Abstract

Background: A question that lies at the very heart of language acquisition research is how children learn semi-regular systems with exceptions (e.g., the English plural rule that yields *cats, dogs*, etc, with exceptions *feet* and *men*). We investigated this question for Hindi ergative *ne* marking; another semi-regular but exception-filled system. Generally, in the past tense, the subject of two-participant transitive verbs (e.g., *Ram broke the cup*) is marked with *ne*, but there are exceptions. How, then, do children learn when *ne* marking is required, when it is optional, and when it is ungrammatical?
Methods: We conducted two studies using (a) acceptability judgment and (b) elicited production methods with children (aged 4-5, 5-6 and 9-10 years) and adults.
Results: All age groups showed effects of *statistical preemption*: the

greater the frequency with which a particular verb appears with versus without *ne* marking on the subject – relative to other verbs – the greater the extent to which participants (a) accepted and (b) produced *ne* over zero-marked subjects. Both children and adults also showed effects of clause-level semantics, showing greater acceptance of *ne* over zero-marked subjects for intentional than unintentional actions. Some evidence of semantic effects at the level of the verb was observed in the elicited production task for children and the judgment task for adults.

Conclusions: participants mainly learn ergative marking on an input-based verb-by-verb basis (i.e., via statistical preemption; verb-level semantics), but are also sensitive to clause-level semantic considerations (i.e., the intentionality of the action). These findings add to a growing body of work which suggests that children learn semi-regular, exception-filled systems using both statistics and semantics.

Plain language summary

Native language speakers of Hindi often produce sentences such as "*Ram ne cup todaa* (Ram broke the cup)". However, not all subjects (i.e., Ram) of verbs in sentences as such receive *ne* marking (e.g., Ram kitab laayaa (Ram brought the book). How, then, do children learn when *ne* marking is required, when it is optional, and when it is ungrammatical? The present study investigated the use of *ne* marking using two tasks: a) asking children (aged 4–5, 5–6 and 9–10 years) and adults to indicate the extent to which sentence they heard was acceptable or unacceptable ("Ram kitab laayaa", "*Ram-ne kitab laayaa"); b) asking children (aged 4–5, 5–6 years) to produce sentences with verbs where the subject may or may not be marked with a *ne* marker. Both children and adults accepted or produced the *ne* marker with the subject of a verb if they frequently heard the subject of the verb associated with the *ne* marker in the input. Further, children and adults accepted the *ne* marker on subjects when the action was intentional versus unintentional. Thus, these findings suggest that children may learn using partial regularities in the language system based on the input they hear and the properties of the action being performed.

Introduction

As anyone who has attempted to learn a new language as an adult will know, languages are full of semi-regular patterns, i.e., rules with exceptions. For example, most English nouns form a plural with *-s* (e.g., *cats*, *dogs* etc.), which makes it difficult for children and second-language learners alike to learn exceptions such as *feet* and *men*. At the sentence level, English speakers can say both *The boy moved* and *Somebody moved the boy*, but not both *The boy danced* and **Somebody danced the boy*; and again, learning these exceptions proves difficult for first- and second-language learners alike (e.g., Bowerman, 1988; Robenalt & Goldberg, 2016).

The question of exactly how learners acquire these exception-filled generalizations has implications not just for language, but for human cognition more generally (e.g., Pinker, 1999). Are our cognitive categories and processes best thought of as formal rules with memorized exceptions, or as fuzzier, more probabilistic generalizations? This debate has some surprisingly broad implications; for example, how best to design self-driving cars (e.g., Marcus & Davis, 2019). Should such cars be hard-wired with formal rules to follow in particular situations, or simply provided with huge amounts of training data and left to form their own probabilistic generalizations?

Unsurprisingly, given its broad linguistic and non-linguistic implications, the question of how to acquire exception-filled generalizations has inspired a great deal of theoretical debate and empirical research. However, with just a handful of exceptions (e.g., Ambridge *et al.*, 2020; Ambridge *et al.*, 2022) research on child language has mainly been restricted to English (e.g., Alishahi & Stevenson, 2008; Ambridge *et al.*, 2008; Ambridge *et al.*, 2009; Ambridge, 2013; Ambridge & Ambridge, 2020; Ambridge & Blything, 2016; Ambridge & Brandt, 2013; Ambridge *et al.*, 2011; Ambridge *et al.*, 2012a; Ambridge *et al.*, 2012b; Ambridge *et al.*, 2013; Ambridge *et al.*, 2014;

Ambridge *et al.*, 2015; Ambridge *et al.*, 2018; Barak *et al.*, 2016; Bidgood *et al.*, 2014; Blything *et al.*, 2014; Boyd & Goldberg, 2011; Brooks & Zizak, 2002; Brooks *et al.*, 1999; Goldberg, 2011; Gropen *et al.*, 1991; Harmon & Kapatsinski, 2017; Hsu & Chater, 2010; Irani, 2009; Li & MacWhinney, 1996; Perek & Goldberg, 2017; Perfors *et al.*, 2010; Robenalt & Goldberg, 2015; Robenalt & Goldberg, 2016; Stefanowitsch, 2008; Theakston, 2004; Twomey *et al.*, 2014; Twomey *et al.*, 2016; Wonnacott *et al.*, 2008), including two book-length treatments (Goldberg, 2019; Pinker, 1989).

This focus on English is unfortunate given that most – and quite possibly all – languages exhibit this phenomenon of generalizations with exceptions somewhere in the system. Our goal in the present study is therefore to investigate this problem in a domain i.e., ergative marking in Hindi. The phenomenon is that, for active (i.e., not passive) sentences in the past tense/perfective aspect (i.e., denoting a completed action, but see Singh, 1998), the subject of two-participant transitive sentences (1) – but not single-participant intransitive sentences (2) – is *typically* marked by the clitic marker *ne* [1]

(1) *Raam=**ne** gilaas=ko toR-aa*

Ram=Erg glass=Acc break-Msc.Sg.Prf

Ram broke the glass.

(2) *Raam-0 hãs-aa*

Ram-Nom laugh-Msc.Sg.Prf

Ram laughed.

However, some sentences that meet all of the other criteria (i.e., active, past tense/perfective aspect, transitive) still do not show *ne* marking (3); indeed, most native-speaking adults would regard such marking as ungrammatical (4).

(3) *laRkaa-0 raakshas=se Dar-aa*

boy-Nom demon=Inst fear-Msc.Sg.Prf

The boy feared the demon.

(4) **laRke=**ne** raakshas=se Dar-aa*

boy=Erg demon=Inst fear-Msc.Sg.Prf

The boy feared the demon.

Complicating the picture still further, in some cases *ne* marking seems to be optional, in that adult native speakers accept both the version with *ne* (5) and without *ne* (6).

(5) *Raam=**ne** samaachaar bolaa*

---

[1] Also, the verb agrees with the highest null-marked argument in the clause and if all arguments receive overt case, the verb exhibits masculine singular default agreement Mohanan (1994) in order to maintain uniformity in verb agreement, the present study used masculine singular nouns for the subject and masculine nouns for the object arguments of transitive verbs.

    Ram told the news.

Although previous naturalistic and experimental studies of Hindi children's ergative marking have been conducted (e.g., Narasimhan, 2005; Pareek *et al.*, 2016) both focussed on errors of omission, rather than the question of how children learn *exceptions* to general patterns of ergative marking; the key question from a learnability perspective.

How, then, do children learn this partial regularity? The previous studies discussed above (mainly focussing on English) have provided evidence for two complementary possibilities. Under the first – statistical preemption (e.g., Goldberg, 1995; Goldberg, 2006; Goldberg, 2011; Goldberg, 2019) – children are sensitive to the probabilistic competition between forms with the same meaning. For example, the overgeneralized forms *foots* and *mans* are outcompeted by repeatedly hearing *feet* and *men*, while the overgeneralized form *[A] danced [B]* (e.g., **Somebody danced the boy*) is outcompeted by repeatedly hearing *[A] made [B] dance* (e.g., *Somebody made the boy dance*). When applied to Hindi ergative marking, preemption holds that via repeatedly hearing (active, past tense/perfective aspect, transitive) sentences containing a particular verb but without *ne* marking (example 3), these "zero-marked" subjects come to outcompete *ne* marked subjects for that verb (example 4). Thus the predictions that we test in the present study are that the greater the frequency with which a particular verb appears with versus without *ne* marking on the subject – relative to other verbs – the greater the extent to which (a) -*ne* marked forms will be preferred over zero-marked forms in a judgment task (Study 1) and (b) -*ne* marked forms will be produced over zero-marked forms in an elicited production task (Study 2).

The second possibility – again supported by previous studies of English and a handful of other languages (e.g., Ambridge *et al.*, 2020; Ambridge *et al.*, 2022; Gropen *et al.*, 1989; Gropen *et al.*, 1991) – is that children might be guided by semantics. For example, at least part of the reason that English speakers prefer *Somebody made the boy dance* over **Somebody danced the boy* is that "dancing" is not really an action that is amenable to outside causation: someone can *ask* a boy to dance, but not force him, he retains some agency. In contrast, English speakers accept both *Somebody made the water boil* and *Somebody boiled the water* because this type of direct, outside causation is possible (Ambridge *et al.*, 2020; Ambridge *et al.*, 2022; Pinker, 1989; Shibatani & Pardeshi, 2002). In the domain of Hindi ergative *ne* marking, effects of semantics might be observed at either or both of two levels: the verb (lexical) and the clause (clausal). At the lexical level, linguistic analyses of Hindi suggest that the higher a verb on a cline of semantic transitivity based on the type of action it denotes, the greater the likelihood that it triggers ergative *ne* marking on the

subjects (e.g., *break, squash, eat > fear, escape, find*; Hopper & Thompson, 1980; Mohanan, 1994; Montaut, 2013). Intentionality (or volitionality) at the clausal level can also contribute to higher transitivity (Hopper & Thompson, 1980): events can be presented as intentional versus unintentional by the use of adverbs that modify the action denoted by the verb (7).

*(7)   Mohan=**ne** rassii-0 khiinc-ii galtii se.*

    Mohan=Erg rope-Nom pull-Fem.Sg.Prf mistake by.

    'Mohan pulled the rope by mistake'

On the other hand, verbs that are lower on the transitivity cline mark subject arguments with non-canonical case-marking (Montaut, 2013). For example, two-participant verbs that denote states (versus actions) typically have subject arguments that are low in agency (e.g., experiencers, recipients, possessors) and object arguments that are not highly affected. In such cases, subjects receive cases such as dative, locative, or genitive (Mohanan, 1994; Montaut, 2013).

(8)   Mohan=ko kitaab-0 caahiye

    Mohan=Dat book-Nom want/need

    'Mohan wants/needs a book.

(9)   niinaa=mE apnii mausii=keliye baRii mamtaa-0 hae.

    Nina=Loc self aunt=for much affection-Nom be.3.Sg. Pres

    'Nina has a lot of affection for her aunt.' (Mohanan, 1994:181)

In terms of the retreat from overgeneralization, then, the verb-level semantics hypothesis holds that children set up a semantically-restricted generalization: that only verbs that are high on this cline of transitivity trigger ergative *ne-* marking (in otherwise suitable contexts).

In the present study, we operationalize this notion of transitivity in verb-level semantics in terms of the degree to which the patient is affected by the action denoted by the verb (Hopper & Thompson, 1980). We ask adult participants to rate sentences describing various actions for "the extent to which the [THING] gets affected or changed by the event in some way". The prediction of a verb-level semantics account is that the higher the rated transitivity, the greater the extent to which *ne* versus zero-marked subjects of the verb, as depicted by the corresponding action in the videos, will be judged as acceptable (Study 1) and produced (Study 2).

However, it is far from clear that a verb-level semantics effect exists for Hindi. Indeed, although ergative case-marking is *predominantly* found with two-participant verbs, it can also optionally occur on the single argument of a small set of intransitive verbs (e.g., *chiikh* 'scream'), apparently marking a volitional action (e.g., Butt & King, 1991; Butt & King, 2003; de Hoop & Narasimhan, 2005; Mohanan, 1994). This raises the possibility that semantic effects on Hindi ergative *ne* marking,

if they exist at all, may occur not at the verb level, but at the clausal level: whether the action denoted by a verb is presented as intentional or unintentional. In terms of the retreat from overgeneralization, then, the clausal-level semantics hypothesis holds that children set up a semantically-restricted generalization: that only actions that are clearly intentional trigger ergative *ne*-marking (in otherwise suitable contexts). In terms of the present study then, the prediction is that presenting an action as intentional rather than unintentional will increase the extent to which *ne* marked forms are – relative to zero-marked forms –rated as acceptable. Note that since none of the theoretical proposals tested make any claims regarding effects of participant sex and/or gender, this information was not recorded.

Study 1: Grammatical acceptability judgments

The sample size, methods and data-analysis plan were registered on the Open Science Framework prior to data collection (Rosenthal, 1979).

Participants

For the grammaticality judgment task, 48 participants from each of three age groups, 5;6–6;6 (*M*: 5.90, *SD*: 0.30), 9;6–10;6 (*M*: 10.06, *SD*: 0.33)[2] and adults (*M*: 22.01, *SD*: 2.60), took part in the study. A further 20 adult speakers completed the semantic ratings task (*M*: 29.81, *SD*: 9.15). These sample sizes were chosen based on similar research conducted previously (Ambridge *et al*., 2020) and because of time and financial constraints (as specified on the relevant grant application). For recruitment, eight schools and two universities were approached in Jabalpur, Bhopal and Delhi in India. Five schools and both the universities agreed to take part in the main study. In total, including online data – see below – data was collected from 100 children aged 9;6–10;6 and 5;6–6;6 (9;6–10;6: 48 data points used, 2 excluded (incorrect lists was administered for one and one child withdrew; 5:6–6;6: 48 data points used, 2 excluded (due to collecting more than our preregistered total)) and 73 adults (Grammatical judgment task: 48 data points used, 4 excluded (4 data points were not saved due to technical issues; Semantics ratings study: 20 data points used, 1 excluded (participant withdrew)).

COVID-19 pandemic restrictions came into force (GOV.UK, 2022; UK Parliament, 2021) before face-to-face testing could be completed and therefore, some participants were recruited via the online recruitment portals Prolific and Amazon Mechanical Turk: For the judgment task, data for all 48 adults and 45/48 children aged 9;6–10;6 were collected in face-to-face sessions. Data from 3/48 children aged 9;6–10;6 and 48/48 children aged 5;6–6;6 were collected in online sessions. All the data for the adult semantics ratings task (20/20 participants) were collected in online sessions. As part of a pilot study to refine the tasks, ten adults completed the grammaticality judgment task and two adults completed the semantics rating

task (all face-to-face). These data are not included in the main analyses.

Children and adults with Hindi as their first language and no known history of speech and language impairments were eligible to take part in the study. All participants had Hindi as their first language and knew one or more additional language. No monetary incentives were provided to schools, though children received stickers and pencils as rewards when data were collected in face-to-face sessions. Parents/caregivers who assisted their children during online data collection received £5 (Indian Rupee equivalent) as compensation for their time and effort. For the grammaticality judgment and the semantic ratings tasks, adult participants received 200 INR and £7.50 GBP compensation respectively.

Materials

Verbs. Forty action verbs were chosen from the Action/Process category of Concepticon (List *et al*., 2016), a database of concepts that are commonly lexicalized as words across languages (e.g., *run, jump, dance*) and two published sources on Hindi: Piepers (2016) and Mohanan (1994). Eligible verbs had to be (a) transitive verbs that took an ergative or nominative subject (b) familiar to young children, and (c) easily depictable in animations. In total, according to the intuitions of two native speakers of Hindi, of the 40 verbs, 25 verbs occur with the ergative *ne* marker on the subject, 5 verbs occur with zero-marking and 10 verbs exhibited optional *ne* marking (versus zero-marking).

Sentences. For each verb, four sentence structures were generated which were manipulated for the (a) presence or absence of the ergative *ne* marker on the subject (7a & 7b), and (b) indicating intentionality of the agent performing the action (7a and 7b show the more intentional situations, 7c & 7d the less intentional situations by use of an adverbial phrase *galtii se*). All sentences were in the form of [AGENT] [PATIENT] [VERB], where the agent was always *The boy* and the patient an inanimate[3] masculine noun (to ensure uniform verb agreement marking: masculine, singular perfective).

---

[2] The age data for 2 children were missing because of technical faults, so the mean age was calculated from the data obtained for 46 children.

[3] There was one exception, i.e. for the verb 'fear from', we used an animate noun ('demon') as the patient.

7d. *laRkaa-0 galtii=se khel-0 jiit-aa*

The boy-Nom mistake=Inst game-Nom win-Msc.Sg.Prf

The boy won the game by mistake

Animations. The animations were created using Moho Debut 12. This is proprietary software, and no free alternative is available. However, a free trial version is available, and the animations themselves are encoded as mp4 files, which can be viewed using a wide range of free software packages.

For each verb, two different animations were created, one depicting the intentional and the other the unintentional event (all performed by the same boy character). For the animations, see *Underlying data* (Ambridge *et al*., 2023a).

For the grammaticality judgment task (Study 1), the animations were accompanied by the relevant sentence structure as described above. The sentences were recorded by a male Hindi speaker using the freeware package Audacity 2.1.2 (Audacity Team, 2016). Seven different animations were used in the practice trials of the grammaticality judgment task (Ambridge *et al*., 2023a).

Procedure

Grammaticality judgment task. The face-to-face grammaticality judgment task was administered in line with the procedure outlined in Ambridge *et al*. (2008: 105–107), using the free Open Source platform PsychoPy2 (Peirce *et al.,* 2019). In brief, the participant played a game with a talking dog (who produces the sentences via a loudspeaker) and were asked to assist the dog in "learning Hindi". On each trial the participant and the talking dog watched a video together and the dog provided a description of the action. The participant gave feedback to the dog on the acceptability of the sentence produced (grammatical/ungrammatical) by selecting either a red counter (to indicate ungrammatical) or a green counter (to indicate grammatical), then placing this counter on a five-point smiley face scale ranging from sad (red) to happy (green) to indicate the degree of (un)grammaticality. Due to the COVID-19 pandemic, part of the data (48 children aged 5;6–6;6 & 3 children aged 9;6–10;6) was collected online using Gorilla, a platform where experiments can be built for free and fees are paid for data collection. There is no free alternative. For the online version, parents/caregivers were asked to assist the child in understanding the task, completing the practice trials, and inputting children's answers. However, they were asked to refrain from prompting or assisting their children when completing the main trials.

For adults (*N*=48), the design was completely within subjects. For each of 40 verbs, adults rated the grammatical acceptability of four sentences (and the accompanying videos), crossing ergative subject marking (with *ne*/without *ne*) and intentionality (intentional/unintentional), for a total of 160 trials in one session which took approximately 30 minutes to complete (see examples 7a–d).

As children would have found it difficult to complete 160 trials, a reduced set of 20 verbs (5 obligatory *ne* verbs, 5 obligatory

zero marked verbs, and 10 optional verbs, according to the intuition of two native-speakers) was chosen from the larger set of 40. Since even 80 trials (20 verbs x 4 sentence types) would have been too many for young children, two counterbalance lists - each containing 15 verbs were created. The 10 verbs for which *ne* marking is somewhat "optional" (*know, leap-over, lose, find, talk nonsense, sing, smell, speak, understand* and *win*) were included in both lists because they are the verbs that are most likely to show sensitivity to our preemption and semantics predictors, as well as the intentionality manipulation. The 10 verbs which occur with *ne* or zero marking (according to native speaker intuitions) were considered to be less sensitive to the experimental manipulations, so were split across the two lists. i.e., List 1 comprised 2 obligatory verbs and 3 zero verbs (as well as the 10 optional verbs); list 2 comprised 3 obligatory verbs and 2 zero verbs (as well as the 10 optional verbs). Thus, each child provided ratings for all four sentence structures for 15 verbs (60 trials in total). For the full verb lists, see Underlying data (Ambridge *et al*., 2023a). Children completed the trials over two sessions which took place either on the same day after a break or on two separate days.

Trials were presented in a random order. Prior to the main task, all participants completed a training session during which they received feedback for seven sentences with varying degrees of acceptability (which were Hindi translations of the sentences used in a study with English-acquiring children in Ambridge *et al*., 2008).

Semantic ratings task. As mentioned in the pre-registration, for the semantic ratings task, participants viewed all 80 animations (the same animations as in the judgment task; both intentional and unintentional) along with the corresponding verb and the patient argument that could be used to describe the action and provided ratings for patient affectedness. However, the results that we obtained did not seem, based on our native intuitions, to really capture the relevant notion of affectedness and hence a revised, simplified version of the task was used instead. The modified semantic ratings task (*N*=20, adults only) was also completely within-subjects. Participants were given 40 sentences in the passive form describing an action (e.g. "*The potato was cooked*") and rated the extent to which the object was affected or changed in the action, according to the following instructions (translated into Hindi). They did not view animations along with the sentences.

Thanks for taking part in this experiment.

In total, you will see 40 sentences.

Each sentence will describe an action that has been carried out.

Please rate the extent to which the [THING] gets affected or changed by the event in some way.

Participants were asked to provide their ratings using a visual analogue scale which ranged from

Not at all---Very much so

Prior to the main trials, participants completed three practice trials. The materials for the main and practice trials can be accessed on the OSF project link in the folder titled 'Ergative_SemanticsTaskMaterials'.

Predictors

Preemption. The prediction that follows from preemption is that the greater the frequency with which a particular verb appears with versus without *ne* marking on the subject – relative to other verbs in the test set – the greater the extent to which *ne* marked forms will be preferred over zero-marked forms in the judgment task. As in previous studies (Ambridge *et al.*, 2018; Ambridge *et al.*, 2020) we operationalized this measure using a scaled and centred chi-square statistic which measures how often, in past tense/perfective aspect active sentences, a particular verb triggers ergative case marking as compared with all other verbs in the test set of 40, e.g., (example figures only):

	Subject with *ne*	Subject without *ne*
Target verb	2	10
All other verbs	10,000	1,500

The frequency counts were obtained from the Hindi monolingual corpus, Indic NLP Suite: Monolingual Corpora (Kakwani *et al.*, 2020) which consists of 1 million sentences. The corpus was parsed using the Hindi parser (Bhat *et al.*, 2017) and the counts for subjects marked with the *ne* ergative and zero markers were extracted. The chi-square method for calculating the preemption predictor was exactly the same as in Ambridge *et al.* (2018).

Semantics. Verb and clause-level semantics were measured using patient affectedness ratings and the intentionality manipulation respectively. To create the patient affectedness predictor for each verb, we took the mean rating (on the 100-point visual-analogue scale) on the semantics ratings task described above across all 20 participants, then scaled and centred the mean ratings. The binary intentionality manipulation was instantiated by having participants rate intentional and unintentional versions of the sentences (see examples 7a–d) on the judgment task. We did not investigate the effect of intentionality on the *production* of *ne* marking (the subsequent Study 2) since children might not be able to infer the intentionality of an action from the animations alone (recall that in the judgment task, the relevant sentences included the term "unintentionally", see examples 7a–d). It is important to also emphasize that the intentional and unintentional versions of each sentence were paired with different videos. For example, the intentional version of *The boy soaked the cloth* was illustrated by the boy dipping the cloth into water, while the unintentional version was illustrated by a girl knocking the boy, forcing him to unintentionally drop the cloth into water.

Statistical analyses

The data were analysed using R version 3.6.3 (R Studio Version 1.2.5042) (R Core Team, 2020). Mixed effects models were run using the lme4 package (Bates *et al.*, 2015); *p* values were obtained using lmerTest (Kuznetsova *et al.*, 2017). Statistical analyses were conducted for each age group separately (5;6–6;6; 9;6–10;6; Adults). We did not compare directly across groups since the tasks are not strictly comparable for the adults and children who completed different verb sets.

All analyses were conducted according to our pre-registered analysis plan[4]. Two aspects of this plan are particularly important to highlight. First, the main set of analysis uses *difference scores*: preference for the *ne* over zero marked form of the subject argument of each verb, within each intentionality pair, within each participant. These scores control for general (dis-)preferences that participants may show for particular verbs and/or videos. However, for the sake of completeness, we also report analyses conducted on the raw *ne* and zero-marked forms. Second, we report both (a) simultaneous models, in which the preemption, verb-level semantics (patient affectedness) and clause-level semantics (intentionality) are all included and (b) single-predictor models, each of which includes only preemption OR verb-level semantics (along with intentionality). This is necessary because we expected a high degree of collinearity between these predictors: Indeed, a by-verb correlation analysis revealed moderate correlations between the verb-semantics and preemption predictors: r=.40 for the child set, and r=.26 for the larger adult set.

Results

Table 1–Table 9 show, for each age-group, the simultaneous and single-predictor models for (Table 1–Table 3) Difference scores, (Table 4–Table 6) raw *ne* marked forms and (Table 7–Table 9) raw zero-marked forms. The ratings are plotted in Figure 1–Figure 4.

Children aged 5;6–6;6

Focussing first on the most informative difference-score analyses (Table 1), the main effect of **Preemption** ($p < .01$) was significant in both the simultaneous and single-predictor models. **Intentionality** (clause-level semantics) was a significant predictor in the simultaneous -predictor model ($p = 0.03$) though not the single-predictor models ($p=0.06$ in both cases; though this would not seem to be a meaningful difference, since the estimate is the same, and the *p* values straddle the 0.05 boundary). This significant effect of Preemption was also observed for raw *ne* marked sentences ($p < .05$), again in both the simultaneous and single-predictor models, but not for zero-marked sentences. Main effects of Intentionality (clause-level semantics) were also observed for raw ratings of *ne* (as expected) and zero-marked sentences. This latter finding is unexpected, but may reflect a general preference for intentional actions and the unintentional actions being less typical. In summary, the 5–6 year-olds showed clear evidence of Preemption and Intentionality.

---

[4] In fact, the model syntax in the preregistration contained a typo such that the Verb-semantics*Intentionality interaction was not included, although it is clear from the main text of the pre-registration that it was intended to be. Thus the model did include this analysis.

Figure 1. Relationship between Preemption counts and Difference scores across clause-level-semantics conditions and age groups. Figure 1 shows the relationship between preemption counts (higher corpus relative verb frequency triggering ne form) and difference scores across clause-level-semantics conditions (Intentional=Deliberate, Unintentional=Accidental) and age groups (5;6–6;6. 9;6–10;6, Adults).
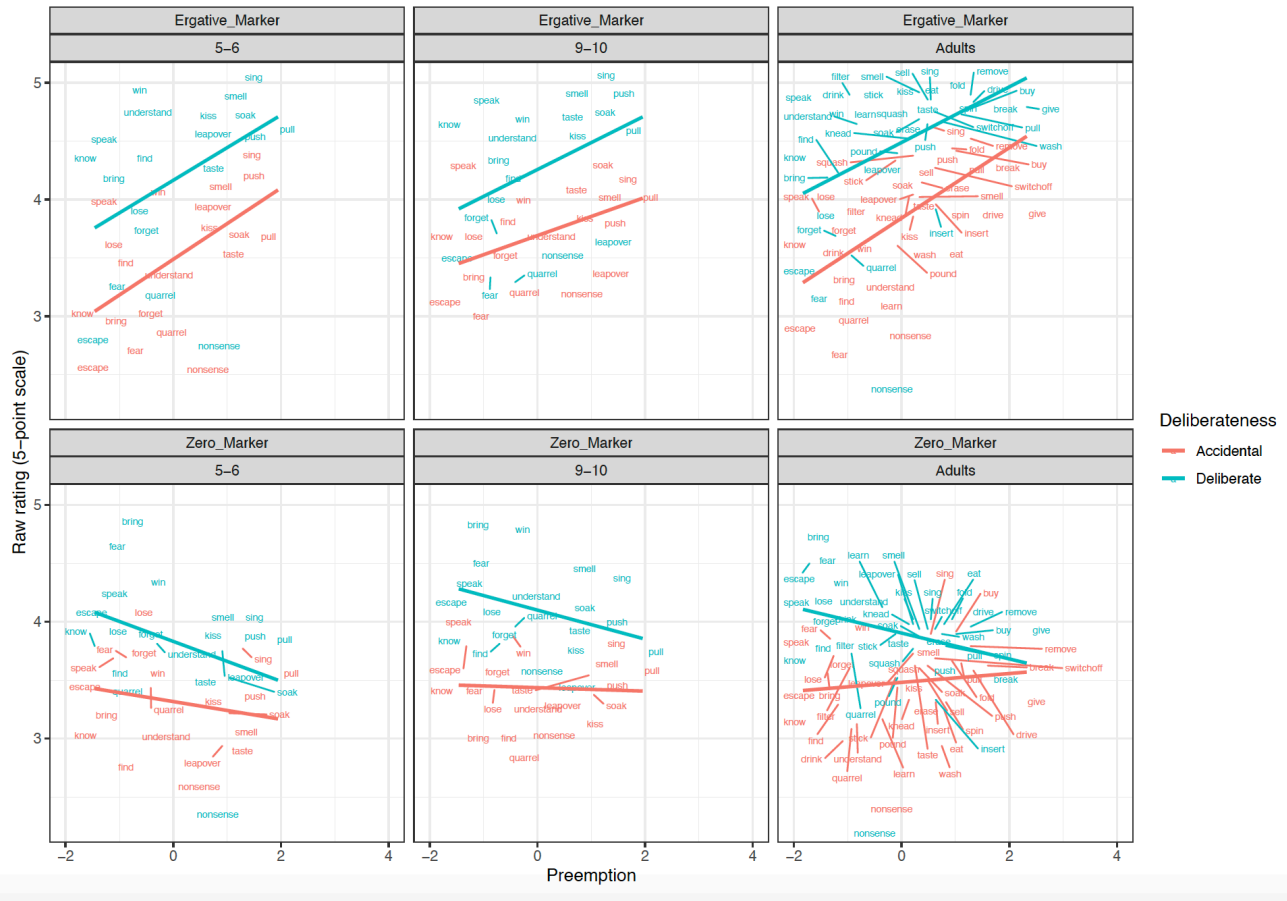

Figure 2. Relationship between Preemption counts and Raw scores across clause-level-semantics conditions and age groups.
Figure 2 shows the relationship between preemption (higher corpus relative verb frequency triggering ne form) counts and raw scores across clause-level-semantics conditions (Intentional=Deliberate, Unintentional=Accidental) and age groups (5;6–6;6. 9;6–10;6, Adults).

Children aged 9;6–10;6

Although no significant main effects of predictors or interactions were observed for difference-scores (Table 2), the older children did show the predicted **Intentionality** (clause-level semantics) effect for the raw *ne* marked sentences, in both the single-predictor and simultaneous models. The Preemption effect was nearing significance in the single-predictor model for raw *ne* marked sentences ($p < .06$). For zero-marked sentences, only a relatively-uninformative main effect of Intentionality was observed (again, presumably reflecting a general preference). In summary, the 5–6 year-olds showed clear evidence of Intentionality though – surprisingly – not preemption.

Adults

Focussing again on the most-informative difference-score analyses (Table 3), main effects of Intentionality ($p < .01$) and Preemption ($p < .01$) were significant in both the simultaneous and single-predictor models. Unlike for children,

a narrowly significant effect of verb-level semantics (i.e., patient-affectedness) was observed ($p = 0.03$), but only in the single-predictor model (though it would have been more comfortably significant if we had pre-registered a one-tailed directional statistical test alongside our directional prediction). The effects of Intentionality (clause-level semantics) and Preemption – but not verb-level semantics – were also observed (again for both simultaneous and single-predictor models) for *ne* marked sentences (p *values* $< .01$). For zero-marked sentences, the only significant effects that were observed were unexpected and difficult-to-interpret: a main effect of Intentionality and an interaction of Intentionality x Preemption. In summary, the adults showed clear evidence of Preemption and Intentionality.

Study 1 (grammatical acceptability judgments): summary

Although the fine-grained pattern of results is rather complicated, overall, a clear picture emerges: All age groups showed
Figure 3. Relationship between verb-level Semantics and Difference scores across clause-level-semantics conditions and age groups. Figure 3 shows the relationship between verb-level semantics (Patient-affectedness ratings) and difference scores across clause-level-semantics conditions (Intentional=Deliberate, Unintentional=Accidental) and age groups (5;6–6;6. 9;6–10;6, Adults).

clear effects of Intentionality (clause-level semantics) and – apart from the middle age group – Preemption (though this likely reflects a chance finding, rather than genuine U-shaped learning). That is, ergative *ne* marking is preferred when (a) relative to other verbs, the relevant verb is more likely to occur with *ne* than zero-marking in the input and (b) the event is intentional, rather than unintentional. Both of these factors therefore seem to play a key role in learning.

Much more limited evidence was obtained for the effect of verb-level semantics (i.e., patient-affectedness, as determined by the semantic ratings task). However, the fact that such an effect was observed for adults – though only for the single-predictor difference-score model – suggests that, while this factor may play little-to-no role in acquisition *per se* – it may have historically determined which verbs come to prefer *ne* versus zero subject marking.

A potential concern surrounding these conclusions, though, is that they are based entirely on acceptability judgment data,

which can be noisy with young children and – even more crucially – may not be directly reflective of the linguistic mechanisms that they use when producing speech (including errors of ergative *ne* marking). We therefore investigated the potential effects of preemption and verb-level semantics in a production study. As discussed earlier, this second study did not investigate intentionality since (a) we were not confident that children could reliably determine intentionality from the animations and (b) we already have clear evidence of a role for intentionality – for all age-groups – from Study 1.

Study 2: Elicited production
The sample size, methods and data-analysis plan were registered prior to data collection. For the preregistration document, please see *Extended Data* (Ambridge *et al.*, 2023b).

Participants
48 children were recruited in each age group, 4;0–5;0 (*M*: 4.70, SD: 0.34) and 5;6–6;6 (*M*: 6.00, *SD*: 0.32) years, for the elicited production task. Recruitment methods (four schools were
Figure 4. Relationship between verb-level Semantics and Raw scores across clause-level-semantics conditions and age groups.
Figure 4 shows the relationship between verb-level semantics (Patient-affectedness ratings) and raw scores across clause-level-semantics conditions (Intentional=Deliberate, Unintentional=Accidental) and age groups (5;6–6;6. 9;6–10;6, Adults).

approached and all agreed to take part in the study) and ethical approval were same as Study 1. Parents who supervised their children in completing the task received 500INR compensation for their time. We ran a pilot study with seven children aged 4–5 in order to ascertain the feasibility of running an elicited-production task with this age group. These data are not included in the analyses presented below.

Materials
For the elicited production task, the same list of 40 verbs and animations developed in Study 1 were used. Children watched the animations from the intentional condition only. The animations were accompanied by a "clue word": the relevant inflected verb form in the simple past tense in both audio and written formats. The verb forms were recorded by a female near-native Hindi speaker on Audacity 2.1.2 (Audacity Team, 2016). Seven different animations, depicting the actions corresponding to Hindi verbs *jalaana (burn)*, *kaaTnaa (cut)*, *nach-aana (dance)*, *(sajaanaa) decorate, (giraanaa) drop, (sukhaana)*

dry, and *khiilaana (feed)* were used for the practice trials, which depicted an action involving a boy or an inanimate object.

Procedure
The experiment ran on the Gorilla platform and children completed the task over Zoom along with a parent or guardian. The experimenter was present during the Zoom session in order to answer any questions that the parents might have when supervising their child but did not conduct the experiment, which was entirely computerized. The task was set up as a game wherein the child watched a video depicting the action denoted by each verb and built a sentence describing the action using the clue word (the verb corresponding to the depicted action, inflected for past tense/perfective inflection) provided by a talking dog. The video was presented first followed by the clue word, and the child's responses audio-recorded. The parent or the guardian was asked to assist the child in audio-recording their responses on the computer, but not to provide any hints regarding the form of the responses themselves. The child

was instructed in Hindi on how to complete the task. For the detailed instructions for the task, translated into English, see *Extended data* (Ambridge *et al.*, 2023b).

All children saw the same list of 40 verbs. The order of presentation of the verbs was fully randomised for each child, using the randomisation function of the Gorilla platform. Each child completed the experiment in a single session which took approximately 30–40 minutes per child. All children completed seven practice trials prior to the main task. In the practice trials, children described the event and received feedback on their responses. The feedback consisted of a correct description of the event which the parent read out to the child.

Predictors

The frequency counts (chi-square measure) and patient-affectedness ratings obtained in Study 1 served as the preemption and verb-level semantics predictors for Study 2. For this production study, the preemption account predicts that the higher the (scaled and centred) chi-square value (such that positive and negative values represent a bias towards the *ne* marked and zero marked subjects respectively), the greater the probability of children using the ergative *ne* versus zero marking on the subject (with all other responses discarded as missing data). The verb-level semantics account predicts that the higher the (scaled and centred) patient-affectedness score, the greater the probability of children using the ergative *ne* versus zero marking on the subject.

Statistical analyses

The data were analysed using R version 3.6.3 (R Studio Version 1.2.5042) (R Core Team, 2020). All analyses were conducted exactly according to our pre-registered analysis plan which is reproduced below. The preregistered analysis plan was as follows:

> The above mentioned hypotheses will be tested in three ways. First, we will run a maximal (as far as will converge) mixed effects model (using lme4 in R) investigating the verb semantics predictor (Hypothesis 2) only - since this is the primary predictor of interest. P values will be calculated via the "drop1" method. Second, we will run a maximal (as far as will converge) mixed effects model (using lme4 in R) investigating the preemption predictor (Hypothesis 1) only. P values will be calculated via the "drop1" method. Third, we will run a maximal (as far as will converge) mixed effects model (using lme4 in R) investigating both the verb semantics and the preemption predictors. P values will be calculated via the "drop1" method (see attached syntax). This is considered a secondary analysis due to likely collinearity between the predictors.

Mixed effects models were run using the lme4 package (Bates *et al.*, 2015); *p* values were obtained using the 'drop1' method (i.e., nested models were compared using the likelihood ratio test). Statistical analyses were conducted for each age

group separately (4;00–5;00; 5;6–6;6). As in Study 1, we ran both simultaneous and single-predictor models.

Results

For both age groups, main effects of preemption were significant in both the simultaneous and single-predictor models (see Table 10). As expected, the higher the (Z-score standardized) chi-square value operationalizing preemption, the greater the children's production probability of using the ergative marker *ne* on the subject versus zero marking (see Figure 5). Significant effects of Verb Semantics (as measured using the patient affectedness measure) were observed in single-predictor models, but not in the simultaneous models, for both the age groups (see Table 10 & Figure 6). What this suggests is that effects of both preemption and verb semantics are present in the data – and, indeed show broadly similar effect sizes – but that we cannot pick them apart as they are inevitably highly correlated: Verbs that are high in transitivity (Verb level semantics) tend to occur frequently with ergative *ne-* marking in the input (preemption). That said, across both studies, preemption seems to be larger and more robust effect.

Discussion (Study 2)

In summary, the results of Study 2 (elicited production) echo those of Study 1 (acceptability judgments) in relation to the effects of preemption which were observed in every analysis. Unlike in Study 1, however, effects of verb level semantics were also observed; though these cannot statistically be teased apart from preemption. Taken together, then Study 1 (acceptability judgments) and Study 2 (elicited production) suggest that statistical preemption is the main mechanism by which children learn which verbs do and do not trigger ergative *ne* marking. However, evidence from Study 1 suggests that clause-level semantics (in the form of intentionality) also influences judgments about the acceptability of ergative *ne* marking. The role of verb-level semantics is less clear: such effects were observed only for adults in Study 1, and only in the single-predictor models for Study 2. Thus, it seems that effects of Verb-level semantics are present in the data, but we cannot tell whether they are actually utilized by children in learning, or have merely historically determined which verbs tend to occur with and without ne- marking in the first place.

General discussion

A question that lies at the very heart of language acquisition research is how children learn generalizations with exceptions (e.g., the English plural rule that yields *cats, dogs*, etc, with exceptions *feet* and *men*). Previous research has provided evidence for two accounts. Statistical preemption (e.g., Goldberg, 1995; Goldberg, 2006; Goldberg, 2011; Goldberg, 2019) holds that children are sensitive to the competition between forms with the same (or similar) meanings. For example, in the domain of verb argument structure, repeatedly hearing *[A] made [B] dance* (e.g., *Somebody made the boy dance*) probabilistically outcompetes – that is, statistically pre-empts – *[A] danced [B]* (e.g., **Somebody danced the boy*). Semantic accounts hold that learners are guided in part by meaning. For example, the reason we can say *Somebody boiled the water* but not *Somebody*

Table 10. Elicited Production Responses: Simultaneous and Single-predictor Models for Both Age Groups.

Figure 6. Relationship between verb-level Semantics and Elicited Production across Age groups. Figure 6 shows the relationship between verb-level semantics (Patient Affectedness) and elicited production across age groups (4–5, 5;6–6;6).

danced the boy is that "boiling" but not "dancing" is an activity that an external causer can more-or-less force another entity to undergo (Ambridge *et al.*, 2020; Ambridge *et al.*, 2022; Pinker, 1989; Shibatani & Pardeshi, 2002).

The present study tested the preemption and semantics hypotheses for Hindi ergative *ne* marking: another semi-regular system characterized by exceptions. The preemption account predicts that the greater the frequency with which a particular verb appears with versus without *ne* marking on the subject – relative to other verbs – the greater the extent to which child and adult participants will (Study 1) accept and (Study 2) produce *ne* over zero-marked subjects. The semantics hypothesis was tested at both the verb and the clause level: At the verb level, this account predicts that the greater the verb's semantic transitivity (as determined in a separate semantic-rating task of patient affectedness) the greater the extent to which child and adult participants will (Study 1) accept and (Study 2) produce *ne* over zero-marked subjects. At the clause level, this account predicts that when an action is portrayed as intentional rather than unintentional, child and adult participants will

show a greater preference (Study 1) for *ne* over zero-marked subjects.

Overall, the findings from the acceptability-judgment study (with 5–6 year-olds, 9–10 year-olds and adults) and the production study (with 4–5 and 5–6 year olds) yield a clear picture. Findings of statistical preemption were observed across the board, suggesting that the main way Hindi-speaking children learn which verbs do and do not trigger *ne* marking is probabilistic input-based learning at the verb level. At the same time, the acceptability-judgment study shows that learners also seem to be sensitive to a clause-level semantic constraint such that intentional actions require *ne* marking to a greater extent than unintentional ones. Effects of verb-level semantics, however, were observed only sporadically, primarily in the adult acceptability judgment data and elicited production data from children. These findings indicate that to some extent, *ne* marking is associated with higher transitivity actions, but this effect disappears when controlling for preemption. Most likely then, transitivity (verb-level semantics) determines which verbs prefer *ne*- versus zero marking historically, but learners primarily

learn these patterns statistically on a verb-by-verb basis (i.e., via statistical preemption).

These results therefore add to a growing body of work which suggests that learners acquire exception-filled generalizations by (a) learning probabilistically from the input which surface form is used by adult speakers to convey a particular meaning (i.e., via statistical preemption) and (b) forming overarching generalizations based on semantics, which allow them to generalize to new scenarios. For Hindi ergative *ne* marking, these semantic effects seem mainly to operate at the level of the clause, specifically reflecting intentionality. That is, in terms of avoiding overgeneralizations, children learn that the exceptions to ergative *ne-* marking occur in contexts with low levels of intentionality. The role of verb-level semantic effects warrants further investigation. Future studies investigating other language systems characterized by partial productivity should therefore take seriously, and investigate empirically, the possibility that effects of semantics exist. In the meantime, the present findings have demonstrated that, for a previously understudied phenomenon – ergative *ne-* marking – learners acquire exception-filled generalizations using both verb-by-verb learning (i.e., statistical preemption) and forming overarching semantic generalizations (here, intentionality).

Ethics and consent

The study was approved by ethics committees at the University of Liverpool, UK (RETH001041) and International Institute of Information Technology – Hyderabad, India (IIITH-IRB-PRO-2021-02). Written informed consent was obtained using online and physical consent forms, depending on whether the task was completed face-to-face or online. For children, written informed consent was obtained from parents. Children provided verbal assent.

Data availability
Underlying data
OSF: Ergative marking in Hindi: Stimuli, data and R code

https://doi.org/10.17605/OSF.IO/7KS63 (Ambridge *et al*., 2023a).

This project contains the following underlying data:
- File name.pdf/xlsx/mp4 (brief description of file (in a few words))

- ErgativeStudy_Animations.zip (contains animations for the grammatical judgment and elicited production tasks in intentional (e.g., BREAK.mp4) and unintentional (e.g., BREAK_A.mp4) conditions; only animations in the intentional condition were used for the elicited production task)

- Ergative_Judgment_SentencesAudio.zip (contains audio files that accompanied the animations in the main trial of Study 1)

- ErgativeStudy_PracticeAnimations.zip

a. Ergative_Judgment_PracticeAnimations (contains animations and audio files that accompanied the animations in the practice trial of Study 1)

b. Ergative_Production_PracticeAnimations (contains animations and audio files that accompanied the animations in the practice trial of Study 2)

- ErgativeStudy_VerbLists_Practice&Main.zip

a. Ergative_Hindi_VerbLists.xlsx (contains three sub-sheets which have details on the verbs that were used for adults and children - one adult list; two child lists - Child_List1, Child_List2)

b. ErgativeGJ_PracticeTrialsList.xlsx (contains list of the trials used for the grammatical judgment practice task in Study 1)

c. Ergative_EP_PracticeTrialsList.xlsx (contains list of the trials used for the elicited production practice task in Study 1)

- Ergative_SemanticsTaskMaterials.zip (contains materials used in the semantics ratings task)

- ErgativeStudy_Data&RCode-ORE.zip

a. Judgment_Study_Data (contains data and R code for Study 1)
  - finalrawdata-wp2-GJ-5-6-nopreemp.csv (raw data for 5–6 year olds)
  - finalrawdata-wp2-GJ-9-10-nopreemp.csv (raw data for 9–10 year olds)
  - finalrawdata-wp2-GJ-adults-nopreemp.csv (raw data for adults)
  - PreemptionCounts.csv (contains the frequency counts for all 40 verbs)
  - raw-semantics-20.csv (contains the raw data obtained from 20 participants on the semantics ratings task)
  - semantics-20-mean scores.xlsx (contains the mean ratings across participants for each verb on the semantics ratings task)
  - V2_Ergative_Judgments.R (R code for Study 1)

b. Production_Study_Data (contains data and R code for Study 2)
  - Production_FinalCodeSheet_4–5 (contains raw data from 4–5 year olds)
  - Production_FinalCodeSheet_5–6 (contains raw data from 5–6 year olds)
  - PreemptionCounts.csv (contains the frequency counts for all 40 verbs)

- raw-semantics-20.csv (contains the raw data obtained from 20 participants on the semantics ratings task)

- semantics-20-mean scores.xlsx (contains the mean ratings across participants for each verb on the semantics ratings task)

- Ergative_Prod.R (R code for Study 2)

Extended data

OSF: CLASS: Cross Linguistic Acquisition of Sentence Structure

https://doi.org/10.17605/OSF.IO/PAVM7 (Ambridge *et al.*, 2023b).

This project contains the following extended data:

❓ **Aaricia Ponnet** (ID)

Linguistics, Ghent University, Pietersnieuwstraat, Gent, Belgium

This article adds some fundamental findings to ongoing research about how children learn certain verbal constructions and how they deal with exceptions and semantic restrictions when learning verbal event constructions. Moreover, they do this by focussing on Hindi, a language which is, despite being the third most spoken language in the world, still under-researched in linguistic research and especially in research with a language acquisition and learnability perspective. Moreover, the study focuses on child speakers of Hindi in India of two different age groups (with a younger pilot study group) as well as a group of adult speakers. This means that the study not only provides interesting data from a learnability perspective (i.e. how do children deal with learning the different semantic and syntactic restrictions that are related to the acquisition of the construction under study) but also adds to the growing body of work on the Hindi language and additionally gives valuable insights on the distribution of *ne* marking with adult speakers of Hindi in India. It taps into to the body of work that researches the use and acquisition of differential case marking with children and adults, in this case, split ergativity (with a focus on active, transitive, two-participant verbs).

One of the strong points of this study is that it not only provides a wide range of data with considerably large sample groups with more than 140 participants in total (given that this type of research in India is still rather novel, and given the restrictions during the COVID pandemic during which this research has been performed, this is quite an impressive number), but it also provides a solid hypothesis and contrasts two different linguistic theoretical approaches that the study aims to test by analysing the data of the different speaker groups. On the one hand, the study aims to predict and test 'statistical preemption' (based on recent work by Goldberg and collaborators) which poses that certain constructions or linguistic forms probabilistically outcompete others in the input distribution of children, which means that they will prefer certain constructions or forms over others. On the other, the study aims to elaborate on previous work on the role of semantics in the learnability of certain constructions (building on previous work by Ambridge and collaborators), and typological work on Hindi (a.o. Mohanan 1994) that highlights the effects of verb-level semantics, in the case of split ergativity: transitivity, and clause level semantics, in the case of split ergativity: volitionality or intentionality. Verbs that rate higher on the transitivity cline

or that are associated with a higher sense of intentionality are predicted to be associated with *ne* with a higher range of frequency. It is important to note that the study focuses on active, transitive, two-participant verbs – intransitive verbs that can in some cases take the ergative were not included.

Data were collected using an acceptability judgment task (three groups, children of different age groups and adults) and an elicited production task (two groups, a younger group and a group aged 5-6). These are presented as two separate studies (study 1 and study 2), after which the results are compared in the discussion section. Study 1 looks at the effect of statistical preemption, intentionality and transitivity. Study 2 investigates the effect of statistical preemption and transitivity. A large online Hindi corpus was perused to account for statistical preemption with regard to the quantitative analysis. Another strong feature of the study is that it openly shares the material that was used to collect the data online, as well as the analyses in R. This means that the study is replicable, but also that reviewers and readers can have all the necessary information needed to interpret and check the results of this study.

Both the studies (acceptability judgment and elicited production) find an effect of statistical preemption over the different age groups (except for the middle age group in Study 1). In Study 1, additionally, a significant effect for intentionality was attested, but not for transitivity. In Study 2, to a lesser extent, an effect was found also for transitivity. This leads the authors to the conclusion that children rely both on frequency as well as semantics to learn certain regularities as well as exceptions to these regularities. In the case of ergative *ne* marking then, and specifically with regard to transitive perfective verbs, children learn, according to the authors, on a verb-by-verb basis, and with those verbs where *ne* marking is optional in particular, are further guided by semantics, in this case, intentionality. As per my knowledge, this is the first study on Hindi ergative marking that has been carried out at such a large scale, which makes it a necessary, innovative contribution to the field of linguistics.

The study is in my opinion a valuable and perhaps even groundbreaking contribution with regard to the several aspects that I summarized and highlighted above. I do have, however, some minor reservations/questions regarding the following:
   ○ A list of the 40 verbs is given in an online repository, but for the interpretation of the results of the study, I find it essential to include at least an overview of the verbs in the article itself (preferably with the original Hindi verb as well as its English counterpart).

   ○ In Hindi, the subject is generally null-marked (nominative). What makes the split ergative construction in Hindi challenging is that there is an opposition between ergative *ne* marking and nominative *null* marking. Children have to learn that the opposition transitive/intransitive is morphologically marked with verbs that have the perfective aspect. The verbs that have been included in this study only concern verbs that can have ergative marking but not typical intransitive verbs such as *jaanaa* 'to go', *bhaagnaa* 'to run', *baiThnaa* 'to sit', *khaaMsnaa* 'to cough', *naacnaa* 'to dance' and so on, neither does it include such intransitive verbs that can sometimes have subject marked with the ergative such as *chiikh* 'to scream'. On the one hand, this focus on two-participant transitive verbs could be made clearer in the introduction of the study (and, consequently, the exclusion of single-participant intransitive verbs), on the other hand, the inclusion of intransitive perfective verbs is in my opinion elementary to the research of the learnability of split ergativity as a whole, not only the semantics that are involved but also the morphosyntactic opposition

between ergative and nominative. This is particularly so since there are certain intransitive verbs that allow for *ne* marking when volitionality/intentionality is at play – and these verbs were not included in the study. Moreover, when testing statistical preemption, there will also be a role of the frequency of certain lemmas in the subject function – there can only be *ne* marking of the subject in the perfective aspect verb form, all other aspects have nominative subjects. Since other verb forms were not included in the study, the effect of frequency of nominative on the subject forms is therefore not accounted for in this study. Especially from a language development perspective, the question remains how children shift from mainly nominative to mainly ergative – if such a shift is present at all. This aspect is not covered by the study as most of the age groups perform similarly to the adult group, which suggests that by age 4-5 these nuances are already acquired.

○ Another issue regards the rating of the affectedness of the patient to rate the level of transitivity, by which the authors aim to test the influence of verb-level semantics on the use of *ne* with active, transitive two-participant verbs. This was tested by presenting participants passivized forms of the 40 verbs that were included in the test. My concern is that the effect of transitivity cannot be entirely tested in this way. Moreover, with regard to the transitivity cline, there are several aspects that have been stated by Hopper & Thompson (1980) that influence the level of transitivity, which concerns the agent as well as the patient. Moreover, according to Hopper & Thompson (1980), transitivity is "a global property of an entire clause" (251). Maitreyee et al. distinguish between intentionality at the clause level and transitivity as verb-level semantics, while these features may very well both be positioned at the clause level. Either the choice for this distinction at the semantic level needs to be made more clear by the authors in the text, or the focus should be more on 'patient affectedness' and less on transitivity, as transitivity encompasses more than affectedness alone. Moreover, volitionality/agentivity (which highly overlaps with the feature 'intentionality' that is being investigated in this study) is one of the features stated by Hopper and Thompson that influences the rate of transitivity as well (252). Within this line of reasoning, the authors have researched the effect of two transitivity features on the use of *ne* (i.e. intentionality vs. patient affectedness) rather than intentionality vs. transitivity.

○ Intentionality was tested by presenting the participants with four sentences, alternately marked with *ne* or null-marked in the nominative, and by adding an adverb *galtii se* 'by mistake'. In this way sentences were created that were, according to the authors, more intentional than others within the meaning of that particular verb. However, 1) an adverb expressing higher intentionality was not added, and 2) the range of intentionality between the different verbs that were tested was not accounted for. The figures in the article show a clear difference between sentences that have the adverb 'by mistake' and verbs that have not, which confirms a successful operationalization of 'less intentional', but there is also a cline to be observed between the verbs at the same level of intentionality. This probably goes beyond the scope of the study but confirms that differences in intentionality are inherent to the verbs and not solely attributable to the addition of adverbs. Moreover, actions with intransitive verbs can also be highly intentional (consider, e.g., to laugh and constructions such as laughing with vs. laughing at) and intentionality thus inevitably also interacts with the discourse-pragmatic level. I would have expected the authors to mention this briefly in the discussion section of the study.

○ I believe these data and analyses are extremely valuable and I hope that for future

research, the researchers are considering adding a qualitative component as well. From a language development perspective, I would have loved to see a few cases and example sentences highlighted that give us more insight into the details of the acquisition and use of ergative marking with Hindi-speaking children. This evidently goes beyond the scope of the study, but a qualitative analysis will give us more information on the between-verb differences in use at the same level as what the authors operationalised as intentionality and transitivity, as well as interindividual differences, between the different age groups as well as between the different participants within the same age group. Is there a learning curve or have all these children indeed acquired the semantic and syntactic constraints? Are some verbs more difficult than others? What were the highest or clearest contrasts in language use in the use of ergative marking within the adult groups, and what does that tell us about the regularity vs. optionality of *ne* marking, vs. the different features that interact with *ne* marking? I applaud the authors for creating the possibility of answering such questions with their collected data and am excited to read more of their work in the future.

Please find an annotated pdf of the article with further comments here.

Is the work clearly and accurately presented and does it engage with the current literature?
Yes

Is the study design appropriate and is the work technically sound?
Yes

Are sufficient details of methods and analysis provided to allow replication by others?
Yes

Are all the source data and materials underlying the results available?
Yes

If applicable, is the statistical analysis and its interpretation appropriate?
I cannot comment. A qualified statistician is required.

Are the conclusions drawn adequately supported by the results?
Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Second language acquisition, Hindi, General Linguistics, Morphosyntax, Syntax-semantics interface, differential case marking

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

This paper addresses the long-standing question of how speakers learn lexical restrictions on construction use in a new (to this literature) language, Hindi. It argues that the choice of the ergative particle 'ne' is constrained by both semantic transitivity of the sentence and the specific verb, with the verbs that most often occur with 'ne' being judged as less acceptable without it. This latter effect is said to provide evidence for statistical preemption. 6-year-olds, 10-year-olds and adults are tested. The effects of preemption / lexical idiosyncrasy are stronger than those of semantics.

The paper makes a valuable contribution to the literature by extending this debate to a new language, and a new construction. There is also methodological innovation in developing a way to rate semantic transitivity. Another strength of the paper is that both judgments and production data are collected.

One aspect of the paper that is not clear to me is whether it actually tests preemption. The tested prediction is "the greater the frequency with which a particular verb appears with versus without *ne* marking on the subject – relative to other verbs in the test set – the greater the extent to which *ne* marked forms will be preferred over zero-marked forms in the judgment task... we operationalized this measure using a scaled and centred chi-square statistic which measures how often, in past tense/perfective aspect active sentences, a particular verb triggers ergative case marking as compared with all other verbs in the test set of 40". However, this conflates frequency in the rated construction (e.g., with ne) and frequency in the other construction (without ne). The latter is an implementation of preemption but the former is not. How do we know that frequency in the other construction matters for the judgments? One way to address this issue would be to include frequency in the presented construction as a separate predictor. Less of an issue, but this also does not necessarily differentiate preemption and entrenchment, the frequency with which the verb occurs in other constructions that are not synonymous with the 'ne'.

A limitation of the analyses is that no interactions between age/subject group and the other predictors are fitted. These would show whether the effects of preemption and semantics actually change significantly over the tested age span.

This article explores how children learn semi-regular systems (exceptions-filled generalizations) in languages through an example of ergative case marking in Hindi which shows irregularity in that it appears in sentences with transitive verbs in perfective aspect and in sentences with some intransitive verbs that involve volitionality but not with intransitive verbs that lack volitionality also in perfective aspect, also they may be optional in sentences with intransitive verbs. Authors are interested in testing whether such systems are learnt as probabilistic generalizations or as formal rules with memorized exceptions (semantically restricted generalizations). Authors conduct a grammaticality judgement task and an elicited production task to test the probabilistic generalization hypothesis and the semantically restricted generalization hypothesis for learning semi-regular systems.

For the probabilistic generalization hypothesis, they study whether the ne-marked forms' frequency compared to zero-marked forms' frequency with a particular verb has an impact on its acceptability or production. To test the hypothesis about learning guided by semantic rules, e.g., only verbs high on transitivity trigger ergative ne-marking, they study the extent of ne- vs zero-marked subjects appearing with verbs rated higher on transitivity as being acceptable or produced. To test the semantics hypothesis at the verb-level, transitivity is operationalized in terms of the degree to which the patient is affected by the action denoted by the verb. To test the

semantics hypothesis at the clause-level, authors study the impact of an action appearing intentional rather than unintentional on the extent to which ne-marking forms compared to zero-marked forms are rated as acceptable.

Authors recruited children in age groups 5-6 and 9-10 and adults in their studies. The studies' results indicated that learners acquire exceptions-filled generalizations by learning probabilistically based on the input as well as forming overarching semantic generalizations and learning semantics based exceptions to avoid overgeneralization. The probabilistic generalization (statistical preemption) effects were observed across the board. In terms of semantics, authors observed that learners were sensitive to a clause level semantic constraint involving intentionality of the actions. Authors found limited evidence for the effect of verb-level semantics (patient affectedness), however for adults this effect was observed indicating potential historical links between patient-affectedness and whether the verb would come to prefer ne vs zero marking.

The work is presented in the paper clearly. The study design is appropriate, and sufficient details are provided about the study design as well as methods and analyses used for the studies in general. The work is technically sound. Authors have made the data they prepared and used in their studies publicly available which will make the replication of the work possible as well as provide data for further analyses and for use in further studies. In my understanding, the statistical analyses and the interpretations seem appropriate, however a statistician may provide further comments. The conclusions are well-supported.

Regarding the 40 selected action verbs, did authors look at the inter-annotator agreement between the two native speakers providing intuitions about the action verbs whether they appeared with ergative ne-marking zero-marking or optional ne-marking?
