy will later study those sciences in Vienna. The plan, after all, was somewhat confused later, because instead of surgery in Vienna, Hanner preferred to study philosophy and theology. Kraškovič worked closely with the teachers of his son in those times. He also enclosed a letter dated 15 June 1822, signed on 17 June 1822 to his letter mailed from the island of Lastovo; it was a one-sided letter from Mljet addressed to the Dubrovnik Archbishopric, accompanied by reports from a local preacher and bishop from the secondary

[2072] Cournot, 1827, 247–249.

school in Dubrovnik. The great attention was drawn to the report of Mr. Krašković's physics report on detonations in Mljet[2073] related to underground vacuum and electricity. On 16 July 1822, the rector and the prefect of the Piarist school in Dubrovnik, a linguist and archaeologist Francesco Maria Appendini (1768 Poirino near Torino–1837 Zadar) from Dubrovnik reported to the Dubrovnik Governorate. He wrote a bilateral one-page letter about the detonations on the island of Mljet, which began on June 24, 1822. They had already ceased; on the first page he mentioned the influence of the island caves. Francesco Maria Appendini was a student of Dubrovnik native Marko Faustin Galjuf. In 1803 Francesco Maria Appendini published his *"Notizie Istorico-Critiche Sulla Antichita, Storia, e Letteratura de' Ragusei"* in two volumes. Together with his brother the professor of mathematics Piarist Urbano Appendini (1777 Poirino-1834 Zadar), he organized the teacher's preparatory school in Zadar. Francesco Maria Appendini's letter about Mljet was registered on 19. 7. 1822 and on 2. 8. 1822 with the signature of Giovanni Tromba, the commissioner of the Dubrovnik Archdiocese. After his studies of mathematics in Rome and astronomy in Firenze, Urbano Appendini taught mathematics in Dubrovnik in 1795-1824, until he became the head of Zadar Lyceum and soon the head of all gymnasiums in Dalmatia. His successor in Dubrovnik at that time was the secular pastor Giovanni Battista Campsi (Ivan) who became the professor of mathematics, natural sciences and physics in Dubrovnik.[2074] Campsi was probably a native from today's Shkodra in Albania, but obviously he did not promote enough Hanner's interest in vacuum techniques.

All his times of studies of gymnasiums and during his studies in Vienna Hanner used primarily his father's legacy; Krašković knew too well how well it suits to the growing pupil, since he himself was compelled to grumble many doors of the wealthy to get through his studies, and financing of his balloon gaskets and valves. In this regard, Krašković also had an extremely happy hand in choosing a caretaker for his son's legacy. His friend Franc Ludvik Regner knight Bleileben (Franz Ludwig Regnier Ritter von Bleyleben, Vjenceslav Nepomuk, * 1795 Chotimir in Brno city-district; † 23. 12. 1854 Nin by Zadar) achieved even the payment of 600 florins as Krašković's last annual salary for Hanner, although Krašković died immediately in the beginning of 1823. At the same time, Regner provided a regular supply of money for the maintenance of Krašković's son. In 1843-1844, Franz Ludwig Regner Ritter von Bleyleben was a district commissary of Zadar.[2075] The family Regner Bleyleben achieved the noble rank under the emperor Rudolf II and settled in Moravia.

16.2.8 Books on Vacuum Techniques

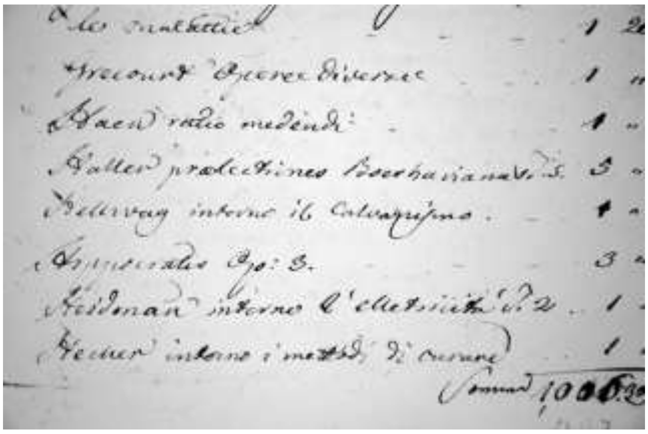

Figure 16-13: Heidmann and Hellwag's manual for the study of electrical and vacuum phenomena, listed in Krašković's legacy on the second and fourth place, counting from the bottom. Above them are the books of the Boerhaave's pupils (HR DADU 156, Sez. E, Fasc. VI, No. 45).

In Krašković's legacy, a collection of mainly professional books for medicine and vacuum techniques was selected. They were recorded in his settlement of Pile; the members of the official commission catalogued Krašković's gold after less than a week, and they catalogued his books and other belongings one month after Krašković's death on February 5, 1823. The legacy included unusually many goldsmiths' products, table and portable watches, telescope and medical devices, designed and based on modern achievements in vacuum techniques; there were also many expected personal things.

2073 HR DADU 81, 1822, Tern. VII, noted on no. 4070/374 and no. 345.
2074 HR DADU 81, 1822, Tern. VII, no. 297; *Almanacco*, 1819, 122.

2075 *Gazzetta (ufficiale) di Zara*, 6. 2. 1835, p. 42; Wagner, Kudler, Dolinar (Dolliner), 1839, 495; *Kayserlicher Und Königlicher Wie auch Ertzhertzoglicher Dann Dero Haupt- und Residentz-Stadt Wien Staats- und Standes-Calender, Auf das Gnaden-reiche Jahr ... Mit einem Schematismo gezieret. Cum privilegio Caesareo speciali*. Johann Baptist Schönwetter, 1843: 391, 1844: 396.

Some items from the legacy were controversial, since Kraškovič was not the owner of his Dubrovnik flat and some vacuum and other accessories were available to him because of his profession; authorities were trying to get them back when they installed a new physician as Kraškovič's replacement. Regner as a manager showed a tremendous degree of commitment to acquire as much as possible for the son of his late friend Kraškovič.

For his scientific career, of course, the most interesting were Kraškovič's books focused on gases, vacuum and electricity. Among dozens of medical and other aids, basically, the manuals on which Kraškovič relied as a vacuum researcher and a chemist are of interest here. On the eighth page, the commission began a list of his books under the subtitle Libri, Carte Geografiche e Globi Terrestri. There were eight maps, according to the note, they were written in Kraškovič's language.[2076] Of course, it is difficult to imagine something Slovenian in those times before the map of Peter Kozler, which came out only a quarter of a century later. Kraškovič's domestic language was therefore probably used as a designation for German language. The commission followed their notes with two small globes of the Earth, each rated for one forint. Only then did the townspeople commission begin their listing of books in alphabetical order, since the first in the row was the work of Venetian Prospero Alpini (* 1553; † 1617) with his two books, among which the second was his famous Medicina Egiptiorum Libri 4. After Arnoldi's English grammar, there was Avicenna's Arabic Medicine which followed principles and canons in two copies that show Kraškovič's extraordinary classical education. Avicenna, in contrast to Aristotle, proved the possibility of motions in a vacuum.

Kraškovič has purchased numerous works on venereal and female diseases, including Johann Friedrich Fritze's and Giambattista Monteggia's[2077] books; of course, Kraškovič did not miss the book of vaccinating of his Swiss friend Jean De Carro,[2078] who moved to the Imperial city in 1795 and sent the vaccine from Vienna to Varaždin for Kraškovič.[2079] Kraškovič bought the books of Boerhaave's pupils: the *Ratio medendi in nosocomio practico Vindobonensi* of Anton de Haen (* 1704; † 1776) estimated at 1 forints, Albrecht Haller's Praelectiones Boerhavinas and van Swieten's comments on Boerhaave. Herman Boerhaave together with Musschenbroek's family developed vacuum pumps in Leyden, and in 1712 he started using a vacuum pump in his chemical laboratory.

Kraškovič read the great famous work of Christoph Friedrich Hellwag (* 1754; † 1835) about the pioneering healings with electricity. Hellwag received his doctorate in Tübingen.[2080] He became the pioneer of Jenner's vaccination in the south of Schleswig-Holstein,[2081] much like Kraškovič in Varaždin. Hellwag was interested in Newton's theory of colors.[2082] He believed that we did not

have to do with seven simple colors, but with only four simple colors or rays of different refractions. In doing so, he refused certain ideas of the Jesuits A. Kircher, Newton, Goethe's Jesuit predecessor Louis Bertrand Castel (* 1688; † 1757), and Leonhard Euler. He corresponded with Goethe and Kant, and he published a botanical study of a geranium plant in 1776. Kraškovič bought Hellwag’s 136 pages long book with a sketch about the pioneering medical treatments with electricity. In 1802 Hellwag’s writing was supplemented by the son of the philosopher Friedrich Heinrich Jacobi, Maximilian Jacobi (* 1775; † 1858); in those days, Maximilian Jacobi, along with Hellwag was a doctor in the city of Eutin in Ostholstein, as Goethe’s correspondent and initiator of the psychological studies of delusions. Hellwag and Jakobi described their experience in connecting patients to Volta’s batteries and introduced developed vacuum techniques.[2083] In those times still poorly tested treatment with the help of Volta's batteries certainly did not always bring just the innocent pain to the obedient patients.

Figure 16-15: Jurij Vega as an early purchaser of Heidmann’s book, noted in the 9th line of the second part of Heidmann’s Manual on Electricity and Vacuum Technology of the Year 1799. Kraškovič as well as Vega used that book.

In 1818, Hellwag wrote about Euclid's eleventh principle, which is nowadays rather quoted as the fifth postulate. In the following decades, debates on the fifth postulate opened the door to modern non-Euclidean geometry. In 1824, Hellwag published work on the movements in a living and inanimate world.[2084]

Kraškovič certainly also read classical Hippocratic books in three volumes, estimated at 3 forints. Most of all, Kraškovič liked the textbook of his co-worker, the Viennese physician Johann Florian Anton Heidmann written against Volta in support of Galvani’s theory of electricity.[2085] Heidmann dedicated the book to a long-time professor of mathematics and a Jesuit writer of the history of the Ljubljana College in the period from 1772 to 1778, Joseph Jakob Liberatus Maffei von Glattfort (* August 15, 1742, Gorizia, † 1807, Vienna). Maffei was assistant to Gabriel Gruber and benefactor of Jurij Vega. The

freemason Maffei was very popular among his students, and Vega also devoted to Maffei his second edition of the logarithmic-trigonometric manual in 1800. Maffei used to be a tutor of mechanics and physics, and then even the secretary of the later Field Marshal of Prince Maria Colloredo-Walsey; just before the publication of Heidmann's work, he became a pontiff in Old Boleslav, northeast of Prague in the crownlands of the Bohemian kingdom. the freemason Maffei was really very popular among his students and Kraškovič might have met him.

Heidmann was promoted at the Viennese Medical School in 1797, just after Kraškovič. In 1804, as a member of the Viennese Medical School, Heidmann lodged at Weyburggasse number 964[2086] in the very center of the city east of Graben, not far from the then-Kraškovič's office in the district of Wieden. In 1804, after Volta's inventions of batteries, Heidmann published a study of the use of electroplating electricity to check the whereabouts of apparently dead people. From a modern point of view, he worked on quite cruel experiments with strong electrical currents applied to animals,[2087] but the views of those days were different. He devoted his book to his and Kraškovič's teacher Georg Prochaska. In 1837, Heidmann was among the first members of the Viennese Medical Society and served as its first secretary.

Heidmann assumed that the operation of electricity in a vacuum induces most of the chemical phenomena;[2088] the assumption was further exacerbated by subsequent researchers, so that we blame local surface disorder of outwards neutral electric charges for many biological effects nowadays.[2089]

Heidmann quoted the inventor of the vacuum pump Otto Guericke[2090] as well as the first serious historian of vacuum devices and electrical engineering, Joseph Priestley. Heidmann was particularly interested in Voltaic inventions, as was Beccaria, Euler's Berliner student Johan Carl Wilcke's (* 1732 Wismar; † 1796 Stockholm) electrophorus of 1762 and Wilcke's eight years older Russian-German mentor-colleague Franc Aepinus. They all explored Volta's electrophorus. Heidmann knew about the publications of former Ljubljana physicist and rector Ambschell about electricity in glass. Heidmann saw the electrophorus in Simon Eberle's (* 1756; † 24 December 1827, Vienna) physics and natural science cabinet established in 1795. Shortly thereafter, in 1801, the poor priest Eberle was quickly retired for the sake of his excessive spending of money, certainly committed by the purchases of expensive electrophorus and vacuum pumps.

Of course, Eberle was among the pre-subscribers of the second part of Heidmann's book on March 25, 1799, along with the artillery major Jurij Vega.[2091] Heidmann was particularly interested in the theory of electrophorus of Jan Ingenhousz (* 1730; † 1799).[2092] Together with other papers of those years, it was based on the early achievements of the Hallerstein's Pekingese Jesuits. Heidmann summaries of the experiments of Jacques Alexandre Cesar Charles and others with the oxidation of metals by electric sparks in a vacuum and inflammable air (hydrogen)[2093] were of great interest to Kraškovič when he was looking for suitable charges for his hydrogen balloons. Heidmann obtained very pure hydrogen for his electrodynamic experiments in the same way as Kraškovič for his balloons, that is, by oxidation of iron or zinc with sulfuric acid, which he still named as vitriolic acid according to old habit of medieval times. He evacuated the receiver to achieve the lower pressure of 1/168 bar, which was then an enviable grade of vacuum. The iron sulphides like pyrite also attracted a magnet in an empty space, as was proved by the French mineralogist Jean-Claude Delamétherie (Métherie, * 1734; † 1817) beyond the then-war-colored Iron Curtain in Paris. In vacuum experiments, Heidmann set up one inch long golden conductor under a 42 cm cubic inch (0.7 liter) bell and let the current of the heavily charged battery through it to cause the oxidation of the surface of the conductor.
