*Keywords*: Beurling's prime system, Squarefree, Abundant numbers, Deficient numbers and ωp-numbers

## **1. Introduction**

Let x be a natural number, and  $\sigma(x)$  be the sum of its divisors. Then  $x$  is called abundant, deficient and perfect if  $\Delta(x) = \sigma(x) - 2x >$ 1,  $\nabla(x) = 2x - \sigma(x) = -\Delta(x)$  and  $\Delta(x) = 0$ respectively. We say that an abundant number  $x$  which can be express as a sum of distinct proper divisors is semiperfect  $\int sp$ number in this paper). We say x is weird  $(\omega$ number in this paper) if  $x$  is abundant and not *sp*-number. We call a  $\omega$ -number x primitive  $(\omega_p$ -number in this paper) if it is not a multiple of any smaller  $\omega$ -number. This introduction also addresses some details from lectures about Beurling prime system

A B S T R A C T

Primitive weird number is weird number which are not a multiple of any smaller weird numbers. The goal of this work is to generate a square-free primitive weird number  $x = c \prod_{i=1}^{n} q_i$  where  $\{q_i\}_{i=1}^{n}$  be an increasing sequence of prime numbers such that  $q_1$  is greater than  $\prod_{j=1}^r (\overline{q}_j + 1)$  and  $c = \prod_{j=1}^r \overline{q}_j$  is deficient number with  $n$  greater than 1, to be able to use this special form to enhancing the classic bounds of  $\Omega$ -results for  $(N_3 - \tau x)$ .

> and the generalized Chebyshev's function  $\Psi_{3}(x)$  which would be the integer part of x minus 1. That is:

$$
\Psi_{3}(x) = x + O(1)
$$

Where the Beurling prime system is very closed to being discrete system and investigating how regular the corresponding generalized counting function of integers  $N<sub>3</sub>$ to be. Now we move our attention to address an O-results and Ω-results for  $(N_3(x) - \tau x)$ which has been investigated by number of writers (for example [1]) as follows:

On the Riemann Hypothesis the upper bound for  $(N_3(x) - \tau x)$  can be improved to:

$$
N_3(x) - \tau x = O\left(x \exp\left\{-\frac{a \log x \log_3 x}{\log_2 x}\right\}\right), \qquad \text{for}
$$
  
every  $a < 0.25$ .

Furthermore, they also find lower bound for  $(N_3(x) - \tau x)$ , they have:

$$
N_3(x) - \tau x = \Omega(xe^{-\frac{a \log x \log_4 x}{\log_3 x}})
$$
 for  
every  $a > 1$ ,

As a comparison between O-results on the Riemann Hypothesis and  $Ω$ -results, they have

$$
N_3(x) - \tau x = \Omega \left( x \exp\{-\frac{b \log x \log_4 x}{\log_3 x} \} \right)
$$
 for  
every  $b > 1$ ,

$$
N_3(x) - \tau x \ll x \exp\{-\frac{c \log x \log_3 x}{\log_2 x}\}\
$$
 for  
every  $c < \frac{1}{4}$ .

This shows that there is a small gap between these results which reflects the great difficulty in determining the behaviors of  $\zeta_3(\sigma + it)$  in the strip  $0.5 < \sigma < 1$ . In a previous paper [2] we have been restricted the gap between the error terms of  $Ω$ -results for  $(N_3 - \tau x)$  (where the Ω-results are generalized Ω-results for  $N_p$  as counting function of Beurling) and the error terms of O-results for  $(N - \tau x)$  on R.H. and we get:

$$
N_3(x) - \tau x = \Omega(xe^{-ck_x})
$$
 for every  $c > 1$ ,

Where

$$
k_x = \log x \sqrt{\frac{\log_4 x}{\log_3 x}}.
$$

The aim of this work is to generate  $\omega_p$ number from square-free prime numbers and using this special form to enhancing the upper bound of  $(N_3 - \tau x)$  using the same approach as in [2].

 In this section we provide a way for generate  $\omega_p$ -number from square-free prime numbers, so we start with:

# **2.1. Lemma**

Let  $c = \prod_{j=1}^r \overline{q}_j$  with  $\Delta(c) \le -1$  (c to be deficient number) and there exists a prime  $q > \overline{q_r}$  such that  $cq$  is abundant, then for  $n > 0$  there are an increasing sequence of prime numbers  $\{q_i\}_{i=1}^n$  such that  $q_1 > \overline{q_r}$ ,  $c \prod_{i=1}^{n} q_i$  is abundant and  $c \prod_{i=1}^{s} q_i$  is deficient for all  $s < n$ . Hence  $x = c \prod_{i=1}^{n} q_i$  is PA-number.

# **Proof:**

To prove that  $x$  is PA-number (i.e.  $x$  is abundant and  $c \prod_{i=1}^{s} q_i$  is deficient for all  $1 \leq s < n$ ). If  $s = 1$  then  $x = cq_1$  is PAnumber, by [3, lemma 2.1] we get  $x = cq_1$  is abundant and since for all  $d | x$  is deficient (either  $d = q_1$  or  $d | c$  which are deficient by [3, lemma 2.2]).

Now, for  $s = 2$ , let  $x = c_1 q_2$  where  $c_1 = cq_1$ . By  $[3, \text{ lemma } 4.1]$  we have x is abundant. Now, If there is divisor  $d$  of  $x$  then either  $d$ divide  $c_1$  or  $d = q_2$ . So when  $d | c_1$  either  $d = q_1$  or  $d/c$ . Therefore, d is deficient by [3, lemma 2.2]. Continue in this manner applying corollary 2.11 in [4] for n-times we get that x is PA-number.

# **2.2. Proposition**

Let  $c = \prod_{j=1}^r \overline{q}_j$  such that  $\Delta(c) \leq -1$  (c to be deficient number) and  $n$  greater than 1. Let  ${q_i}_{i=1}^n$  be an increasing sequence of prime numbers such that  $q_1$  is greater than  $\prod_{j=1}^r (\overline{q}_j + 1)$ . Let

$$
\ell = flow(\frac{q_1 - \prod_{j=1}^r(\overline{q}_j+1)}{q_n - q_1}).
$$

Let  $x = c \prod_{i=1}^{n} q_i$  and

# **2. Generating**  $\omega_p$ **-number**

$$
\mathcal{K} = \bigcup_{k=0}^{\ell} \left\{ a \in \mathbb{N} | k q_n + \prod_{j=1}^{r} (\overline{q}_j + 1) < a \right\}
$$
\n
$$
< (k+1)q_1
$$

Then for all  $a \in \mathcal{K}$ , a cannot be expressible as a sum of distinct divisors of  $x$ .

#### **Proof:**

Since  $\prod_{j=1}^r (\overline{q}_j + 1) + 1 \le q_1$ , then K is not empty set. If

$$
\overline{\ell} < \frac{q_1 - \prod_{j=1}^r (\overline{q}_j + 1)}{q_n - q_1}
$$

So,

$$
\prod_{j=1}^r (\overline{q}_j + 1) + \overline{\ell} q_n < (\overline{\ell} + 1) q_1.
$$

Let  $k \leq \ell$  and let a belongs to  $\mathcal{K}$ , (i.e.  $\prod_{j=1}^r (\bar{q}_j + 1) + k q_n < a < (k+1)q_1$ . We went to prove that  $a \neq \sum_{b|x} b$  (sum of distinct divisors of  $x$ ).

Suppose that  $a = \sum_{b|x} b$  (sum of distinct divisors of  $x$ ). As

$$
a < (k+1)q_1 < \left(\overline{\ell} + 1\right)q_1 < \left(\frac{q_1}{2} + 1\right) < q_1^2.
$$

So these divisors take one of the forms  $\bar{q}q_1$  or  $\overline{q}$  with  $\overline{q}|c$  and  $\overline{q}$  belongs to the set  $\{\overline{q_1}, \overline{q_2}, \ldots, \overline{q_r}\}.$ 

For  $a = \sum_{j=1}^{N} \overline{q}_j q_1 + \sum_{i=1}^{M} \widetilde{q}_i$  where  $\{\widetilde{q}_k\}_{i=1}^{M}$  is the set of distinct divisors of  $c$ . As  $a < (k+1)q_1$ , then  $\sum_{j=1}^{N} \overline{q}_j$  must be less than or equal  $k$ . So

$$
\sum_{i=1}^{M} \tilde{q}_i = a - \sum_{j=1}^{N} \bar{q}_j q_1 > a - k q_n > \prod_{j=1}^{r} (\bar{q}_j + 1)
$$

This is a contradiction with our assumption. Hence  $a \neq \sum_{b|x} b$  (*b* distinct divisors of *x*). Therefore, there is no elements in  $K$  can be expressed as a sum of distinct divisors of  $x$ .

#### **2.3. Theorem**

Let  $c = \prod_{j=1}^r \overline{q}_j$ that  $\Delta(c) \leq -1$ (deficient number) and there exists a prime  $q > \overline{q_r}$  such that  $cq$  is abundant. And for n greater than 1, let  $\{q_i\}_{i=1}^n$  be an increasing sequence of prime numbers such that  $q_1$  is greater than  $\prod_{j=1}^r (\overline{q}_j + 1)$ . Let

$$
x=c\prod_{i=1}^n q_i.
$$

If x is abundant and  $\Delta(x)$  belongs to  $\mathcal K$ , then x is  $\omega_{p}$ -number.

### **Proof:**

If  $n = 2$ , then

To prove that x is  $\omega_p$ -number (i.e. x is  $\omega$ numbers and PA-numbers).

First we prove that x is  $\omega$ -number by using lemma 2 in [5] and as  $\Delta(x)$  belongs to  $\mathcal K$ , and since there is no elements in  $K$  can be expressed as a sum of distinct divisors of  $x$ . We get that x is  $\omega$ -number.

The second part of the prove is to show that  $x$  is PA-number it is enough to show that  $\Delta(c \prod_{i=1}^{s} q_i) < 0$  for all  $s < n$ .

$$
\Delta(cq_1) = \sigma(\prod_{j=1}^r \overline{q}_j)(q_1 + 1) - 2 \prod_{j=1}^r \overline{q}_j q_1
$$

$$
= \left( \prod_{j=1}^r (\overline{q}_j + 1) - 2 \prod_{j=1}^r \overline{q}_j \right) q_1 + \prod_{j=1}^r (\overline{q}_j + 1)
$$

$$
= \Delta \left( \prod_{j=1}^r \overline{q}_j \right) q_1 + \prod_{j=1}^r (\overline{q}_j + 1)
$$

So  $\Delta(cq_1)$  less than zero (deficient), since  $\Delta(c)$  ≤ -1 and  $q_1$  greater than  $\prod_{j=1}^r (\overline{q}_j + 1)$ .

Now, we went to show that  $\Delta(cq_1 ... q_{n-1}) <$ 0 for  $n \geq 3$ . We have

$$
\Delta \left( c \prod_{i=1}^{n-1} q_i \right) = \Delta \left( \frac{c \prod_{i=1}^n q_i}{q_n} \right)
$$
  
=  $\sigma \left( \frac{c \prod_{i=1}^n q_i}{q_n} \right) - 2 \frac{c \prod_{i=1}^n q_i}{q_n}$ 

1

$$
= \frac{\sigma(c \prod_{i=1}^{n} q_i)}{q_n + 1} - 2 \frac{c \prod_{i=1}^{n} q_i}{q_n}
$$

$$
= \frac{\Delta(c \prod_{i=1}^{n} q_i) - 2 \frac{c \prod_{i=1}^{n} q_i}{q_n}}{q_n + 1}
$$

Therefore,  $\Delta(c \prod_{i=1}^{n-1} q_i) < 0$  since for  $\Delta(x) \in \mathcal{K}$ , so  $\Delta(x) < (k+1)q_1 \leq$  $(\ell+1)q_1 < (\frac{q_1}{n})$  $\frac{q_1}{n} + 1)q_1 < q_1^2$ .

And

$$
2\frac{c\prod_{i=1}^{n}q_i}{q_n} = 2c\prod_{i=1}^{n-1}q_i > 2cq_1^2 > q_1^2.
$$

So  $\Delta(c \prod_{i=1}^{n} q_i) < 2c \prod_{i=1}^{n-1} q_i$ . Hence  $c \prod_{i=1}^{s} q_i$ is deficient for all  $s < n$ .

As  $x = c \prod_{i=1}^{n} q_i$  is abundant and by using lemma 4.4, so x is PA-number. Hence x is  $\omega_p$ number.

# **3. Enhancing the bounds of**  $(N_3(x) - \tau x)$

 We will need to recall a fundamental theorem, which will be used in the proof of the main theorem.

# **3.1. Theorem**

For k greater than or equal 1 the  $k$  –prime  $q_k$ satisfies the inequalities

$$
\frac{1}{6}klog k < q_k < 12(k\log k + k\log 12e^{-1}).
$$

**Proof:** for a proof see [6, Theorem 4.7].

 After preparing the necessary concepts, now we are able to prove theorem.

## **3.2. Theorem**

Let  $\{x_n\}_{n=1}^{\infty}$  to be an infinite sequence of a square-free  $\omega_{p}$ -numbers, then

$$
N_3(x_n) - \tau x_n = \Omega(x_n e^{-AG(x_n)}) \qquad \text{for all } A > 1,
$$

Where

$$
G(x_n) = \log x_n \left(\log_3 x_n\right)^{-\frac{1}{2}}.
$$

#### **Proof:**

In previous paper [2], we proved that:

$$
N_3(x) - \tau x = \Omega(xe^{-ck_x})
$$
 for every  $c > 1$ ,

where

$$
k_x = \log x \left(\frac{\log_4 x}{\log_3 x}\right)^{\frac{1}{2}}.
$$

This is valid for any x goes to  $\infty$ . As a special case, let  $\{x_n\}$  to be an infinite sequence of square-free  $\omega_{\text{p}}$ number  $x_n = \prod_{i=1}^k q_i$ , then one can get:

$$
N_{3}(x_{n}) - \tau x_{n} \geq B \prod_{i=1}^{k} q_{i} e^{-c \log \prod_{i=1}^{k} q_{i} \left(\frac{\log_{4} \prod_{i=1}^{k} q_{i}}{\log_{3} \prod_{i=1}^{k} q_{i}}\right)^{\frac{1}{2}}}
$$
\n
$$
\geq B \prod_{i=1}^{k} q_{i} e^{-c \log \prod_{i=1}^{k} q_{i} \left(\frac{\log_{3} \left(\sum_{i=1}^{k} \log q_{i}\right)}{\log_{3} \prod_{i=1}^{k} q_{i}}\right)^{\frac{1}{2}}}
$$
\n
$$
> B \prod_{i=1}^{k} q_{i} e^{-c \log \prod_{i=1}^{k} q_{i} \left(\frac{\log_{3}(k \log q_{k})}{\log_{3} \prod_{i=1}^{k} q_{i}}\right)^{\frac{1}{2}}}
$$
\n
$$
> B \prod_{i=1}^{k} q_{i} e^{-c \log \prod_{i=1}^{k} q_{i} \left(\frac{\log_{3}(kq_{k})}{\log_{3} \prod_{i=1}^{k} q_{i}}\right)^{\frac{1}{2}}}
$$
\n
$$
\geq B \prod_{i=1}^{k} q_{i} e^{-A \log \prod_{i=1}^{k} q_{i} \left(\frac{1}{\log_{3} \prod_{i=1}^{k} q_{i}}\right)^{\frac{1}{2}}}
$$

Since  $kq_k < 12k(k \log k + k \log 12e^{-1})$  by (theorem 2.1.) Therefore,

$$
N_3(x_n) - \tau x_n = \Omega\left(x_n e^{-A \log x_n (\log_3 x_n)^{-\frac{1}{2}}}\right) \text{ for every } A > 1.
$$

## **4. Conclusion**

This work explains how could the form of  $\omega_p$ -numbers effect on the bound of the generalized counting function of integers  $N_3$  and thus restrict the gap between the error terms of Ω-results for  $(N_3 - \tau x)$  and the error terms of O-results for  $(N - \tau x)$  on Riemann Hypothesis. One can use this form to show the effect on O-results for  $(N_3(x) - \tau x)$ .
